Part I

Chapter 1

The base package

base-package	<i>The R Base Package</i>
--------------	---------------------------

Description

Base R functions

Details

This package contains the basic functions which let R function as a language: arithmetic, input/output, basic programming support, etc. Its contents are available through inheritance from any environment.

For a complete list of functions, use `library(help = "base")`.

<code>.bincode</code>	<i>Bin a Numeric Vector</i>
-----------------------	-----------------------------

Description

Bin a numeric vector and return integer codes for the binning.

Usage

```
.bincode(x, breaks, right = TRUE, include.lowest = FALSE)
```

Arguments

<code>x</code>	a numeric vector which is to be converted to integer codes by binning.
<code>breaks</code>	a numeric vector of two or more cut points, sorted in increasing order.
<code>right</code>	logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
<code>include.lowest</code>	logical, indicating if an 'x[i]' equal to the lowest (or highest, for <code>right = FALSE</code>) 'breaks' value should be included in the first (or last) bin.

Details

This is a ‘barebones’ version of `cut.default(labels = FALSE)` intended for use in other functions which have checked the arguments passed. (Note the different order of the arguments they have in common.)

Unlike `cut`, the `breaks` do not need to be unique. An input can only fall into a zero-length interval if it is closed at both ends, so only if `include.lowest = TRUE` and it is the first (or last for `right = FALSE`) interval.

Value

An integer vector of the same length as `x` indicating which bin each element falls into (the leftmost bin being bin 1). `NaN` and `NA` elements of `x` are mapped to `NA` codes, as are values outside range of `breaks`.

See Also

`cut`, `tabulate`

Examples

```
## An example with non-unique breaks:
x <- c(0, 0.01, 0.5, 0.99, 1)
b <- c(0, 0, 1, 1)
.bincode(x, b, TRUE)
.bincode(x, b, FALSE)
.bincode(x, b, TRUE, TRUE)
.bincode(x, b, FALSE, TRUE)
```

.Device

Lists of Open/Active Graphics Devices

Description

A pairlist of the names of open graphics devices is stored in `.Devices`. The name of the active device (see `dev.cur`) is stored in `.Device`. Both are symbols and so appear in the base namespace.

Usage

```
.Device
.Devices
```

Details

`.Device` is a length-one character vector.

`.Devices` is a [pairlist](#) of length-one character vectors. The first entry is always "null device", and there are as many entries as the maximal number of graphics devices which have been simultaneously active. If a device has been removed, its entry will be "" until the device number is reused.

Devices may add attributes to the character vector: for example devices which write to a file may record its path in attribute "filepath".

`.Machine`

Numerical Characteristics of the Machine

Description

`.Machine` is a variable holding information on the numerical characteristics of the machine R is running on, such as the largest double or integer and the machine's precision.

Usage

```
.Machine
```

Details

The algorithm is based on subroutine MACHAR (Cody 1988). As all current implementations of R use 32-bit integers and use IEC 60559 floating-point (double precision) arithmetic, the "integer" and "double" related values are the same for almost all R builds.

Note that on most platforms smaller positive values than `.Machine$double.xmin` can occur. On a typical R platform the smallest positive double is about $5e-324$.

Value

A list with components

`double.eps` the smallest positive floating-point number x such that $1 + x \neq 1$. It equals $\text{double.base}^{\text{ulp.digits}}$ if either `double.base` is 2 or `double.rounding` is 0; otherwise, it is $(\text{double.base}^{\text{double.ulp.digits}}) / 2$. Normally $2.220446e-16$.

`double.neg.eps` a small positive floating-point number x such that $1 - x \neq 1$. It equals $\text{double.base}^{\text{double.neg.ulp.digits}}$ if `double.base` is 2 or `double.rounding` is 0; otherwise, it is $(\text{double.base}^{\text{double.neg.ulp.digits}}) / 2$. Normally $1.110223e-16$. As `double.neg.ulp.digits` is bounded below by $-(\text{double.digits} + 3)$, `double.neg.eps` may not be the smallest number that can alter 1 by subtraction.

`double.xmin` the smallest non-zero normalized floating-point number, a power of the radix, i.e., $\text{double.base}^{\text{double.min.exp}}$. Normally $2.225074e-308$.

`double.xmax` the largest normalized floating-point number. Typically, it is equal to $(1 - \text{double.neg.eps}) * \text{double.base}^{\text{double.max.exp}}$, but on some machines it is only the second or third largest such number, being too small by 1 or 2 units in the last digit of the significand. Normally $1.797693e+308$. Note that larger unnormalized numbers can occur.

`double.base` the radix for the floating-point representation: normally 2.

`double.digits` the number of base digits in the floating-point significand: normally 53.

`double.rounding` the rounding action, one of
 0 if floating-point addition chops;
 1 if floating-point addition rounds, but not in the IEEE style;

2 if floating-point addition rounds in the IEEE style;
 3 if floating-point addition chops, and there is partial underflow;
 4 if floating-point addition rounds, but not in the IEEE style, and there is partial underflow;
 5 if floating-point addition rounds in the IEEE style, and there is partial underflow.
 Normally 5.

`double.guard` the number of guard digits for multiplication with truncating arithmetic. It is 1 if floating-point arithmetic truncates and more than `double.digits` base-`double.base` digits participate in the post-normalization shift of the floating-point significand in multiplication, and 0 otherwise.
 Normally 0.

`double.ulp.digits` the largest negative integer i such that $1 + \text{double.base}^i \neq 1$, except that it is bounded below by $-(\text{double.digits} + 3)$. Normally -52.

`double.neg.ulp.digits` the largest negative integer i such that $1 - \text{double.base}^i \neq 1$, except that it is bounded below by $-(\text{double.digits} + 3)$. Normally -53.

`double.exponent` the number of bits (decimal places if `double.base` is 10) reserved for the representation of the exponent (including the bias or sign) of a floating-point number. Normally 11.

`double.min.exp` the largest in magnitude negative integer i such that double.base^i is positive and normalized. Normally -1022.

`double.max.exp` the smallest positive power of `double.base` that overflows. Normally 1024.

`integer.max` the largest integer which can be represented. Always $2^{31} - 1 = 2147483647$.

`sizeof.long` the number of bytes in a C 'long' type: 4 or 8 (most 64-bit systems, but not Windows).

`sizeof.longlong` the number of bytes in a C 'long long' type. Will be zero if there is no such type, otherwise usually 8.

`sizeof.longdouble` the number of bytes in a C 'long double' type. Will be zero if there is no such type (or its use was disabled when R was built), otherwise possibly 12 (most 32-bit builds), 16 (most 64-bit builds) or 8 (CPUs such as ARM where for most compilers 'long double' is identical to double).

`sizeof.pointer` the number of bytes in the C SEXP type. Will be 4 on 32-bit builds and 8 on 64-bit builds of R.

`sizeof.time_t` the number of *bytes* in the C `time_t` type: a 64-bit `time_t` (value 8) is much preferred these days. Note that this is the type used by code in R itself, not necessarily the *system* type if R was configured with '--with-internal-tzcode' as also used on Windows.

`longdouble.eps`, `longdouble.neg.eps`, `longdouble.digits`, ... introduced in R 4.0.0. When `capabilities("long.double")` is true, there are 10 such "`longdouble.kind`" values, specifying the 'long double' property corresponding to its "`double.*`" counterpart. See also 'Note'.

Note

In the (typical) case where `capabilities("long.double")` is true, R uses the ‘long double’ C type in quite a few places internally for accumulators in e.g. `sum`, reading non-integer numeric constants into (binary) double precision numbers, or arithmetic such as `x %% y`; also, ‘long double’ can be read by `readBin`.

For this reason, in that case, `.Machine` contains ten further components, `longdouble.eps`, `*.neg.eps`, `*.digits`, `*.rounding*.guard`, `*.ulp.digits`, `*.neg.ulp.digits`, `*.exponent`, `*.min.exp`, and `*.max.exp`, computed entirely analogously to their `double.*` counterparts, see there.

`sizeof.longdouble` only tells you the amount of storage allocated for a long double. Often what is stored is the 80-bit extended double type of IEC 60559, padded to the double alignment used on the platform — this seems to be the case for the common R platforms using ix86 and x86_64 chips. There are other implementation of long double, usually in software for example on Sparc Solaris and AIX.

Note that it is legal for a platform to have a ‘long double’ C type which is identical to the ‘double’ type — this happens on ARM CPUs. In that case `capabilities("long.double")` will be false but on versions of R prior to 4.0.4, `.Machine` may contain `"longdouble.kind"` elements.

Source

Uses a C translation of Fortran code in the reference, modified by the R Core Team to defeat over-optimization in modern compilers.

See Also

`.Platform` for details of the platform.

Examples

```
.Machine
## or for a neat printout
noquote(unlist(format(.Machine)))
```

`.Platform`
Platform Specific Variables

Description

`.Platform` is a list with some details of the platform under which R was built. This provides means to write OS-portable R code.

Usage

```
.Platform
```

Value

A list with at least the following components:

<code>OS.type</code>	character string, giving the Operating System (family) of the computer. One of "unix" or "windows".
<code>file.sep</code>	character string, giving the file separator used on your platform: "/" on both Unix-alikes <i>and</i> on Windows (but not on the former port to Classic Mac OS).
<code>dynlib.ext</code>	character string, giving the file name extension of dynamically loadable libraries , e.g., ".dll" on Windows and ".so" or ".sl" on Unix-alikes. (Note for macOS users: these are shared objects as loaded by <code>dyn.load</code> and not dylibs: see <code>dyn.load</code> .)
<code>GUI</code>	character string, giving the type of GUI in use, or "unknown" if no GUI can be assumed. Possible values are for Unix-alikes the values given via the '-g' command-line flag ("X11", "Tk"), "AQUA" (running under <code>R.app</code> on macOS), "Rgui" and "RTerm" (Windows) and perhaps others under alternative front-ends or embedded R.
<code>endian</code>	character string, "big" or "little", giving the 'endianness' of the processor in use. This is relevant when it is necessary to know the order to read/write bytes of e.g. an integer or double from/to a connection : see <code>readBin</code> .
<code>pkgType</code>	character string, the preferred setting for <code>options("pkgType")</code> . Values "source", "mac.binary" and "win.binary" are currently in use. This should not be used to identify the OS.
<code>path.sep</code>	character string, giving the path separator , used on your platform, e.g., ":" on Unix-alikes and ";" on Windows. Used to separate paths in environment variables such as <code>PATH</code> and <code>TEXINPUTS</code> .
<code>r_arch</code>	character string, possibly "". The name of an architecture-specific directory used in this build of R.

AQUA

`.Platform$GUI` is set to "AQUA" under the macOS GUI, `R.app`. This has a number of consequences:

- `"/usr/local/bin"` is *appended* to the `PATH` environment variable.
- the default graphics device is set to `quartz`.
- selects native (rather than Tk) widgets for the `graphics = TRUE` options of `menu` and `select.list`.
- HTML help is displayed in the internal browser.
- the spreadsheet-like data editor/viewer uses a Quartz version rather than the X11 one.

See Also

`R.version` and `Sys.info` give more details about the OS. In particular, `R.version$platform` is the canonical name of the platform under which R was compiled. `osVersion` may give more details about the platform R is running on.

`.Machine` for details of the arithmetic used, and `system` for invoking platform-specific system commands.

`capabilities` and `extSoftVersion` (and links there) for availability of capabilities partly *external* to R but used from R functions.

Examples

```
## Note: this can be done in a system-independent way by dir.exists()
if(.Platform$OS.type == "unix") {
  system.test <- function(...) system(paste("test", ...)) == 0L
  dir.exists2 <- function(dir)
    sapply(dir, function(d) system.test("-d", d))
  dir.exists2(c(R.home(), "/tmp", "~", "/NO")) # > T T T F
}
```

abbreviate

Abbreviate Strings

Description

Abbreviate strings to at least `minlength` characters, such that they remain *unique* (if they were), unless `strict = TRUE`.

Usage

```
abbreviate(names.arg, minlength = 4, use.classes = TRUE,
           dot = FALSE, strict = FALSE,
           method = c("left.kept", "both.sides"), named = TRUE)
```

Arguments

<code>names.arg</code>	a character vector of names to be abbreviated, or an object to be coerced to a character vector by as.character .
<code>minlength</code>	the minimum length of the abbreviations.
<code>use.classes</code>	logical: should lowercase characters be removed first?
<code>dot</code>	logical: should a dot (".") be appended?
<code>strict</code>	logical: should <code>minlength</code> be observed strictly? Note that setting <code>strict = TRUE</code> may return <i>non-unique</i> strings.
<code>method</code>	a character string specifying the method used with default "left.kept", see 'Details' below. Partial matches allowed.
<code>named</code>	logical: should <code>names</code> (with original vector) be returned.

Details

The default algorithm (`method = "left.kept"`) used is similar to that of `S`. For a single string it works as follows. First spaces at the ends of the string are stripped. Then (if necessary) any other spaces are stripped. Next, lower case vowels are removed followed by lower case consonants. Finally if the abbreviation is still longer than `minlength` upper case letters and symbols are stripped.

Characters are always stripped from the end of the strings first. If an element of `names.arg` contains more than one word (words are separated by spaces) then at least one letter from each word will be retained.

Missing (NA) values are unaltered.

If `use.classes` is `FALSE` then the only distinction is to be between letters and space.

Value

A character vector containing abbreviations for the character strings in its first argument. Duplicates in the original `names.arg` will be given identical abbreviations. If any non-duplicated elements have the same `minlength` abbreviations then, if `method = "both.sides"` the basic internal `abbreviate()` algorithm is applied to the characterwise *reversed* strings; if there are still duplicated abbreviations and if `strict = FALSE` as by default, `minlength` is incremented by one and new abbreviations are found for those elements only. This process is repeated until all unique elements of `names.arg` have unique abbreviations.

If `names` is `true`, the character version of `names.arg` is attached to the returned value as a `names` attribute: no other attributes are retained.

If an input element contains non-ASCII characters, the corresponding value will be in UTF-8 and marked as such (see [Encoding](#)).

Warning

If `use.classes` is `true` (the default), this is really only suitable for English, and prior to R 3.3.0 did not work correctly with non-ASCII characters in multibyte locales. It will warn if used with non-ASCII characters (and required to reduce the length). Note that the result may depend on `Sys.getlocale("LC_CTYPE")`, and e.g., for the "C" locale currently may depend on the platform, at least macOS behaving differently. It is unlikely to work well with inputs not in the Unicode Basic Multilingual Plane nor on (rare) platforms where wide characters are not encoded in Unicode.

As from R 3.3.0 the concept of ‘vowel’ is extended from English vowels by including characters which are accented versions of lower-case English vowels (including ‘o with stroke’). Of course, there are languages (even Western European languages such as Welsh) with other vowels.

See Also

[substr](#).

Examples

```
x <- c("abcd", "efgh", "abce")
abbreviate(x, 2)
abbreviate(x, 2, strict = TRUE) # >> 1st and 3rd are == "ab"

(st.abb <- abbreviate(state.name, 2))
stopifnot(identical(unname(st.abb),
  abbreviate(state.name, 2, named=FALSE)))
table(nchar(st.abb)) # out of 50, 3 need 4 letters :
as <- abbreviate(state.name, 3, strict = TRUE)
as[which(as == "Mss")]

## and without distinguishing vowels:
st.abb2 <- abbreviate(state.name, 2, FALSE)
cbind(st.abb, st.abb2)[st.abb2 != st.abb, ]

## method = "both.sides" helps: no 4-letters, and only 4 3-letters:
st.ab2 <- abbreviate(state.name, 2, method = "both")
table(nchar(st.ab2))
## Compare the two methods:
cbind(st.abb, st.ab2)
```

agrep

*Approximate String Matching (Fuzzy Matching)***Description**

Searches for approximate matches to `pattern` (the first argument) within each element of the string `x` (the second argument) using the generalized Levenshtein edit distance (the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another).

Usage

```
agrep(pattern, x, max.distance = 0.1, costs = NULL,
       ignore.case = FALSE, value = FALSE, fixed = TRUE,
       useBytes = FALSE)

agrep1(pattern, x, max.distance = 0.1, costs = NULL,
        ignore.case = FALSE, fixed = TRUE, useBytes = FALSE)
```

Arguments

<code>pattern</code>	a non-empty character string to be matched. For <code>fixed = FALSE</code> this should contain an extended regular expression . Coerced by as.character to a string if possible.
<code>x</code>	character vector where matches are sought. Coerced by as.character to a character vector if possible.
<code>max.distance</code>	maximum distance allowed for a match. Expressed either as integer, or as a fraction of the <i>pattern</i> length times the maximal transformation cost (will be replaced by the smallest integer not less than the corresponding fraction), or a list with possible components <code>cost</code>: maximum number/fraction of match cost (generalized Levenshtein distance) <code>all</code>: maximal number/fraction of <i>all</i> transformations (insertions, deletions and substitutions) <code>insertions</code>: maximum number/fraction of insertions <code>deletions</code>: maximum number/fraction of deletions <code>substitutions</code>: maximum number/fraction of substitutions If <code>cost</code> is not given, <code>all</code> defaults to 10%, and the other transformation number bounds default to <code>all</code>. The component names can be abbreviated.
<code>costs</code>	a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the generalized Levenshtein distance, or <code>NULL</code> (default) indicating using unit cost for all three possible transformations. Coerced to integer via as.integer if possible.
<code>ignore.case</code>	if <code>FALSE</code> , the pattern matching is <i>case sensitive</i> and if <code>TRUE</code> , case is ignored during matching.
<code>value</code>	if <code>FALSE</code> , a vector containing the (integer) indices of the matches determined is returned and if <code>TRUE</code> , a vector containing the matching elements themselves is returned.

<code>fixed</code>	logical. If <code>TRUE</code> (default), the pattern is matched literally (as is). Otherwise, it is matched as a regular expression.
<code>useBytes</code>	logical. If <code>TRUE</code> the matching is done byte-by-byte rather than character-by-character. See ‘Details’.

Details

The Levenshtein edit distance is used as measure of approximateness: it is the (possibly cost-weighted) total number of insertions, deletions and substitutions required to transform one string into another.

This uses the `tre` code by Ville Laurikari (<https://github.com/laurikari/tre>), which supports MBCS character matching.

The main effect of `useBytes = TRUE` is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes" (see [Encoding](#)).

Value

`agrep` returns a vector giving the indices of the elements that yielded a match, or, if `value` is `TRUE`, the matched elements (after coercion, preserving names but no other attributes).

`agrep1` returns a logical vector.

Note

Since someone who read the description carelessly even filed a bug report on it, do note that this matches substrings of each element of `x` (just as `grep` does) and **not** whole elements. See also `adist` in package `utils`, which optionally returns the offsets of the matched substrings.

Author(s)

Original version in R < 2.10.0 by David Meyer. Current version by Brian Ripley and Kurt Hornik.

See Also

`grep`, `adist`. A different interface to approximate string matching is provided by `aregexec()`.

Examples

```
agrep("lasy", "1 lazy 2")
agrep("lasy", c(" 1 lazy 2", "1 lasy 2"), max.distance = list(sub = 0))
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max.distance = 2)
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max.distance = 2, value = TRUE)
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max.distance = 2, ignore.case = TRUE)
```

all	<i>Are All Values True?</i>
-----	-----------------------------

Description

Given a set of logical vectors, are all of the values true?

Usage

```
all(..., na.rm = FALSE)
```

Arguments

...	zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.
na.rm	logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a [primitive](#) function.

Value

The value is a logical vector of length one.

Let x denote the concatenation of all the logical vectors in ... (after coercion), after removing NAs if requested by `na.rm = TRUE`.

The value returned is `TRUE` if all of the values in x are `TRUE` (including if there are no values), and `FALSE` if at least one of the values in x is `FALSE`. Otherwise the value is `NA` (which can only occur if `na.rm = FALSE` and ... contains no `FALSE` values and at least one `NA` value).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature $x, \dots, na.rm$.

Note

That `all(logical(0))` is true is a useful convention: it ensures that

```
all(all(x), all(y)) == all(x, y)
```

even if x has length zero.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[any](#), the ‘complement’ of `all`, and `stopifnot(*)` which is an `all(*)` ‘insurance’.

Examples

```
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(all(x < 0)) cat("all x values are negative\n")

all(logical(0)) # true, as all zero of the elements are true.
```

all.equal	<i>Test if Two Objects are (Nearly) Equal</i>
-----------	---

Description

`all.equal(x, y)` is a utility to compare R objects `x` and `y` testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Do not use `all.equal` directly in `if` expressions—either use `isTRUE(all.equal(...))` or `identical` if appropriate.

Usage

```
all.equal(target, current, ...)

## Default S3 method:
all.equal(target, current, ..., check.class = TRUE)

## S3 method for class 'numeric'
all.equal(target, current,
          tolerance = sqrt(.Machine$double.eps), scale = NULL,
          countEQ = FALSE,
          formatFUN = function(err, what) format(err),
          ..., check.attributes = TRUE, check.class = TRUE, giveErr = FALSE)

## S3 method for class 'character'
all.equal(target, current, ...,
          check.attributes = TRUE, check.class = TRUE)

## S3 method for class 'list'
all.equal(target, current, ...,
          check.attributes = TRUE, use.names = TRUE)

## S3 method for class 'environment'
all.equal(target, current, all.names = TRUE,
          evaluate = TRUE, ...)

## S3 method for class 'function'
all.equal(target, current, check.environment=TRUE, ...)

## S3 method for class 'POSIXt'
all.equal(target, current, ..., tolerance = 1e-3, scale,
```

```
check.tzone = TRUE)
```

```
attr.all.equal(target, current, ...,
               check.attributes = TRUE, check.names = TRUE)
```

Arguments

target	R object.
current	other R object, to be compared with target.
...	further arguments for different methods, notably the following two, for numerical comparison:
tolerance	numeric ≥ 0 . Differences smaller than tolerance are not reported. The default value is close to $1.5e-8$.
scale	NULL or numeric > 0 , typically of length 1 or <code>length(target)</code> . See ‘Details’.
countEQ	logical indicating if the <code>target == current</code> cases should be counted when computing the mean (absolute or relative) differences. The default, FALSE may seem misleading in cases where target and current only differ in a few places; see the extensive example.
formatFUN	a function of two arguments, <code>err</code> , the relative, absolute or scaled error, and <code>what</code> , a character string indicating the <i>kind</i> of error; may be used, e.g., to format relative and absolute errors differently.
check.attributes	logical indicating if the attributes of target and current (other than the names) should be compared.
check.class	logical indicating if the <code>data.class()</code> of target and current should be compared.
giveErr	logical indicating if the result should contain the numerical error as an "err" attribute.
use.names	logical indicating if list comparison should report differing components by name (if matching) instead of integer index. Note that this comes after ... and so must be specified by its full name.
all.names	logical passed to ls indicating if “hidden” objects should also be considered in the environments.
evaluate	for the environment method: logical indicating if “promises should be forced”, i.e., typically formal function arguments be evaluated for comparison. If false, only the names of the objects in the two environments are checked for equality.
check.environment	logical requiring that the <code>environment()</code> s of functions should be compared, too. You may need to set <code>check.environment=FALSE</code> in unexpected cases, such as when comparing two <code>nls()</code> fits.
check.tzone	logical indicating if the "tzone" attributes of target and current should be compared.
check.names	logical indicating if the names(.) of target and current should be compared.

Details

`all.equal` is a generic function, dispatching methods on the `target` argument. To see the available methods, use `methods("all.equal")`, but note that the default method also does some dispatching, e.g. using the raw method for logical targets.

Remember that arguments which follow `...` must be specified by (unabbreviated) name. It is inadvisable to pass unnamed arguments in `...` as these will match different arguments in different methods.

Numerical comparisons for `scale = NULL` (the default) are typically on a *relative difference* scale unless the `target` values are close to zero or infinite. Specifically, the scale is computed as the mean absolute value of `target`. If this scale is finite and exceeds `tolerance`, differences are expressed relative to it; otherwise, absolute differences are used. Note that this scale and all further steps are computed only for those vector elements where `target` is not `NA` and differs from `current`. If `countEQ` is true, the equal and NA cases are *counted* in determining the “sample” size.

If `scale` is numeric (and positive), absolute comparisons are made after scaling (dividing) by `scale`. Note that if all of `scale` is close to 1 (specifically, within $1e-7$), the difference is still reported as being on an absolute scale.

For complex `target`, the modulus (`Mod`) of the difference is used: `all.equal.numeric` is called so arguments `tolerance` and `scale` are available.

The `list` method compares components of `target` and `current` recursively, passing all other arguments, as long as both are “list-like”, i.e., fulfill either `is.vector` or `is.list`.

The `environment` method works via the `list` method, and is also used for reference classes (unless a specific `all.equal` method is defined).

The method for date-time objects uses `all.equal.numeric` to compare times (in “POSIXct” representation) with a default `tolerance` of 0.001 seconds, ignoring `scale`. A time zone mismatch between `target` and `current` is reported unless `check.tzone = FALSE`.

`attr.all.equal` is used for comparing `attributes`, returning `NULL` or a character vector.

Value

Either `TRUE` (`NULL` for `attr.all.equal`) or a vector of mode “character” describing the differences between `target` and `current`.

See Also

`identical`, `isTRUE`, `==`, and `all` for exact equality testing.

Examples

```
all.equal(pi, 355/113)
# not precise enough (default tol) > relative error

quarts <- 1/4 + 1:10 # exact
d45 <- pi*quarts ; one <- rep(1, 10)
tan(d45) == one # mostly FALSE, as typically exact; embarrassingly,
```

```

tanpi(quarts) == one # (is always FALSE (Fedora 34; gcc 11.2.1))
stopifnot(all.equal(
  tan(d45), one)) # TRUE, but not if we are picky:
all.equal(tan(d45), one, tolerance = 0) # to see difference
all.equal(tan(d45), one, tolerance = 0, scale = 1) # "absolute diff.."
all.equal(tan(d45), one, tolerance = 0, scale = 1+(-2:2)/1e9) # "absolute"
all.equal(tan(d45), one, tolerance = 0, scale = 1+(-2:2)/1e6) # "scaled"

## advanced: equality of environments
ae <- all.equal(as.environment("package:stats"),
  asNamespace("stats"))
stopifnot(is.character(ae), length(ae) > 10,
  ## were incorrectly "considered equal" in R <= 3.1.1
  all.equal(asNamespace("stats"), asNamespace("stats")))

## A situation where 'countEQ = TRUE' makes sense:
x1 <- x2 <- (1:100)/10; x2[2] <- 1.1*x1[2]
## 99 out of 100 pairs (x1[i], x2[i]) are equal:
plot(x1,x2, main = "all.equal.numeric() -- not counting equal parts")
all.equal(x1,x2) ## "Mean relative difference: 0.1"
mtext(paste("all.equal(x1,x2) :", all.equal(x1,x2)), line=-2)
## 'extract the 'Mean relative difference' as number:
all.eqNum <- function(...) as.numeric(sub(".*:", '', all.equal(...)))
set.seed(17)
## When x2 is jittered, typically all pairs (x1[i],x2[i]) do differ:
summary(r <- replicate(100, all.eqNum(x1, x2*(1+rnorm(x1)*1e-7))))
mtext(paste("mean(all.equal(x1, x2*(1 + eps_k))) {100 x} Mean rel.diff.",
  signif(mean(r), 3)), line = -4, adj=0)
## With argument countEQ=TRUE, get "the same" (w/o need for jittering):
mtext(paste("all.equal(x1,x2, countEQ=TRUE) :",
  signif(all.eqNum(x1,x2, countEQ=TRUE), 3)), line= -6, col=2)

## Using giveErr=TRUE :
x1. <- x1 * (1+ 1e-9*rnorm(x1))
str(all.equal(x1, x1., giveErr=TRUE))
## logi TRUE
## - attr(*, "err")= num 8.66e-10
## - attr(*, "what")= chr "relative"

## Used with stopifnot(), still *showing* diff:
all.equalShow <- function (...) {
  r <- all.equal(..., giveErr=TRUE)
  cat(attr(r,"what"), "err:", attr(r,"err"), "\n")
  c(r) # can drop attributes, as not used anymore
}
# checks, showing error in any case:
stopifnot(all.equalShow(x1, x1.)) # -> relative err: 8.66002e-10
tryCatch(error=identity, stopifnot(all.equalShow(x1, 2*x1))) -> eAe
stopifnot(inherits(eAe, "error"))
# stopifnot(all.equal....()) giving smart msg:
cat(conditionMessage(eAe), "\n")

two <- structure(2, foo = 1, class = "bar")
all.equal(two^20, 2^20) # lots of diff
all.equal(two^20, 2^20, check.attributes = FALSE) # "target is bar, current is numeric"
all.equal(two^20, 2^20, check.attributes = FALSE, check.class = FALSE) # TRUE

```

```
## comparison of date-time objects
now <- Sys.time()
stopifnot(
  all.equal(now, now + 1e-4) # TRUE (default tolerance = 0.001 seconds)
)
all.equal(now, now + 0.2)
all.equal(now, as.POSIXlt(now, "UTC"))
stopifnot(
  all.equal(now, as.POSIXlt(now, "UTC"), check.tzone = FALSE) # TRUE
)
```

all.names

*Find All Names in an Expression***Description**

Return a character vector containing all the names which occur in an expression or call.

Usage

```
all.names(expr, functions = TRUE, max.names = -1L, unique = FALSE)
all.vars(expr, functions = FALSE, max.names = -1L, unique = TRUE)
```

Arguments

expr	an expression or call from which the names are to be extracted.
functions	a logical value indicating whether function names should be included in the result.
max.names	the maximum number of names to be returned. -1 indicates no limit (other than vector size limits).
unique	a logical value which indicates whether duplicate names should be removed from the value.

Details

These functions differ only in the default values for their arguments.

Value

A character vector with the extracted names.

See Also

[substitute](#) to replace symbols with values in an expression.

Examples

```
all.names(expression(sin(x+y)))
all.names(quote(sin(x+y))) # or a call
all.vars(expression(sin(x+y)))
```

any

Are Some Values True?

Description

Given a set of logical vectors, is at least one of the values true?

Usage

```
any(..., na.rm = FALSE)
```

Arguments

...	zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.
na.rm	logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a [primitive](#) function.

Value

The value is a logical vector of length one.

Let x denote the concatenation of all the logical vectors in ... (after coercion), after removing NAs if requested by `na.rm = TRUE`.

The value returned is `TRUE` if at least one of the values in x is `TRUE`, and `FALSE` if all of the values in x are `FALSE` (including if there are no values). Otherwise the value is `NA` (which can only occur if `na.rm = FALSE` and ... contains no `TRUE` values and at least one `NA` value).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature $x, \dots, na.rm$.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[all](#), the ‘complement’ of `any`.

Examples

```
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(any(x < 0)) cat("x contains negative values\n")
```

aperm

*Array Transposition***Description**

Transpose an array by permuting its dimensions and optionally resizing it.

Usage

```
aperm(a, perm, ...)
## Default S3 method:
aperm(a, perm = NULL, resize = TRUE, ...)
## S3 method for class 'table'
aperm(a, perm = NULL, resize = TRUE, keep.class = TRUE, ...)
```

Arguments

<code>a</code>	the array to be transposed.
<code>perm</code>	the subscript permutation vector, usually a permutation of the integers <code>1:n</code> , where <code>n</code> is the number of dimensions of <code>a</code> . When <code>a</code> has named <code>dimnames</code> , it can be a character vector of length <code>n</code> giving a permutation of those names. The default (used whenever <code>perm</code> has zero length) is to reverse the order of the dimensions.
<code>resize</code>	a flag indicating whether the vector should be resized as well as having its elements reordered (default <code>TRUE</code>).
<code>keep.class</code>	logical indicating if the result should be of the same class as <code>a</code> .
<code>...</code>	potential further arguments of methods.

Value

A transposed version of array `a`, with subscripts permuted as indicated by the array `perm`. If `resize` is `TRUE`, the array is reshaped as well as having its elements permuted, the `dimnames` are also permuted; if `resize = FALSE` then the returned object has the same dimensions as `a`, and the `dimnames` are dropped. In each case other attributes are copied from `a`.

The function `t` provides a faster and more convenient way of transposing matrices.

Author(s)

Jonathan Rougier, <J.C.Rougier@durham.ac.uk> did the faster C implementation.

See Also

[t](#), to transpose matrices.

Examples

```
# interchange the first two subscripts on a 3-way array x
x <- array(1:24, 2:4)
xt <- aperm(x, c(2,1,3))
stopifnot(t(xt[, , 2]) == x[, , 2],
           t(xt[, , 3]) == x[, , 3],
           t(xt[, , 4]) == x[, , 4])

UCB <- aperm(UCBAdmissions, c(2,1,3))
UCB[1, , ]
summary(UCB) # UCB is still a contingency table
```

append

Vector Merging

Description

Add elements to a vector.

Usage

```
append(x, values, after = length(x))
```

Arguments

<code>x</code>	the vector the values are to be appended to.
<code>values</code>	to be included in the modified vector.
<code>after</code>	a subscript, after which the values are to be appended.

Value

A vector containing the values in `x` with the elements of `values` appended after the specified element of `x`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Examples

```
append(1:5, 0:1, after = 3)
```

 apply

Apply Functions Over Array Margins

Description

Returns a vector or array or list of values obtained by applying a function to margins of an array or matrix.

Usage

```
apply(X, MARGIN, FUN, ..., simplify = TRUE)
```

Arguments

X	an array, including a matrix.
MARGIN	a vector giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns, <code>c(1, 2)</code> indicates rows and columns. Where X has named dimnames, it can be a character vector selecting dimension names.
FUN	the function to be applied: see ‘Details’. In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be backquoted or quoted.
...	optional arguments to FUN.
simplify	a logical indicating whether results should be simplified if possible.

Details

If X is not an array but an object of a class with a non-null `dim` value (such as a data frame), `apply` attempts to coerce it to an array via `as.matrix` if it is two-dimensional (e.g., a data frame) or via `as.array`.

FUN is found by a call to `match.fun` and typically is either a function or a symbol (e.g., a backquoted name) or a character string specifying a function to be searched for from the environment of the call to `apply`.

Arguments in ... cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to MARGIN or FUN. In general-purpose code it is good practice to name the first three arguments if ... is passed through: this both avoids partial matching to MARGIN or FUN and ensures that a sensible error message is given if arguments named X, MARGIN or FUN are passed through ...

Value

If each call to FUN returns a vector of length n, and simplify is TRUE, then `apply` returns an array of dimension `c(n, dim(X)[MARGIN])` if `n > 1`. If n equals 1, `apply` returns a vector if MARGIN has length 1 and an array of dimension `dim(X)[MARGIN]` otherwise. If n is 0, the result has length 0 but not necessarily the ‘correct’ dimension.

If the calls to FUN return vectors of different lengths, or if simplify is FALSE, `apply` returns a list of length `prod(dim(X)[MARGIN])` with dim set to MARGIN if this has length greater than one.

In all cases the result is coerced by `as.vector` to one of the basic vector types before the dimensions are set, so that (for example) factor results will be coerced to a character array.

apply(x, 1, cave, c1 = "x1", c2 = c("x1","x2"))

ma <- matrix(c(1:4, 1, 6:8), nrow = 2)
ma
apply(ma, 1, table) #--> a list of length 2
apply(ma, 1, stats::quantile) # 5 x n matrix with rownames

stopifnot(dim(ma) == dim(apply(ma, 1:2, sum)))

## Example with different lengths for each call
z <- array(1:24, dim = 2:4)
zseq <- apply(z, 1:2, function(x) seq_len(max(x)))
zseq ## a 2 x 3 matrix
typeof(zseq) ## list
dim(zseq) ## 2 3
zseq[1,]
apply(z, 3, function(x) seq_len(max(x)))
# a list without a dim attribute
```

args

*Argument List of a Function***Description**

Displays the argument names and corresponding default values of a (non-primitive or primitive) function.

Usage

```
args(name)
```

Arguments

name	a function (a primitive or a closure, i.e., “non-primitive”). If name is a character string then the function with that name is found and used.
------	---

Details

This function is mainly used interactively to print the argument list of a function. For programming, consider using `formals` instead.

Value

For a closure, a closure with identical formal argument list but an empty (NULL) body.

For a primitive (function), a closure with the documented usage and NULL body. Note that some primitives do not make use of named arguments and match by position rather than name. Some primitives, mainly those considered to be language elements, do not have a well-defined argument list; for those NULL is returned.

NULL in case of a non-function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`formals`, `help`; `str` also prints the argument list of a function.

Examples

```
## "regular" (non-primitive) functions "print their arguments"
## (by returning another function with NULL body which you also see):
args(ls)
args(graphics::plot.default)
utils::str(ls) # (just "prints": does not show a NULL)

## You can also pass a string naming a function.
args("scan")
## ...but :: package specification doesn't work in this case.
tryCatch(args("graphics::plot.default"), error = print)
```

```
## As explained above, args() gives a function with empty body:
list(is.f = is.function(args(scan)), body = body(args(scan)))

## Primitive functions mostly behave like non-primitive functions.
args(c)
args(`+`)
## primitive functions without well-defined argument list return NULL:
args(`if`)
```

Arithmetic

Arithmetic Operators

Description

These unary and binary operators perform arithmetic on numeric or complex vectors (or objects which can be coerced to them).

Usage

```
+ x
- x
x + y
x - y
x * y
x / y
x ^ y
x %% y
x %/% y
```

Arguments

x, y	numeric or complex vectors or objects which can be coerced to such, or other objects for which methods have been written.
------	---

Details

The unary and binary arithmetic operators are generic functions: methods can be written for them individually or via the [Ops](#) group generic function. (See [Ops](#) for how dispatch is computed.)

If applied to arrays the result will be an array if this is sensible (for example it will not if the recycling rule has been invoked).

Logical vectors will be coerced to integer or numeric vectors, `FALSE` having value zero and `TRUE` having value one.

$1 \wedge y$ and $y \wedge 0$ are 1, *always*. $x \wedge y$ should also give the proper limit result when either (numeric) argument is [infinite](#) (one of `Inf` or `-Inf`).

Objects such as arrays or time-series can be operated on this way provided they are conformable.

For double arguments, `%%` can be subject to catastrophic loss of accuracy if `x` is much larger than `y`, and a warning is given if this is detected.

`%%` and `x %/% y` can be used for non-integer `y`, e.g. `1 %/% 0.2`, but the results are subject to representation error and so may be platform-dependent. Mathematically, the answer to `1 %/% 0.2`

should be 5, but because the IEC 60559 representation of 0.2 is a binary fraction slightly larger than 0.2 most platforms give 4.

Users are sometimes surprised by the value returned, for example why $(-8)^{(1/3)}$ is NaN. For `double` inputs, R makes use of IEC 60559 arithmetic on all platforms, together with the C system function ‘`pow`’ for the $^$ operator. The relevant standards define the result in many corner cases. In particular, the result in the example above is mandated by the C99 standard. On many Unix-alike systems the command `man pow` gives details of the values in a large number of corner cases.

Arithmetic on type `double` in R is supposed to be done in ‘round to nearest, ties to even’ mode, but this does depend on the compiler and FPU being set up correctly.

Value

Unary $+$ and unary $-$ return a numeric or complex vector. All attributes (including class) are preserved if there is no coercion: logical x is coerced to integer and names, dims and dimnames are preserved.

The binary operators return vectors containing the result of the element by element operations. If involving a zero-length vector the result has length zero. Otherwise, the elements of shorter vectors are recycled as necessary (with a `warning` when they are recycled only *fractionally*). The operators are $+$ for addition, $-$ for subtraction, $*$ for multiplication, $/$ for division and $^$ for exponentiation.

`%%` indicates $x \bmod y$ (“ x modulo y ”), i.e., computes the ‘remainder’ $r <- x \% y$, and `/%` indicates integer division, where R uses “floored” integer division, i.e., $q <- x \%/ y := \text{floor}(x/y)$, as promoted by Donald Knuth, see the Wikipedia page on ‘Modulo operation’, and hence $\text{sign}(r) == \text{sign}(y)$. It is guaranteed that (up to rounding error)

$$x == (x \% y) + y * (x \%/ y)$$

unless $y == 0$ where the result of `%%` is `NA_integer_` or `NaN` (depending on the `typeof` of the arguments) or for some non-*finite* arguments, e.g., when the RHS of the identity above amounts to $\text{Inf} - \text{Inf}$.

If either argument is complex the result will be complex, otherwise if one or both arguments are numeric, the result will be numeric. If both arguments are of type `integer`, the type of the result of $/$ and $^$ is `numeric` and for the other operators it is `integer` (with overflow, which occurs at $\pm(2^{31} - 1)$, returned as `NA_integer_` with a warning).

The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. If the arguments are the same length, attributes will be copied from both, with those of the first argument taking precedence when the same attribute is present in both arguments. For time series, these operations are allowed only if the series are compatible, when the class and `tsp` attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

S4 methods

These operators are members of the S4 `Arith` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops` group generic), with arguments $c(e1, e2)$ (with $e2$ missing for a unary operator).

Implementation limits

R is dependent on OS services (and they on FPU's) for floating-point arithmetic. On all current R platforms IEC 60559 (also known as IEEE 754) arithmetic is used, but some things in those standards are optional. In particular, the support for *denormal* aka *subnormal* numbers (those outside the range given by `.Machine`) may differ between platforms and even between calculations on a single platform.

Another potential issue is signed zeroes: on IEC 60559 platforms there are two zeroes with internal representations differing by sign. Where possible R treats them as the same, but for example direct output from C code often does not do so and may output `'-0.0'` (and on Windows whether it does so or not depends on the version of Windows). One place in R where the difference might be seen is in division by zero: `1/x` is `Inf` or `-Inf` depending on the sign of zero `x`. Another place is `identical(0, -0, num.eq = FALSE)`.

Note

All logical operations involving a zero-length vector have a zero-length result.

The binary operators are sometimes called as functions as e.g. ``&`(x, y)`: see the description of how argument-matching is done in [Ops](#).

`**` is translated in the parser to `^`, but this was undocumented for many years. It appears as an index entry in Becker, Chambers, and Wilks (1988), pointing to the help for `Deprecated` but is not actually mentioned on that page. Even though it had been deprecated in S for 20 years, it was still accepted in R in 2008.

```

array

*Multi-way Arrays***Description**

Creates or tests for arrays.

Usage

```
array(data = NA, dim = length(data), dimnames = NULL)
as.array(x, ...)
is.array(x)
```

Arguments

<code>data</code>	a vector (including a list or expression vector) giving data to fill the array. Non-atomic classed objects are coerced by as.vector .
<code>dim</code>	the <code>dim</code> attribute for the array to be created, that is an integer vector of length one or more giving the maximal indices in each dimension.
<code>dimnames</code>	either <code>NULL</code> or the names for the dimensions. This must be a list (or it will be ignored) with one component for each dimension, either <code>NULL</code> or a character vector of the length given by <code>dim</code> for that dimension. The list can be named, and the list names will be used as names for the dimensions. If the list is shorter than the number of dimensions, it is extended by <code>NULL</code> s to the length required.
<code>x</code>	an R object.
<code>...</code>	additional arguments to be passed to or from methods.

Details

An array in R can have one, two or more dimensions. It is simply a vector which is stored with additional [attributes](#) giving the dimensions (attribute `"dim"`) and optionally names for those dimensions (attribute `"dimnames"`).

A two-dimensional array is the same thing as a [matrix](#).

One-dimensional arrays often look like vectors, but may be handled differently by some functions: [str](#) does distinguish them in recent versions of R.

The `"dim"` attribute is an integer vector of length one or more containing non-negative values: the product of the values must match the length of the array.

The `"dimnames"` attribute is optional: if present it is a list with one component for each dimension, either `NULL` or a character vector of the length given by the element of the `"dim"` attribute for that dimension.

`is.array` is a [primitive](#) function.

For a list array, the `print` method prints entries of length not one in the form `'integer, 7'` indicating the type and length.

Value

`array` returns an array with the extents specified in `dim` and naming information in `dimnames`. The values in `data` are taken to be those in the array with the leftmost subscript moving fastest. If there are too few elements in `data` to fill the array, then the elements in `data` are recycled. If `data` has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

Unlike `matrix`, `array` does not currently remove any attributes left by `as.vector` from a classed list `data`, so can return a list array with a class attribute.

`as.array` is a generic function for coercing to arrays. The default method does so by attaching a `dim` attribute to it. It also attaches `dimnames` if `x` has `names`. The sole purpose of this is to make it possible to access the `dim[names]` attribute at a later time.

`is.array` returns TRUE or FALSE depending on whether its argument is an array (i.e., has a `dim` attribute of positive length) or not. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Note

`is.array` is a [primitive](#) function.

Examples

```
dim(as.array(letters))
array(1:3, c(2,4)) # recycle 1:3 "2 2/3 times"
#      [,1] [,2] [,3] [,4]
# [1,]    1    3    2    1
# [2,]    2    1    3    2
```

array2DF

Convert array to data frame

Description

`array2DF` converts an array, including list arrays commonly returned by `tapply`, into data frames for use in further analysis or plotting functions.

Usage

```
array2DF(x, responseName = "Value",
         sep = "", base = list(LETTERS),
         simplify = TRUE, allowLong = TRUE)
```

Arguments

<code>x</code>	an array object.
<code>responseName</code>	character string, used for creating column name(s) in the result, if required.
<code>sep</code>	character string, used as separator when creating new names, if required.
<code>base</code>	character vector, giving an initial set of names to create <code>dimnames</code> of <code>x</code> , if missing.
<code>simplify</code>	logical, whether to attempt simplification of the result.
<code>allowLong</code>	logical, specifying whether a long format data frame should be returned if <code>x</code> is a list array and all elements of <code>x</code> are unnamed atomic vectors. Ignored unless <code>simplify = TRUE</code> .

Details

The main use of `array2DF` is to convert an array, as typically returned by `tapply`, into a data frame.

When `simplify = FALSE`, this is similar to `as.data.frame.table`, except that it works for list arrays as well as atomic arrays. Specifically, the resulting data frame has one row for each element of the array, with one column for each dimension of the array giving the corresponding `dimnames`. The contents of the array are placed in a column whose name is given by the `responseName` argument. The mode of this column is the same as that of `x`, usually an atomic vector or a list.

If `x` does not have `dimnames`, they are automatically created using `base` and `sep`.

In the default case, when `simplify = TRUE`, some common cases are handled specially.

If all components of `x` are data frames with identical column names (with possibly different numbers of rows), they are `rbind`-ed to form the response. The additional columns giving `dimnames` are repeated according to the number of rows, and `responseName` is ignored in this case.

If all components of `x` are *unnamed* atomic vectors *and* `allowLong = TRUE`, each component is treated as a single-column data frame with column name given by `responseName`, and processed as above.

In all other cases, an attempt to simplify is made by `simplify2array`. If this results in multiple unnamed columns, names are constructed using `responseName` and `sep`.

Value

A data frame with at least `length(dim(x)) + 1` columns. The first `length(dim(x))` columns each represent one dimension of `x` and gives the corresponding values of `dimnames`, which are implicitly created if necessary. The remaining columns contain the contents of `x`, after attempted simplification if requested.

See Also

`tapply`, `as.data.frame.table`, `split`, `aggregate`.

Examples

```
s1 <- with(ToothGrowth,
           tapply(len, list(dose, supp), mean, simplify = TRUE))

s2 <- with(ToothGrowth,
           tapply(len, list(dose, supp), mean, simplify = FALSE))
```

```

str(s1) # atomic array
str(s2) # list array

str(array2DF(s1, simplify = FALSE)) # Value column is vector
str(array2DF(s2, simplify = FALSE)) # Value column is list
str(array2DF(s2, simplify = TRUE))  # simplified to vector

### The remaining examples use the default 'simplify = TRUE'

## List array with list components: columns are lists (no simplification)

with(ToothGrowth,
      tapply(len, list(dose, supp),
              function(x) t.test(x)[c("p.value", "alternative")])) |>
  array2DF() |> str()

## List array with data frame components: columns are atomic (simplified)

with(ToothGrowth,
      tapply(len, list(dose, supp),
              function(x) with(t.test(x), data.frame(p.value, alternative)))) |>
  array2DF() |> str()

## named vectors

with(ToothGrowth,
      tapply(len, list(dose, supp),
              quantile)) |> array2DF()

## unnamed vectors: long format

with(ToothGrowth,
      tapply(len, list(dose, supp),
              sample, size = 5)) |> array2DF()

## unnamed vectors: wide format

with(ToothGrowth,
      tapply(len, list(dose, supp),
              sample, size = 5)) |> array2DF(allowLong = FALSE)

## unnamed vectors of unequal length

with(ToothGrowth[-1, ],
      tapply(len, list(dose, supp),
              sample, replace = TRUE)) |>
  array2DF(allowLong = FALSE)

## unnamed vectors of unequal length with allowLong = TRUE
## (within-group bootstrap)

with(ToothGrowth[-1, ],
      tapply(len, list(dose, supp), sample, replace = TRUE)) |>
  array2DF() |> str()

## data frame input

```

```
tapply(ToothGrowth, ~ dose + supp, FUN = with,
       data.frame(n = length(len), mean = mean(len), sd = sd(len))) |>
array2DF()
```

as.data.frame	<i>Coerce to a Data Frame</i>
---------------	-------------------------------

Description

Functions to check if an object is a data frame, or coerce it if possible.

Usage

```
as.data.frame(x, row.names = NULL, optional = FALSE, ...)

## S3 method for class 'character'
as.data.frame(x, ...,
              stringsAsFactors = FALSE)

## S3 method for class 'list'
as.data.frame(x, row.names = NULL, optional = FALSE, ...,
              cut.names = FALSE, col.names = names(x), fix.empty.names = TRUE,
              new.names = !missing(col.names),
              check.names = !optional,
              stringsAsFactors = FALSE)

## S3 method for class 'matrix'
as.data.frame(x, row.names = NULL, optional = FALSE,
              make.names = TRUE, ...,
              stringsAsFactors = FALSE)

as.data.frame.vector(x, row.names = NULL, optional = FALSE, ...,
                     nm = deparse1(substitute(x)))

is.data.frame(x)
```

Arguments

<code>x</code>	any R object.
<code>row.names</code>	NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
<code>optional</code>	logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names) is optional. Note that all of R's base package <code>as.data.frame()</code> methods use <code>optional</code> only for column names treatment, basically with the meaning of <code>data.frame(*, check.names = !optional)</code> . See also the <code>make.names</code> argument of the <code>matrix</code> method.
<code>...</code>	additional arguments to be passed to or from methods.
<code>stringsAsFactors</code>	logical: should the character vector be converted to a factor?

cut.names	logical or integer; indicating if column names with more than 256 (or cut.names if that is numeric) characters should be shortened (and the last 6 characters replaced by " . . .").
col.names	(optional) character vector of column names.
fix.empty.names	logical indicating if empty column names, i.e., "" should be fixed up (in data.frame) or not.
new.names	logical indicating that col.names should be used (and possibly reset to NA) explicitly.
check.names	logical; passed to the data.frame() call.
make.names	a logical, i.e., one of FALSE, NA, TRUE, indicating what should happen if the row names (of the matrix x) are invalid. If they are invalid, the default, TRUE, calls make.names(*, unique=TRUE); make.names=NA will use “automatic” row names and a FALSE value will signal an error for invalid row names.
nm	a character string to be used as column name.

Details

as.data.frame is a generic function with many methods, and users and packages can supply further methods. For classes that act as vectors, often a copy of as.data.frame.vector will work as the method.

Since R 4.3.0, the *default* method will call as.data.frame.vector for atomic (as by is.atomic) x.

Direct calls of as.data.frame.class are still possible (base package!), for 12 atomic base classes, but are deprecated where calling as.data.frame.vector instead is recommended.

If a list is supplied, each element is converted to a column in the data frame. Similarly, each column of a matrix is converted separately. This can be overridden if the object has a class which has a method for as.data.frame: two examples are matrices of class "model.matrix" (which are included as a single column) and list objects of class "POSIXlt" which are coerced to class "POSIXct".

Arrays can be converted to data frames. One-dimensional arrays are treated like vectors and two-dimensional arrays like matrices. Arrays with more than two dimensions are converted to matrices by ‘flattening’ all dimensions after the first and creating suitable column labels.

Character variables are converted to factor columns unless protected by I.

If a data frame is supplied, all classes preceding "data.frame" are stripped, and the row names are changed if that argument is supplied.

If row.names = NULL, row names are constructed from the names or dimnames of x, otherwise are the integer sequence starting at one. Few of the methods check for duplicated row names. Names are removed from vector columns unless I.

Value

as.data.frame returns a data frame, normally with all row names "" if optional = TRUE.

is.data.frame returns TRUE if its argument is a data frame (that is, has "data.frame" amongst its classes) and FALSE otherwise.

See Also

`data.frame` and `make.names`; `as.data.frame.table` for the `table` method (which has additional arguments).

Examples

```
L0 <- list(LETTERS[1:7], c(4L, 2:3, 5:7, 1L))
L <- L0; names(L) <- nms <- c("nam", "age")
d0 <- as.data.frame(L0, col.names = nms)
(d1 <- as.data.frame(L))
stopifnot(identical(d0, d1))

## showing possibilities on how NA names are handled:
L <- list(A = 1:4); names(L) <- NA
names(dL <- as.data.frame(L)) # "NA."
names(dL1 <- as.data.frame(L, col.names = names(L))) # "NA."
##
names(dL1.<- as.data.frame(L, check.names=FALSE)) # "NA"
##
names(dL2 <- as.data.frame(L, col.names = names(L), check.names=FALSE)) # NA
names(dLn <- as.data.frame(L, new.names = TRUE, check.names=FALSE)) # NA
```

as.Date

Date Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of class "Date" representing calendar dates.

Usage

```
as.Date(x, ...)
## S3 method for class 'character'
as.Date(x, format, tryFormats = c("%Y-%m-%d", "%Y/%m/%d"),
        optional = FALSE, ...)
## S3 method for class 'numeric'
as.Date(x, origin, ...)
## S3 method for class 'POSIXct'
as.Date(x, tz = "UTC", ...)

## S3 method for class 'Date'
format(x, format = "%Y-%m-%d", ...)

## S3 method for class 'Date'
as.character(x, ...)
```

Arguments

<code>x</code>	an object to be converted.
<code>format</code>	a character string. If not specified when converting from a character representation, it will try <code>tryFormats</code> one by one on the first non-NA element, and give an error if none works. Otherwise, the processing is via <code>strptime()</code> whose help page describes available conversion specifications.
<code>tryFormats</code>	character vector of format strings to try if <code>format</code> is not specified.
<code>optional</code>	logical indicating to return NA (instead of signalling an error) if the format guessing does not succeed.
<code>origin</code>	a Date object, or something which can be coerced by <code>as.Date(origin, ...)</code> to such an object or missing . In that case, "1970-01-01" is used.
<code>tz</code>	a time zone name.
<code>...</code>	further arguments to be passed from or to other methods.

Details

The usual vector re-cycling rules are applied to `x` and `format` so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months.

The `as.Date` methods accept character strings, factors, logical NA and objects of classes "[POSIXlt](#)" and "[POSIXct](#)". (The last is converted to days by ignoring the time after midnight in the representation of the time in specified time zone, default UTC.) Also objects of class "date" (from package [date](#)) and "dates" (from package [chron](#)). Character strings are processed as far as necessary for the format specified: any trailing characters are ignored.

`as.Date` will accept numeric data (the number of days since an epoch), since R 4.3.0 also when `origin` is not supplied.

The `format` and `as.character` methods ignore any fractional part of the date.

Value

The `format` and `as.character` methods return a character vector representing the date. NA dates are returned as `NA_character_`.

The `as.Date` methods return an object of class "[Date](#)".

Conversion from other Systems

Most systems record dates internally as the number of days since some origin, but this is fraught with problems, including

- Is the origin day 0 or day 1? As the 'Examples' show, Excel manages to use both choices for its two date systems.
- If the origin is far enough back, the designers may show their ignorance of calendar systems. For example, Excel's designer thought 1900 was a leap year (claiming to copy the error from earlier DOS spreadsheets), and Matlab's designer chose the non-existent date of 'January 0, 0000' (there is no such day), not specifying the calendar. (There is such a year in the 'Gregorian' calendar as used in ISO 8601:2004, but that does say that it is only to be used for years before 1582 with the agreement of the parties in information exchange.)

The only safe procedure is to check the other systems values for known dates: reports on the Internet (including R-help) are more often wrong than right.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-03".

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as 'glibc') are unreliable and guess at the intended meaning.

Years before 1CE (aka 1AD) will probably not be handled correctly.

References

International Organization for Standardization (2004, 1988, 1997, ...) *ISO 8601. Data elements and interchange formats – Information interchange – Representation of dates and times*. For links to versions available on-line see (at the time of writing) <https://www.qsl.net/g1smd/isopdf.htm>.

See Also

[Date](#) for details of the date class; [locales](#) to query or set a locale.

Your system's help pages on `strptime` and `strftime` to see how to specify their formats. Windows users will find no help page for `strptime`: code based on 'glibc' is used (with corrections), so all the format specifiers described here are supported, but with no alternative number representation nor era available in any locale.

Examples

```
## locale-specific version of the date
format(Sys.Date(), "%a %b %d")

## read in date info in format 'ddmmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- as.Date(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
as.Date(dates, "%m/%d/%y")

## date given as number of days since 1900-01-01 (a date in 1989)
as.Date(32768, origin = "1900-01-01")
## Excel is said to use 1900-01-01 as day 1 (Windows default) or
## 1904-01-01 as day 0 (Mac default), but this is complicated by Excel
## incorrectly treating 1900 as a leap year.
## So for dates (post-1901) from Windows Excel
as.Date(35981, origin = "1899-12-30") # 1998-07-05
## and Mac Excel
as.Date(34519, origin = "1904-01-01") # 1998-07-05
## (these values come from http://support.microsoft.com/kb/214330)
```

```
## Experiment shows that Matlab's origin is 719529 days before ours,
## (it takes the non-existent 0000-01-01 as day 1)
## so Matlab day 734373 can be imported as
as.Date(734373) - 719529 # 2010-08-23
## (value from
## http://www.mathworks.de/de/help/matlab/matlab_prog/represent-date-and-times-in-MATLAB.

## Time zone effect
z <- ISOdate(2010, 04, 13, c(0,12)) # midnight and midday UTC
as.Date(z) # in UTC
## these time zone names are common
as.Date(z, tz = "NZ")
as.Date(z, tz = "HST") # Hawaii
```

as.environment

Coerce to an Environment Object

Description

A generic function coercing an R object to an [environment](#). A number or a character string is converted to the corresponding environment on the search path.

Usage

```
as.environment(x)
```

Arguments

x an R object to convert. If it is already an environment, just return it. If it is a positive number, return the environment corresponding to that position on the search list. If it is `-1`, the environment it is called from. If it is a character string, match the string to the names on the search list.

If it is a list, the equivalent of `list2env(x, parent = emptyenv())` is returned.

If `is.object(x)` is true and it has a `class` for which an `as.environment` method is found, that is used.

Details

This is a [primitive](#) generic function: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Value

The corresponding environment object.

Author(s)

John Chambers

See Also

[environment](#) for creation and manipulation, [search](#); [list2env](#).

Examples

```
as.environment(1) ## the global environment
identical(globalenv(), as.environment(1)) ## is TRUE
try( ## <- stats need not be attached
    as.environment("package:stats"))
ee <- as.environment(list(a = "A", b = pi, ch = letters[1:8]))
ls(ee) # names of objects in ee
utils::ls.str(ee)
```

as.function

*Convert Object to Function***Description**

as.function is a generic function which is used to convert objects to functions.

as.function.default works on a list x, which should contain the concatenation of a formal argument list and an expression or an object of mode "call" which will become the function body. The function will be defined in a specified environment, by default that of the caller.

Usage

```
as.function(x, ...)
```

Default S3 method:

```
as.function(x, envir = parent.frame(), ...)
```

Arguments

x	object to convert, a list for the default method.
...	additional arguments to be passed to or from methods.
envir	environment in which the function should be defined.

Value

The desired function.

Author(s)

Peter Dalgaard

See Also

[function](#); [alist](#) which is handy for the construction of argument lists, etc.

Examples

```
as.function(alist(a = , b = 2, a+b))
as.function(alist(a = , b = 2, a+b))(3)
```

Description

Functions to manipulate objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```
as.POSIXct(x, tz = "", ...)
as.POSIXlt(x, tz = "", ...)

## S3 method for class 'character'
as.POSIXlt(x, tz = "", format,
            tryFormats = c("%Y-%m-%d %H:%M:%OS",
                           "%Y/%m/%d %H:%M:%OS",
                           "%Y-%m-%d %H:%M",
                           "%Y/%m/%d %H:%M",
                           "%Y-%m-%d",
                           "%Y/%m/%d"),
            optional = FALSE, ...)
## Default S3 method:
as.POSIXlt(x, tz = "",
            optional = FALSE, ...)
## S3 method for class 'numeric'
as.POSIXlt(x, tz = "", origin, ...)

## S3 method for class 'Date'
as.POSIXct(x, tz = "UTC", ...)
## S3 method for class 'Date'
as.POSIXlt(x, tz = "UTC", ...)
## S3 method for class 'numeric'
as.POSIXct(x, tz = "", origin, ...)

## S3 method for class 'POSIXlt'
as.double(x, ...)
```

Arguments

x	R object to be converted.
tz	a character string. The time zone specification to be used for the conversion, <i>if one is required</i> . System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). Invalid values are most commonly treated as UTC, on some platforms with a warning.
...	further arguments to be passed to or from other methods.
format	character string giving a date-time format as used by strptime .
tryFormats	character vector of format strings to try if format is not specified.
optional	logical indicating to return NA (instead of signalling an error) if the format guessing does not succeed.

`origin` a date-time object, or something which can be coerced by `as.POSIXct(tz = "GMT")` to such an object. Optional since R 4.3.0, where the equivalent of "1970-01-01" is used.

Details

The `as.POSIX*` functions convert an object to one of the two classes used to represent date/times (calendar dates plus time to the nearest second). They can convert objects of the other class and of class `"Date"` to these classes. Dates without times are treated as being at midnight UTC.

They can also convert character strings of the formats `"2001-02-03"` and `"2001/02/03"` optionally followed by white space and a time in the format `"14:52"` or `"14:52:03"`. (Formats such as `"01/02/03"` are ambiguous but can be converted via a format specification by `strptime`.) Fractional seconds are allowed. Alternatively, `format` can be specified for character vectors or factors: if it is not specified and no standard format works for all non-NA inputs an error is thrown.

If `format` is specified, remember that some of the format specifications are locale-specific, and you may need to set the `LC_TIME` category appropriately via `Sys.setlocale`. This most often affects the use of `%a`, `%A` (weekday names), `%b`, `%B` (month names) and `%p` (AM/PM).

Logical NAs can be converted to either of the classes, but no other logical vectors can be.

If you are given a numeric time as the number of seconds since an epoch, see the examples.

Character input is first converted to class `"POSIXlt"` by `strptime`: numeric input is first converted to `"POSIXct"`. Any conversion that needs to go between the two date-time classes requires a time zone: conversion from `"POSIXlt"` to `"POSIXct"` will validate times in the selected time zone. One issue is what happens at transitions to and from DST, for example in the UK

```
as.POSIXct(strptime("2011-03-27 01:30:00", "%Y-%m-%d %H:%M:%S"))
as.POSIXct(strptime("2010-10-31 01:30:00", "%Y-%m-%d %H:%M:%S"))
```

are respectively invalid (the clocks went forward at 1:00 GMT to 2:00 BST) and ambiguous (the clocks went back at 2:00 BST to 1:00 GMT). What happens in such cases is OS-specific: one should expect the first to be NA, but the second could be interpreted as either BST or GMT (and common OSes give both possible values). Note too (see `strftime`) that OS facilities may not format invalid times correctly.

Value

`as.POSIXct` and `as.POSIXlt` return an object of the appropriate class, see `POSIXt` and its ‘Warnings’ section on too narrow assumptions.

If `tz` was specified, `as.POSIXlt` will give an appropriate `"tzone"` attribute. Date-times known to be invalid will be returned as NA.

Note

Some of the concepts used have to be extended backwards in time (the usage is said to be ‘proleptic’). For example, the origin of time for the `"POSIXct"` class, ‘1970-01-01 00:00.00 UTC’, is before UTC was defined. More importantly, conversion is done assuming the Gregorian calendar which was introduced in 1582 and not used near-universally until the 20th century. One of the re-interpretations assumed by ISO 8601:2004 is that there was a year zero, even though current year numbering (and zero) is a much later concept (525 CE for year numbers from 1 CE).

Conversions between `"POSIXlt"` and `"POSIXct"` of future times are speculative except in UTC. The main uncertainty is in the use of and transitions to/from DST (most systems will assume the continuation of current rules but these can be changed at short notice).

If you want to extract specific aspects of a time (such as the day of the week) just convert it to class "POSIXlt" and extract the relevant component(s) of the list, or if you want a character representation (such as a named day of the week) use the [format](#) method.

If a time zone is needed and that specified is invalid on your system, what happens is system-specific but attempts to set it will probably be ignored.

Conversion from character needs to find a suitable format unless one is supplied (by trying common formats in turn): this can be slow for long inputs.

See Also

[DateTimeClasses](#) for details of the classes; [strptime](#) for conversion to and from character representations.

[Sys.timezone](#) for details of the (system-specific) naming of time zones.

[locales](#) for locale-specific aspects.

Examples

```
(z <- Sys.time())           # the current datetime, as class "POSIXct"
unclass(z)                  # a large integer
floor(unclass(z)/86400)     # the number of days since 1970-01-01 (UTC)
(now <- as.POSIXlt(Sys.time())) # the current datetime, as class "POSIXlt"
str(unclass(now))           # the internal list ; use now$hour, etc :
now$year + 1900             # see ?DateTimeClasses
months(now); weekdays(now) # see ?months; using LC_TIME locale

## suppose we have a time in seconds since 1960-01-01 00:00:00 GMT
## (the origin used by SAS)
z <- 1472562988
# ways to convert this
as.POSIXct(z, origin = "1960-01-01")           # local
as.POSIXct(z, origin = "1960-01-01", tz = "GMT") # in UTC

## SPSS dates (R-help 2006-02-16)
z <- c(10485849600, 10477641600, 10561104000, 10562745600)
as.Date(as.POSIXct(z, origin = "1582-10-14", tz = "GMT"))

## Stata date-times: milliseconds since 1960-01-01 00:00:00 GMT
## format %tc excludes leap-seconds, assumed here
## For format %tC including leap seconds, see foreign::read.dta()
z <- 1579598122120
op <- options(digits.secs = 3)
# avoid rounding down: milliseconds are not exactly representable
as.POSIXct((z+0.1)/1000, origin = "1960-01-01")
options(op)

## Matlab 'serial day number' (days and fractional days)
z <- 7.343736909722223e5 # 2010-08-23 16:35:00
as.POSIXct((z - 719529)*86400, origin = "1970-01-01", tz = "UTC")

as.POSIXlt(Sys.time(), "GMT") # the current time in UTC

## These may not be correct names on your system
as.POSIXlt(Sys.time(), "America/New_York") # in New York
as.POSIXlt(Sys.time(), "EST5EDT")         # alternative.
as.POSIXlt(Sys.time(), "EST" )            # somewhere in Eastern Canada
```

```

  cols <- c("code", "coordinates", "TZ", "comments")
  tmp <- read.delim(tab,
                    header = FALSE, comment.char = "#", col.names = cols)
  if(interactive()) View(tmp)
  head(tmp, 10)
}

```

AsIs

*Inhibit Interpretation/Conversion of Objects***Description**

Change the class of an object to indicate that it should be treated ‘as is’.

Usage

```
I(x)
```

Arguments

`x` an object

Details

Function `I` has two main uses.

- In function `data.frame`. Protecting an object by enclosing it in `I()` in a call to `data.frame` inhibits the conversion of character vectors to factors (only relevant if `stringsAsFactors = TRUE`) and the dropping of names, and ensures that matrices are inserted as single columns. `I` can also be used to protect objects which are to be added to a data frame, or converted to a data frame *via* `as.data.frame`. It achieves this by prepending the class `"AsIs"` to the object’s classes. Class `"AsIs"` has a few of its own methods, including `for`, `as.data.frame`, `print` and `format`.
- In function `formula`. There it is used to inhibit the interpretation of operators such as `"+"`, `"-"`, `"*"` and `"^"` as formula operators, so they are used as arithmetical operators. This is interpreted as a symbol by `terms.formula`.

Value

A copy of the object with class `"AsIs"` prepended to the class(es).

asplit

Split Array/Matrix By Its Margins

Description

Split an array or matrix by its margins.

Usage

```
asplit(x, MARGIN, drop = FALSE)
```

Arguments

x	an array, including a matrix.
MARGIN	a vector giving the margins to split by. E.g., for a matrix 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns. Where x has named dimnames, it can be a character vector selecting dimension names.
drop	a logical indicating whether the splits should drop dimensions and dimnames.

Details

Since R 4.1.0, one can also obtain the splits (less efficiently) using `apply(x, MARGIN, identity, simplify = FALSE)`. The values of the splits can also be obtained (less efficiently) by `split(x, slice.index(x, MARGIN))`.

Value

A “list array” with dimension *dv* and each element an array of dimension *de* and dimnames preserved as available if `drop` is false and a vector otherwise, where *dv* and *de* are, respectively, the dimensions of *x* included and not included in *MARGIN*.

Examples

```
## A 3-dimensional array of dimension 2 x 3 x 4:
d <- 2 : 4
x <- array(seq_len(prod(d)), d)
x
## Splitting by margin 2 gives a 1-d list array of length 3
## consisting of 2 x 4 arrays:
asplit(x, 2)
## Splitting by margins 1 and 2 gives a 2 x 3 list array
## consisting of 1-d arrays of length 4:
asplit(x, c(1, 2))
## Compare to
split(x, slice.index(x, c(1, 2)))

## A 2 x 3 matrix:
(x <- matrix(1 : 6, 2, 3))
## To split x by its rows, one can use
```

```

asplit(x, 1)
## or less efficiently
split(x, slice.index(x, 1))
split(x, row(x))

```

assign

Assign a Value to a Name

Description

Assign a value to a name in an environment.

Usage

```

assign(x, value, pos = -1, envir = as.environment(pos),
       inherits = FALSE, immediate = TRUE)

```

Arguments

<code>x</code>	a variable name, given as a character string. No coercion is done, and the first element of a character vector of length greater than one will be used, with a warning.
<code>value</code>	a value to be assigned to <code>x</code> .
<code>pos</code>	where to do the assignment. By default, assigns into the current environment. See ‘Details’ for other possibilities.
<code>envir</code>	the environment to use. See ‘Details’.
<code>inherits</code>	should the enclosing frames of the environment be inspected?
<code>immediate</code>	an ignored compatibility feature.

Details

There are no restrictions on the name given as `x`: it can be a non-syntactic name (see [make.names](#)).

The `pos` argument can specify the environment in which to assign the object in any of several ways: as `-1` (the default), as a positive integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using [sys.frame](#) to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily for back compatibility.

`assign` does not dispatch assignment methods, so it cannot be used to set elements of vectors, names, attributes, etc.

Note that assignment to an attached list or data frame changes the attached copy and not the original object: see [attach](#) and [with](#).

Value

This function is invoked for its side effect, which is assigning `value` to the variable `x`. If no `envir` is specified, then the assignment takes place in the currently active environment.

If `inherits` is `TRUE`, enclosing environments of the supplied environment are searched until the variable `x` is encountered. The value is then assigned in the environment in which the variable is encountered (provided that the binding is not locked: see [lockBinding](#): if it is, an error is signaled). If the symbol is not encountered then assignment takes place in the user's workspace (the global environment).

If `inherits` is `FALSE`, assignment takes place in the initial frame of `envir`, unless an existing binding is locked or there is no existing binding and the environment is locked (when an error is signaled).

See Also

[<-](#), [get](#), the inverse of [assign\(\)](#), [exists](#), [environment](#).

Examples

```
for(i in 1:6) { #-- Create objects 'r.1', 'r.2', ... 'r.6' --
  nam <- paste("r", i, sep = ".")
  assign(nam, 1:i)
}
ls(pattern = "^r..$")

##-- Global assignment within a function:
myf <- function(x) {
  innerf <- function(x) assign("Global.res", x^2, envir = .GlobalEnv)
  innerf(x+1)
}
myf(3)
Global.res # 16

a <- 1:4
assign("a[1]", 2)
a[1] == 2      # FALSE
get("a[1]") == 2 # TRUE
```

Description

Assign a value to a name.

Usage

```
x <- value
x <<- value
value -> x
value ->> x

x = value
```

Arguments

<code>x</code>	a variable name (possibly quoted).
<code>value</code>	a value to be assigned to <code>x</code> .

Details

There are three different assignment operators: two of them have leftwards and rightwards forms.

The operators `<-` and `=` assign into the environment in which they are evaluated. The operator `<-` can be used anywhere, whereas the operator `=` is only allowed at the top level (e.g., in the complete expression typed at the command prompt) or as one of the subexpressions in a braced list of expressions.

The operators `<<-` and `->>` are normally only used in functions, and cause a search to be made through parent environments for an existing definition of the variable being assigned. If such a variable is found (and its binding is not locked) then its value is redefined, otherwise assignment takes place in the global environment. Note that their semantics differ from that in the S language, but are useful in conjunction with the scoping rules of R. See *The R Language Definition* for further details and examples.

In all the assignment operator expressions, `x` can be a name or an expression defining a part of an object to be replaced (e.g., `z[[1]]`). A syntactic name does not need to be quoted, though it can be (preferably by [backticks](#)).

The leftwards forms of assignment `<-` = `<<-` group right to left, the other from left to right.

Value

value. Thus one can use `a <- b <- c <- 6`.

attach

Attach Set of R Objects to Search Path

Description

The database is attached to the R search path. This means that the database is searched by R when evaluating a variable, so objects in the database can be accessed by simply giving their names.

Usage

```
attach(what, pos = 2L, name = deparse1(substitute(what), backtick=FALSE),
       warn.conflicts = TRUE)
```

Arguments

what	'database'. This can be a <code>data.frame</code> or a <code>list</code> or a R data file created with <code>save</code> or <code>NULL</code> or an environment. See also 'Details'.
pos	integer specifying position in <code>search()</code> where to attach.
name	name to use for the attached database. Names starting with <code>package:</code> are reserved for <code>library</code> .
warn.conflicts	logical. If <code>TRUE</code> , <code>message()</code> s are printed about <code>conflicts</code> from attaching the database, unless that database contains an object <code>.conflicts.OK</code> . A conflict is a function masking a function, or a non-function masking a non-function. NB: Even though the name is <code>warn.conflicts</code> for historical reasons, the messages about conflicts are <i>not</i> <code>warning()</code> s but <code>message()</code> s.

Details

When evaluating a variable or function name R searches for that name in the databases listed by `search`. The first name of the appropriate type is used.

By attaching a data frame (or list) to the search path it is possible to refer to the variables in the data frame by their names alone, rather than as components of the data frame (e.g., in the example below, `height` rather than `women$height`).

By default the database is attached in position 2 in the search path, immediately after the user's workspace and before all previously attached packages and previously attached databases. This can be altered to attach later in the search path with the `pos` option, but you cannot attach at `pos = 1`.

The database is not actually attached. Rather, a new environment is created on the search path and the elements of a list (including columns of a data frame) or objects in a save file or an environment are *copied* into the new environment. If you use `<-` or `assign` to assign to an attached database, you only alter the attached copy, not the original object. (Normal assignment will place a modified version in the user's workspace: see the examples.) For this reason `attach` can lead to confusion.

One useful 'trick' is to use `what = NULL` (or equivalently a length-zero list) to create a new environment on the search path into which objects can be assigned by `assign` or `load` or `sys.source`.

Names starting "package:" are reserved for `library` and should not be used by end users. Attached files are by default given the name `file:what`. The `name` argument given for the attached environment will be used by `search` and can be used as the argument to `as.environment`.

Value

The `environment` is returned invisibly with a "name" attribute.

Good practice

`attach` has the side effect of altering the search path and this can easily lead to the wrong object of a particular name being found. People do often forget to `detach` databases.

In interactive use, `with` is usually preferable to the use of `attach/detach`, unless what is a `save()`-produced file in which case `attach()` is a (safety) wrapper for `load()`.

In programming, functions should not change the search path unless that is their purpose. Often `with` can be used within a function. If not, good practice is to

- Always use a distinctive name argument, and
- To immediately follow the `attach` call by an `on.exit` call to `detach` using the distinctive name.

This ensures that the search path is left unchanged even if the function is interrupted or if code after the `attach` call changes the search path.

`library`, `detach`, `search`, `objects`, `environment`, `with`.

Examples

```
require(utils)

summary(women$height)      # refers to variable 'height' in the data frame
attach(women)
summary(height)            # The same variable now available by name
height <- height*2.54      # Don't do this. It creates a new variable
                           # in the user's workspace

find("height")
summary(height)            # The new variable in the workspace
rm(height)
summary(height)            # The original variable.
height <- height*25.4      # Change the copy in the attached environment
find("height")
summary(height)            # The changed copy
detach("women")
summary(women$height)      # unchanged

## Not run: ## create an environment on the search path and populate it
sys.source("myfuns.R", envir = attach(NULL, name = "myfuns"))

## End(Not run)
```

attr

*Object Attributes***Description**

Get or set specific attributes of an object.

Usage

```
attr(x, which, exact = FALSE)
attr(x, which) <- value
```

Arguments

<code>x</code>	an object whose attributes are to be accessed.
<code>which</code>	a non-empty character string specifying which attribute is to be accessed.
<code>exact</code>	logical: should <code>which</code> be matched exactly?
<code>value</code>	an object, the new value of the attribute, or <code>NULL</code> to remove the attribute.

Details

These functions provide access to a single attribute of an object. The replacement form causes the named attribute to take the value specified (or create a new attribute with the value given), unless the object is `NULL`, a `symbol` (aka ‘name’) or a `primitive` function.

The extraction function first looks for an exact match to `which` amongst the attributes of `x`, then (unless `exact = TRUE`) a unique partial match. (Setting `options(warnPartialMatchAttr = TRUE)` causes partial matches to give warnings.)

The replacement function only uses exact matches.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

The extractor function allows (and does not match) empty and missing values of `which`: the replacement function does not.

`NULL` objects cannot have attributes and attempting to assign one by `attr` gives an error.

Both are `primitive` functions.

Value

For the extractor, the value of the attribute matched, or `NULL` if no exact match is found and no or more than one partial match is found.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`attributes`

Examples

```
# create a 2 by 5 matrix
x <- 1:10
attr(x, "dim") <- c(2, 5)

S <- sum
try( attr(S, "foo") <- NA ) # no longer possible to mutate primitive functions
```

attributes

Object Attribute Lists

Description

These functions access an object's attributes. The first form below returns the object's attribute list. The replacement forms uses the list on the right-hand side of the assignment as the object's attributes (if appropriate).

Usage

```
attributes(x)
attributes(x) <- value
mostattributes(x) <- value
```

Arguments

<code>x</code>	any R object; for the replacement functions, not a symbol (aka 'name') nor a primitive function.
<code>value</code>	an appropriate named list of attributes, or NULL.

Details

Unlike [attr](#) it is currently not an error to set attributes on a NULL object: it will first be coerced to an empty [list](#).

Note that some attributes (namely [class](#), [comment](#), [dim](#), [dimnames](#), [names](#), [row.names](#) and [tsp](#)) are treated specially and have restrictions on the values which can be set. (Note that this is not true of [levels](#) which should be set for factors via the [levels](#) replacement function.)

Attributes are not stored internally as a list and should be thought of as a set and not a vector, i.e. the *order* of the elements of [attributes\(\)](#) does not matter. This is also reflected by [identical\(\)](#)'s behaviour with the default argument `attrib.as.set = TRUE`. Attributes must have unique names (and NA is taken as "NA", not a missing value).

Assigning attributes first removes all attributes, then sets any `dim` attribute and then the remaining attributes in the order given: this ensures that setting a `dim` attribute always precedes the `dimnames` attribute.

The `mostattributes` assignment takes special care for the [dim](#), [names](#) and [dimnames](#) attributes, and assigns them only when known to be valid whereas an `attributes` assignment would give an error if any are not. It is principally intended for arrays, and should be used with care on classed objects. For example, it does not check that [row.names](#) are assigned correctly for data frames.

The names of a pairlist are not stored as attributes, but are reported as if they were (and can be set by the replacement form of [attributes](#)).

`NULL` objects cannot have attributes and attempts to assign them will promote the object to an empty list.

Both assignment and replacement forms of `attributes` are [primitive](#) functions.

[attr](#), [structure](#).

Examples

```
x <- cbind(a = 1:3, pi = pi) # simple matrix with dimnames
attributes(x)

## strip an object's attributes:
attributes(x) <- NULL
x # now just a vector of length 6

mostattributes(x) <- list(mycomment = "really special", dim = 3:2,
  dimnames = list(LETTERS[1:3], letters[1:5]), names = paste(1:6))
x # dim(), but not {dim}names
```

autoload

On-demand Loading of Packages

Description

`autoload` creates a promise-to-evaluate autoloader and stores it with name `name` in `.AutoloadEnv` environment. When R attempts to evaluate `name`, `autoloader` is run, the package is loaded and `name` is re-evaluated in the new package's environment. The result is that R behaves as if package was loaded but it does not occupy memory.

`.Autoloaded` contains the names of the packages for which autoloading has been promised.

Usage

```
autoload(name, package, reset = FALSE, ...)
autoloader(name, package, ...)

.AutoloadEnv
.Autoloaded
```

Arguments

<code>name</code>	string giving the name of an object.
<code>package</code>	string giving the name of a package containing the object.
<code>reset</code>	logical: for internal use by <code>autoloader</code> .
<code>...</code>	other arguments to library .

Value

This function is invoked for its side-effect. It has no return value.

See Also

`delayedAssign`, `library`

Examples

```
require(stats)
autoload("interpSpline", "splines")
search()
ls("Autoloads")
.Autoloaded

x <- sort(stats::rnorm(12))
y <- x^2
is <- interpSpline(x, y)
search() ## now has splines
detach("package:splines")
search()
is2 <- interpSpline(x, y+x)
search() ## and again
detach("package:splines")
```

backsolve

Solve an Upper or Lower Triangular System

Description

Solves a triangular system of linear equations.

Usage

```
backsolve(r, x, k = ncol(r), upper.tri = TRUE,
          transpose = FALSE)
forwardsolve(l, x, k = ncol(l), upper.tri = FALSE,
             transpose = FALSE)
```

Arguments

<code>r, l</code>	an upper (or lower) triangular matrix giving the coefficients for the system to be solved. Values below (above) the diagonal are ignored.
<code>x</code>	a matrix whose columns give the right-hand sides for the equations.
<code>k</code>	the number of columns of <code>r</code> and rows of <code>x</code> to use.
<code>upper.tri</code>	logical; if <code>TRUE</code> (default), the <i>upper triangular</i> part of <code>r</code> is used. Otherwise, the lower one.
<code>transpose</code>	logical; if <code>TRUE</code> , solve $r' * y = x$ for y , i.e., <code>t(r) %*% y == x</code> .

Details

Solves a system of linear equations where the coefficient matrix is upper (or ‘right’, ‘R’) or lower (‘left’, ‘L’) triangular.

`x <- backsolve (R, b)` solves $Rx = b$, and
`x <- forwardsolve (L, b)` solves $Lx = b$, respectively.

The `r/l` must have at least `k` rows and columns, and `x` must have at least `k` rows.

This is a wrapper for the level-3 BLAS routine `dtrsm`.

Value

The solution of the triangular system. The result will be a vector if `x` is a vector and a matrix if `x` is a matrix.

Examples

```
## upper triangular matrix 'r':
r <- rbind(c(1,2,3),
           c(0,1,1),
           c(0,0,2))
( y <- backsolve(r, x <- c(8,4,2)) ) # -1 3 1
r %*% y # == x = (8,4,2)
backsolve(r, x, transpose = TRUE) # 8 -12 -5
```

balancePOSIXlt

Balancing “Ragged” and Out-of-range POSIXlt Date-Times

Description

Utilities to ‘balance’ objects of class “POSIXlt”.

`unCfillPOSIXlt(x)` is a fast **primitive** version of `balancePOSIXlt(x, fill.only=TRUE, classed=FALSE)` or equivalently, `unclass(balancePOSIXlt(x, fill.only=TRUE))` from where it is named.

Usage

```
balancePOSIXlt(x, fill.only = FALSE, classed = TRUE)
unCfillPOSIXlt(x)
```

Arguments

<code>x</code>	an R object inheriting from "POSIXlt", see POSIXlt .
<code>fill.only</code>	a logical specifying if <code>balancePOSIXlt(x, ...)</code> should only “fill up” by recycling, but not re-check validity nor recompute, e.g., <code>x\$yday</code> and <code>x\$yday</code> .
<code>classed</code>	a logical specifying if the result should be classed, true by default. Using <code>balancePOSIXlt(x, classed = FALSE)</code> is equivalent to but faster than <code>unclass(balancePOSIXlt(x))</code> .

“Ragged” and Out-of-range vs “Balanced” POSIXlt

Note that "POSIXlt" objects `x` may have their (9 to 11) list components of different [lengths](#), by simply recycling them to full length. Prior to R 4.3.0, this has worked in printing, formatting, and conversion to "POSIXct", but often not for `length()`, conversion to "Date" or indexing, i.e., subsetting, `[`, or subassigning, `[<-`.

Relatedly, components `sec`, `min`, `hour`, `mday` and `mon` could have been out of their designated range (say, 0–23 for hours) and still work correctly, e.g. in conversions and printing. This is supported as well, since R 4.3.0, at least when the values are not extreme.

Function `balancePOSIXlt(x)` will now return a version of the "POSIXlt" object `x` which by default is balanced in both ways: All the internal list components are of full length, and their values are inside their ranges as specified in [as.POSIXlt](#)’s ‘Details on POSIXlt’. Setting `fill.only = TRUE` will only recycle the list components to full length, but not check them at all. This is particularly faster when all components of `x` are already of full length.

Experimentally, `balancePOSIXlt()` and other functions returning POSIXlt objects now set a [logical](#) attribute "balanced" with NA meaning “filled-in”, i.e., not “ragged” and TRUE means (fully) balanced.

See Also

For more details about many aspects of valid POSIXlt objects, notably their internal list components, see ‘[DateTimeClasses](#)’, e.g., [as.POSIXlt](#), notably the section ‘Details on POSIXlt’.

Examples

```
## FIXME: this should also work for regular (non-UTC) time zones.
TZ <- "UTC"
# Could be
# d1 <- as.POSIXlt("2000-01-02 3:45", tz = TZ)
# on systems (almost all) which have tm_zone.
oldTZ <- Sys.getenv('TZ', unset = "unset")
Sys.setenv(TZ = "UTC")
d1 <- as.POSIXlt("2000-01-02 3:45")
d1$min <- d1$min + (0:16)*20L
(f1 <- format(d1))
str(unclass(d1))      # only $min is of length > 1
df <- balancePOSIXlt(d1, fill.only = TRUE) # a "POSIXlt" object
str(unclass(df))      # all of length 17; 'min' unchanged
db <- balancePOSIXlt(d1, classed = FALSE) # a list
stopifnot(identical(
  unCfillPOSIXlt(d1),
  balancePOSIXlt(d1, fill.only = TRUE, classed = FALSE)))
str(db) # of length 17 *and* in range
```

```
if(oldTZ == "unset") Sys.unsetenv('TZ') else Sys.setenv(TZ = oldTZ)
```

basename	<i>Manipulate File Paths</i>
----------	------------------------------

Description

`basename` removes all of the path up to and including the last path separator (if any).

`dirname` returns the part of the path up to but excluding the last path separator, or "." if there is no path separator.

Usage

```
basename(path)
dirname(path)
```

Arguments

`path` character vector, containing path names.

Details

[tilde expansion](#) of the path will be performed.

Trailing path separators are removed before dissecting the path, and for `dirname` any trailing file separators are removed from the result.

Value

A character vector of the same length as `path`. A zero-length input will give a zero-length output with no error.

Paths not containing any separators are taken to be in the current directory, so `dirname` returns ".".

If an element of `path` is [NA](#), so is the result.

"" is not a valid pathname, but is returned unchanged.

Behaviour on Windows

On Windows this will accept either \ or / as the path separator, but `dirname` will return a path using / (except if on a network share, when the leading \\ will be preserved). Expect these only to be able to handle complete paths, and not for example just a network share or a drive.

UTF-8-encoded path names not valid in the current locale can be used.

Note

These are not wrappers for the POSIX system functions of the same names: in particular they do **not** have the special handling of the path "/" and of returning "." for empty strings.

See Also

[file.path](#), [path.expand](#).

Examples

```
basename(file.path("", "p1", "p2", "p3", c("file1", "file2")))
dirname (file.path("", "p1", "p2", "p3", "filename"))
```

Bessel

*Bessel Functions***Description**

Bessel Functions of integer and fractional order, of first and second kind, J_ν and Y_ν , and Modified Bessel functions (of first and third kind), I_ν and K_ν .

Usage

```
besselI(x, nu, expon.scaled = FALSE)
besselK(x, nu, expon.scaled = FALSE)
besselJ(x, nu)
besselY(x, nu)
```

Arguments

<code>x</code>	numeric, ≥ 0 .
<code>nu</code>	numeric; the <i>order</i> (maybe fractional and negative) of the corresponding Bessel function.
<code>expon.scaled</code>	logical; if TRUE, the results are exponentially scaled in order to avoid overflow (I_ν) or underflow (K_ν), respectively.

Details

If `expon.scaled = TRUE`, $e^{-x}I_\nu(x)$, or $e^xK_\nu(x)$ are returned.

For $\nu < 0$, formulae 9.1.2 and 9.6.2 from Abramowitz and Stegun (1972) are applied (which is probably suboptimal), except for `besselK` which is symmetric in `nu`.

The current algorithms will give warnings about accuracy loss for large arguments. In some cases, these warnings are exaggerated, and the precision is perfect. For large `nu`, say in the order of millions, the current algorithms are rarely useful.

Value

Numeric vector with the (scaled, if `expon.scaled = TRUE`) values of the corresponding Bessel function.

The length of the result is the maximum of the lengths of the parameters. All parameters are recycled to that length.

Author(s)

Original Fortran code: W. J. Cody, Argonne National Laboratory

Translation to C and adaptation to R: Martin Maechler <maechler@stat.math.ethz.ch>.

Source

The C code is a translation of Fortran routines from <https://netlib.org/specfun/ribesl>, ‘`../rjbesl`’, etc. The four source code files for `bessel[IJKY]` each contain a paragraph “Acknowledgement” and “References”, a short summary of which is

`besselI` based on (code by) David J. Sookne, see Sookne (1973) ... Modifications ... An earlier version was published in Cody (1983).

`besselJ` as `besselI`

`besselK` based on (code by) Campbell (1980) ... Modifications ...

`besselY` draws heavily on Temme’s Algol program for Y_{ν} ...and on Campbell’s programs for $Y_{\nu}(x)$ heavily modified.

bindenv

Binding and Environment Locking, Active Bindings

Description

These functions represent an interface for adjustments to environments and bindings within environments. They allow for locking environments as well as individual bindings, and for linking a variable to a function.

Usage

```

lockEnvironment(env, bindings = FALSE)
environmentIsLocked(env)
lockBinding(sym, env)
unlockBinding(sym, env)
bindingIsLocked(sym, env)

makeActiveBinding(sym, fun, env)
bindingIsActive(sym, env)
activeBindingFunction(sym, env)

```

Arguments

<code>env</code>	an environment.
<code>bindings</code>	logical specifying whether bindings should be locked.
<code>sym</code>	a name object or character string.
<code>fun</code>	a function taking zero or one arguments.

Details

The function `lockEnvironment` locks its environment argument. Locking the environment prevents adding or removing variable bindings from the environment. Changing the value of a variable is still possible unless the binding has been locked. The namespace environments of packages with namespaces are locked when loaded.

`lockBinding` locks individual bindings in the specified environment. The value of a locked binding cannot be changed. Locked bindings may be removed from an environment unless the environment is locked.

`makeActiveBinding` installs `fun` in environment `env` so that getting the value of `sym` calls `fun` with no arguments, and assigning to `sym` calls `fun` with one argument, the value to be assigned. This allows the implementation of things like C variables linked to R variables and variables linked to databases, and is used to implement `setRefClass`. It may also be useful for making thread-safe versions of some system globals. Currently active bindings are not preserved during package installation, but they can be created in `.onLoad`.

Value

The `bindingIsLocked` and `environmentIsLocked` return a length-one logical vector. The remaining functions return `NULL`, invisibly.

Author(s)

Luke Tierney

Examples

```
# locking environments
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockEnvironment(e)
get("x", envir = e)
assign("x", 2, envir = e)
try(assign("y", 2, envir = e)) # error

# locking bindings
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockBinding("x", e)
try(assign("x", 2, envir = e)) # error
unlockBinding("x", e)
assign("x", 2, envir = e)
get("x", envir = e)

# active bindings
f <- local( {
  x <- 1
  function(v) {
    if (missing(v))
      cat("get\n")
    else {
      cat("set\n")
      x <- v
    }
  }
  x
})
makeActiveBinding("fred", f, .GlobalEnv)
bindingIsActive("fred", .GlobalEnv)
fred
fred <- 2
fred
```

Description

Logical operations on integer vectors with elements viewed as sets of bits.

Usage

```
bitwNot(a)
bitwAnd(a, b)
bitwOr(a, b)
bitwXor(a, b)

bitwShiftL(a, n)
bitwShiftR(a, n)
```

Arguments

`a, b` integer vectors; numeric vectors are coerced to integer vectors.

`n` non-negative integer vector of values up to 31.

Details

Each element of an integer vector has 32 bits.

Pairwise operations can result in integer NA.

Shifting is done assuming the values represent unsigned integers.

Value

An integer vector of length the longer of the arguments, or zero length if one is zero-length.

The output element is NA if an input is NA (after coercion) or an invalid shift.

See Also

The logical operators, `!`, `&`, `|`, `xor`. Notably these *do* work bitwise for `raw` arguments.

The classes `"octmode"` and `"hexmode"` whose implementation of the standard logical operators is based on these functions.

Package **bitops** has similar functions for numeric vectors which differ in the way they treat integers 2^{31} or larger.

Examples

```
bitwNot(0:12) # -1 -2 ... -13
bitwAnd(15L, 7L) # 7
bitwOr(15L, 7L) # 15
bitwXor(15L, 7L) # 8
bitwXor(-1L, 1L) # -2

## The "same" for 'raw' instead of integer :
rr12 <- as.raw(0:12) ; rbind(rr12, !rr12)
c(r15 <- as.raw(15), r7 <- as.raw(7)) # 0f 07
r15 & r7 # 07
r15 | r7 # 0f
xor(r15, r7) # 08

bitwShiftR(-1, 1:31) # shifts of 2^32-1 = 4294967295
```

body

*Access to and Manipulation of the Body of a Function***Description**

Get or set the *body* of a function which is basically all of the function definition but its formal arguments ([formals](#)), see the ‘Details’.

Usage

```
body(fun = sys.function(sys.parent()))
body(fun, envir = environment(fun)) <- value
```

Arguments

<code>fun</code>	a function object, or see ‘Details’.
<code>envir</code>	environment in which the function should be defined.
<code>value</code>	an object, usually a language object : see section ‘Value’.

Details

For the first form, `fun` can be a character string naming the function to be manipulated, which is searched for from the parent frame. If it is not specified, the function calling `body` is used.

The bodies of all but the simplest are braced expressions, that is calls to `{`: see the ‘Examples’ section for how to create such a call.

Value

`body` returns the body of the function specified. This is normally a [language object](#), most often a call to `{`, but it can also be a [symbol](#) such as `pi` or a constant (e.g., `3` or `"R"`) to be the return value of the function.

The replacement form sets the body of a function to the object on the right hand side, and (potentially) resets the [environment](#) of the function, and drops [attributes](#). If `value` is of class `"expression"` the first element is used as the body: any additional elements are ignored, with a warning.

See Also

The three parts of a (non-primitive) function are its [formals](#), `body`, and [environment](#).

Further, see [alist](#), [args](#), [function](#).

Examples

```
body(body)
f <- function(x) x^5
body(f) <- quote(5^x)
## or equivalently body(f) <- expression(5^x)
f(3) # = 125
body(f)

## creating a multi-expression body
```

```
e <- expression(y <- x^2, return(y)) # or a list
body(f) <- as.call(c(as.name("{"), e))
f
f(8)
## Using substitute() may be simpler than 'as.call(c(as.name("{", ..)))':
stopifnot(identical(body(f), substitute({ y <- x^2; return(y) })))
```

bquote

*Partial substitution in expressions***Description**

An analogue of the LISP backquote macro. `bquote` quotes its argument except that terms wrapped in `.()` are evaluated in the specified `where` environment. If `splice = TRUE` then terms wrapped in `..()` are evaluated and spliced into a call.

Usage

```
bquote(expr, where = parent.frame(), splice = FALSE)
```

Arguments

<code>expr</code>	A language object .
<code>where</code>	An environment.
<code>splice</code>	Logical; if <code>TRUE</code> splicing is enabled.

Value

A [language object](#).

See Also

[quote](#), [substitute](#)

Examples

```
require(graphics)

a <- 2

bquote(a == a)
quote(a == a)

bquote(a == .(a))
substitute(a == A, list(A = a))

plot(1:10, a*(1:10), main = bquote(a == .(a)))

## to set a function default arg
default <- 1
bquote( function(x, y = .(default)) x+y )

exprs <- expression(x <- 1, y <- 2, x + y)
bquote(function() {..(exprs)}, splice = TRUE)
```

browser	<i>Environment Browser</i>
---------	----------------------------

Description

Interrupt the execution of an expression and allow the inspection of the environment where `browser` was called from.

Usage

```
browser(text = "", condition = NULL, expr = TRUE, skipCalls = 0L)
```

Arguments

<code>text</code>	a text string that can be retrieved once the browser is invoked.
<code>condition</code>	a condition that can be retrieved once the browser is invoked.
<code>expr</code>	a “condition”. By default, and whenever not false after being coerced to logical , the debugger will be invoked, otherwise control is returned directly.
<code>skipCalls</code>	how many previous calls to skip when reporting the calling context.

Details

A call to `browser` can be included in the body of a function. When reached, this causes a pause in the execution of the current expression and allows access to the R interpreter.

The purpose of the `text` and `condition` arguments are to allow helper programs (e.g., external debuggers) to insert specific values here, so that the specific call to `browser` (perhaps its location in a source file) can be identified and special processing can be achieved. The values can be retrieved by calling [browserText](#) and [browserCondition](#).

The purpose of the `expr` argument is to allow for the illusion of conditional debugging. It is an illusion, because execution is always paused at the call to `browser`, but control is only passed to the evaluator described below if `expr` is not `FALSE` after coercion to logical. In most cases it is going to be more efficient to use an `if` statement in the calling program, but in some cases using this argument will be simpler.

The `skipCalls` argument should be used when the `browser()` call is nested within another debugging function: it will look further up the call stack to report its location.

At the browser prompt the user can enter commands or R expressions, followed by a newline. The commands are

- `c` exit the browser and continue execution at the next statement.
- `cont` synonym for `c`.
- `f` finish execution of the current loop or function.
- `help` print this list of commands.
- `n` evaluate the next statement, stepping over function calls. For byte compiled functions interrupted by `browser` calls, `n` is equivalent to `c`.
- `s` evaluate the next statement, stepping into function calls. Again, byte compiled functions make `s` equivalent to `c`.
- `where` print a stack trace of all active function calls.

`r` invoke a "resume" restart if one is available; interpreted as an R expression otherwise. Typically "resume" restarts are established for continuing from user interrupts.

`Q` exit the browser and the current evaluation and return to the top-level prompt.

Leading and trailing whitespace is ignored, except for an empty line. Handling of empty lines depends on the "browserNLdisabled" [option](#); if it is TRUE, empty lines are ignored. If not, an empty line is the same as `n` (or `s`, if it was used most recently).

Anything else entered at the browser prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and `ls()` lists the objects in the calling frame. (If you want to look at an object with a name such as `n`, print it explicitly, or use `autoprint` via `(n)`).

The number of lines printed for the deparsed call can be limited by setting [options](#)(`deparse.max.lines`).

The browser prompt is of the form `Browse[n]>`: here `n` indicates the 'browser level'. The browser can be called when browsing (and often is when [debug](#) is in use), and each recursive call increases the number. (The actual number is the number of 'contexts' on the context stack: this is usually 2 for the outer level of browsing and 1 when examining dumps in [debugger](#).)

This is a primitive function but does argument matching in the standard way.

Interaction with Condition Handling

Because the browser prompt is implemented using the [restart and condition handling mechanism](#), it prevents error handlers set up before the breakpoint from being called or invoked. The implementation follows this model:

```
repeat withRestarts(
  withCallingHandlers(
    readEvalPrint(),
    error = function(cnd) {
      cat("Error:", conditionMessage(cnd), "\n")
      invokeRestart("browser")
    }
  ),
  browser = function(...) NULL
)

readEvalPrint <- function(env = parent.frame()) {
  print(eval(parse(prompt = "Browse[n]> "), env))
}
```

The restart invocation interrupts the lookup for condition handlers and transfers control to the next iteration of the debugger REPL.

Note that condition handlers for other classes (such as "warning") are still called and may cause a non-local transfer of control out of the debugger.

browserText

Functions to Retrieve Values Supplied by Calls to the Browser

Description

A call to `browser` can provide context by supplying either a text argument or a condition argument. These functions can be used to retrieve either of these arguments.

Usage

```
browserText(n = 1)
browserCondition(n = 1)
browserSetDebug(n = 1)
```

Arguments

`n` The number of contexts to skip over, it must be non-negative.

Details

Each call to `browser` can supply either a text string or a condition. The functions `browserText` and `browserCondition` provide ways to retrieve those values. Since there can be multiple `browser` contexts active at any time we also support retrieving values from the different contexts. The innermost (most recently initiated) `browser` context is numbered 1: other contexts are numbered sequentially.

`browserSetDebug` provides a mechanism for initiating the browser in one of the calling functions. See [sys.frame](#) for a more complete discussion of the calling stack. To use `browserSetDebug` you select some calling function, determine how far back it is in the call stack and call `browserSetDebug` with `n` set to that value. Then, by typing `c` at the browser prompt you will cause evaluation to continue, and provided there are no intervening calls to `browser` or other interrupts, control will halt again once evaluation has returned to the closure specified. This is similar to the up functionality in GDB or the "step out" functionality in other debuggers.

Value

`browserText` returns the text, while `browserCondition` returns the condition from the specified browser context.

`browserSetDebug` returns NULL, invisibly.

Note

It may be of interest to allow for querying further up the set of browser contexts and this functionality may be added at a later date.

[browser](#)

<code>builtins</code>	<i>Returns the Names of All Built-in Objects</i>
-----------------------	--

Description

Return the names of all the built-in objects. These are fetched directly from the symbol table of the R interpreter.

Usage

```
builtins(internal = FALSE)
```

Arguments

`internal` a logical indicating whether only ‘internal’ functions (which can be called via [.Internal](#)) should be returned.

Details

`builtins()` returns an unsorted list of the objects in the symbol table, that is all the objects in the base environment. These are the built-in objects plus any that have been added subsequently when the base package was loaded. It is less confusing to use `ls(baseenv(), all.names = TRUE)`.

`builtins(TRUE)` returns an unsorted list of the names of internal functions, that is those which can be accessed as `.Internal(foo(args ...))` for `foo` in the list.

Value

A character vector.

<code>by</code>	<i>Apply a Function to a Data Frame Split by Factors</i>
-----------------	--

Description

Function `by` is an object-oriented wrapper for [tapply](#) applied to data frames.

Usage

```
by(data, INDICES, FUN, ..., simplify = TRUE)
```

Arguments

<code>data</code>	an R object, normally a data frame, possibly a matrix.
<code>INDICES</code>	a factor or a list of factors, each of length <code>nrow(data)</code> . For the data frame method, <code>INDICES</code> can also be a formula as in the <code>f</code> argument of the <code>split</code> method for data frames.
<code>FUN</code>	a function to be applied to (usually data-frame) subsets of <code>data</code> .
<code>...</code>	further arguments to <code>FUN</code> .
<code>simplify</code>	logical: see tapply .

Details

A data frame is split (calling `split()`) by row into data frames subsetting by the values of one or more factors, and function `FUN` is applied to each subset in turn.

For the default method, an object with dimensions (e.g., a matrix) is coerced to a data frame and the data frame method applied. Other objects are also coerced to a data frame, but `FUN` is applied separately to (subsets of) each column of the data frame.

Value

An object of class "by", giving the results for each subset. This is always a list if `simplify` is false, otherwise a list or array (see [tapply](#)).

See Also

[tapply](#), [simplify2array](#). [array2DF](#) to convert result to a data frame. [ave](#) also applies a function block-wise.

Examples

```
require(stats)
by(warpbreaks[, 1:2], warpbreaks[, "tension"], summary)
by(warpbreaks[, 1], warpbreaks[, -1], summary)
by(warpbreaks, warpbreaks[, "tension"],
   function(x) lm(breaks ~ wool, data = x))

## now suppose we want to extract the coefficients by group
tmp1 <- with(warpbreaks,
             by(warpbreaks, tension,
                function(x) lm(breaks ~ wool, data = x)))
sapply(tmp1, coef)

## another way
by(warpbreaks, ~ tension,
   with, coef(lm(breaks ~ wool))) |> array2DF(simplify = TRUE)
```

Description

This is a generic function which combines its arguments.

The default method combines its arguments to form a vector. All arguments are coerced to a common type which is the type of the returned value, and all attributes except names are removed.

Usage

```
## S3 Generic function
c(...)

## Default S3 method:
c(..., recursive = FALSE, use.names = TRUE)
```

Arguments

<code>...</code>	objects to be concatenated. All <code>NULL</code> entries are dropped before method dispatch unless at the very beginning of the argument list.
<code>recursive</code>	logical. If <code>recursive = TRUE</code> , the function recursively descends through lists (and pairlists) combining all their elements into a vector.
<code>use.names</code>	logical indicating if <code>names</code> should be preserved.

Details

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`. Pairlists are treated as lists, whereas non-vector components (such as `names` / symbols and `calls`) are treated as one-element `lists` which cannot be unlisted even if `recursive = TRUE`.

If the output type is `complex`, logical, integer, and double NAs keep their imaginary parts zero when coerced, and hence will *not* become `NA_complex_` (with imaginary part NA).

There is a `c.factor` method which combines factors into a factor.

`c` is sometimes used for its side effect of removing attributes except names, for example to turn an `array` into a vector. `as.vector` is a more intuitive way to do this, but also drops names. Note that `c` methods other than the default are not required to remove attributes (and they will almost certainly preserve a class attribute).

This is a `primitive` function.

Value

`NULL` or an expression or a vector of an appropriate mode. (With no arguments the value is `NULL`.)

S4 methods

This function is S4 generic, but with argument list `(x, ...)`.

See Also

`unlist` and `as.vector` to produce attribute-free vectors.

Examples

```
c(1, 7:9)
c(1:5, 10.5, "next")

## uses with a single argument to drop attributes
x <- 1:4
names(x) <- letters[1:4]
x
c(x)          # has names
as.vector(x)  # no names
dim(x) <- c(2,2)
x
c(x)
as.vector(x)

## append to a list:
ll <- list(A = 1, c = "C")
## do not use
c(ll, d = 1:3) # which is == c(ll, as.list(c(d = 1:3)))
## but rather
c(ll, d = list(1:3)) # c() combining two lists

## descend through lists:
c(list(A = c(B = 1)), recursive = TRUE)
c(list(A = c(B = 1, C = 2), B = c(E = 7)), recursive = TRUE)
```

call

Function Calls

Description

Create or test for objects of `mode` "call" (or "(", see Details).

Usage

```
call(name, ...)
is.call(x)
as.call(x)
```

Arguments

<code>name</code>	a non-empty character string naming the function to be called.
<code>...</code>	arguments to be part of the call.
<code>x</code>	an arbitrary R object.

Details

`call` returns an unevaluated function call, that is, an unevaluated expression which consists of the named function applied to the given arguments (`name` must be a string which gives the name of a function to be called). Note that although the call is unevaluated, the arguments `...` are evaluated.

`call` is a primitive, so the first argument is taken as `name` and the remaining arguments as arguments for the constructed call: if the first argument is named the name must partially match `name`.

`is.call` is used to determine whether `x` is a call (i.e., of mode `"call"` or `"("`). Note that

- `is.call(x)` is strictly equivalent to `typeof(x) == "language"`.
- `is.language()` is also true for calls (but also for `symbols` and `expressions` where `is.call()` is false).
- When `is.call(cl)` is true, `class(cl)` typically returns `"call"`, except when `cl` is one of `if`, `for`, `while`, `(`, `{`, `<-`, `=`, which each has its own `class(cl)` (equal to the “function” name), see the ‘Special calls’ example.

`as.call(x)`: Objects of mode `"list"` can be coerced to mode `"call"`. The first element of the list becomes the function part of the call, so should be a function or the name of one (as a symbol; a character string will not do).

If you think of using `as.call(string)`, consider using `str2lang(string)` which is an efficient version of `parse(text=string)`. Note that `call()` and `as.call()`, when applicable, are much preferable to these `parse()` based approaches.

All three are `primitive` functions.

`as.call` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Warning

`call` should not be used to attempt to evade restrictions on the use of `.Internal` and other non-API calls.

See Also

[do.call](#) for calling a function by name and argument list; [Recall](#) for recursive calling of functions; further [is.language](#), [expression](#), [function](#).

Producing calls etc from character: [str2lang](#) and [parse](#).

Examples

```
is.call(call) #-> FALSE: Functions are NOT calls

## set up a function call to round with argument 10.5
cl <- call("round", 10.5)
is.call(cl) # TRUE
cl
identical(quote(round(10.5)), # <- less functional, but the same
cl) # TRUE
```

```

## such a call can also be evaluated.
eval(cl) # [1] 10

class(cl) # "call"
typeof(cl) # "language"
is.call(cl) && is.language(cl) # always TRUE for "call"s

A <- 10.5
call("round", A) # round(10.5)
call("round", quote(A)) # round(A)
f <- "round"
call(f, quote(A)) # round(A)
## if we want to supply a function we need to use as.call or similar
f <- round
## Not run: call(f, quote(A)) # error: first arg must be character
(g <- as.call(list(f, quote(A))))
eval(g)
## alternatively but less transparently
g <- list(f, quote(A))
mode(g) <- "call"
g
eval(g)

## Special calls (and some regular ones):
L <- as.list(E <- setNames( , c("if", "for", "while", "repeat", "function",
                              "(", "{", "[", "<=", "<<=", ">", "=")))
for(i in seq_along(L)) L[[i]] <- call(E[[i]]) # instead of lapply(E, call) ..
list_ <- function (...) `names<-`(list(...), vapply(sys.call()[1:L], as.character, ""))
(Tab <- noquote(sapply(list_(is.call, typeof, class, mode), \(F) sapply(L, F))))
## The 7 exceptions:
Tab[ Tab[, "class"] != "call" , c(3:4, 1:2)]

## see also the examples in the help for do.call

```

callCC

*Call With Current Continuation***Description**

A downward-only version of Scheme's call with current continuation.

Usage

```
callCC(fun)
```

Arguments

`fun` function of one argument, the exit procedure.

Details

`callCC` provides a non-local exit mechanism that can be useful for early termination of a computation. `callCC` calls `fun` with one argument, an *exit function*. The exit function takes a single argument, the intended return value. If the body of `fun` calls the exit function then the call to `callCC` immediately returns, with the value supplied to the exit function as the value returned by `callCC`.

Author(s)

Luke Tierney

Examples

```
# The following all return the value 1
callCC(function(k) 1)
callCC(function(k) k(1))
callCC(function(k) {k(1); 2})
callCC(function(k) repeat k(1))
```

CallExternal

Modern Interfaces to C/C++ code

Description

Functions to pass R objects to compiled C/C++ code that has been loaded into R.

Usage

```
.Call(.NAME, ..., PACKAGE)
.External(.NAME, ..., PACKAGE)
```

Arguments

<code>.NAME</code>	a character string giving the name of a C function, or an object of class <code>"NativeSymbolInfo"</code> , <code>"RegisteredNativeSymbol"</code> or <code>"NativeSymbol"</code> referring to such a name.
<code>...</code>	arguments to be passed to the compiled code. Up to 65 for <code>.Call</code> .
<code>PACKAGE</code>	if supplied, confine the search for a character string <code>.NAME</code> to the DLL given by this argument (plus the conventional extension, <code>‘.so’</code> , <code>‘.dll’</code> , ...). This argument follows <code>...</code> and so its name cannot be abbreviated. This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see ‘Note’).

Details

The functions are used to call compiled code which makes use of internal R objects, passing the arguments to the code as a sequence of R objects. They assume C calling conventions, so can usually also be used for C++ code.

For details about how to write code to use with these functions see the chapter **“System and foreign language interfaces”** in *Writing R Extensions*. They differ in the way the arguments are passed to the C code: `.External` allows for a variable or unlimited number of arguments.

These functions are `primitive`, and `.NAME` is always matched to the first argument supplied (which should not be named). For clarity, avoid using names in the arguments passed to `...` that match or partially match `.NAME`.

Value

An R object constructed in the compiled code.

Header files for external code

Writing code for use with these functions will need to use internal R structures defined in ‘Rinternals.h’ and/or the macros in ‘Rdefines.h’.

Note

If one of these functions is to be used frequently, do specify `PACKAGE` (to confine the search to a single DLL) or pass `.NAME` as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see `PACKAGE = "base"` for symbols linked into R. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.

`PACKAGE = ""` used to be accepted (but was undocumented): it is now an error.

capabilities

Report Capabilities of this Build of R

Description

Report on the optional features which have been compiled into this build of R.

Usage

```
capabilities(what = NULL,
             Xchk = any(nas %in% c("X11", "jpeg", "png", "tiff")))
```

Arguments

<code>what</code>	character vector or <code>NULL</code> , specifying required components. <code>NULL</code> implies that all are required.
<code>Xchk</code>	logical with a smart default, indicating if X11-related capabilities should be fully checked, notably on macOS. If set to false, may avoid a warning “No protocol specified” and e.g., the “X11” capability may be returned as NA.

Value

A named logical vector. Current components are

<code>jpeg</code>	is the <code>jpeg</code> function operational?
<code>png</code>	is the <code>png</code> function operational?
<code>tiff</code>	is the <code>tiff</code> function operational?
<code>tcltk</code>	is the <code>tcltk</code> package operational? Note that to make use of Tk you will almost always need to check that "X11" is also available.
<code>X11</code>	are the <code>X11</code> graphics device and the X11-based data editor available? This loads the X11 module if not already loaded, and checks that the default display can be contacted unless a X11 device has already been used.
<code>aqua</code>	is the <code>quartz</code> function operational? Only on some macOS builds, including CRAN binary distributions of R. Note that this is distinct from <code>.Platform\$GUI == "AQUA"</code> , which is true only when using the Mac R.app GUI console.
<code>http/ftp</code>	does the default method for <code>url</code> and <code>download.file</code> support 'http://' and 'ftp://' URLs? Always TRUE as from R 3.3.0. However, in recent versions the default method is "libcurl" which depends on an external library and it is conceivable that library might not support 'ftp://' in future.
<code>sockets</code>	are <code>make.socket</code> and related functions available? Always TRUE as from R 3.3.0.
<code>libxml</code>	is there support for integrating <code>libxml</code> with the R event loop? TRUE as from R 3.3.0, FALSE as from R 4.2.0.
<code>fifo</code>	are FIFO <code>connections</code> supported?
<code>cledit</code>	is command-line editing available in the current R session? This is false in non-interactive sessions. It will be true for the command-line interface if <code>readline</code> support has been compiled in and ' <code>--no-readline</code> ' was <i>not</i> used when R was invoked. (If ' <code>--interactive</code> ' was used, command-line editing will not actually be available.)
<code>iconv</code>	is internationalization conversion via <code>iconv</code> supported? Always true in current R.
<code>NLS</code>	is there Natural Language Support (for message translations)?
<code>Rprof</code>	is there support for <code>Rprof()</code> profiling? This is true if R was configured (before compilation) with default settings which include <code>--enable-R-profiling</code> .
<code>profmem</code>	is there support for memory profiling? See <code>tracemem</code> .
<code>cairo</code>	is there support for the <code>svg</code> , <code>cairo_pdf</code> and <code>cairo_ps</code> devices, and for <code>type = "cairo"</code> in the <code>bmp</code> , <code>jpeg</code> , <code>png</code> and <code>tiff</code> devices? Prior to R 4.1.0 this also indicated Cairo support in the <code>X11</code> device, but it is now possible to build R with Cairo support for the bitmap devices without support for the <code>X11</code> device (usually when that is not supported at all).
<code>ICU</code>	is ICU available for collation? See the help on <code>Comparison</code> and <code>icuSetCollate</code> : it is never used for a C locale.
<code>long.double</code>	does this build use a C long double type which is longer than double? Some platforms do not have such a type, and on others its use can be suppressed by the configure option ' <code>--disable-long-double</code> '. Although not guaranteed, it is a reasonable assumption that if present long doubles will have at least as much range and accuracy as the ISO/IEC 60559 80-bit 'extended precision' format. Since R 4.0.0 <code>.Machine</code> gives information on the long-double type (if present).

`libcurl` is `libcurl` available in this build? Used by function `curlGetHeaders` and optionally by `download.file` and `url`. As from R 3.3.0 always true for Unix-alikes, and as from R 4.2.0 true on Windows.

Note to macOS users

Capabilities `"jpeg"`, `"png"` and `"tiff"` refer to the X11-based versions of these devices. If `capabilities("aqua")` is true, then these devices with `type = "quartz"` will be available, and out-of-the-box will be the default type. Thus for example the `tiff` device will be available if `capabilities("aqua") || capabilities("tiff")` if the defaults are unchanged.

See Also

`.Platform`, `extSoftVersion`, and `grSoftVersion` (and links there) for availability of capabilities *external* to R but used from R functions.

Examples

```
capabilities()

if(!capabilities("ICU"))
  warning("ICU is not available")

## Does not call the internal X11-checking function:
capabilities(Xchk = FALSE)

## See also the examples for 'connections'.
```

cat

Concatenate and Print

Description

Outputs the objects, concatenating the representations. `cat` performs much less conversion than `print`.

Usage

```
cat(... , file = "", sep = " ", fill = FALSE, labels = NULL,
    append = FALSE)
```

Arguments

<code>...</code>	R objects (see ‘Details’ for the types of objects allowed).
<code>file</code>	a connection , or a character string naming the file to print to. If <code>"</code> (the default), <code>cat</code> prints to the standard output connection, the console unless redirected by sink . If it is <code>" cmd"</code> , the output is piped to the command given by ‘ <code>cmd</code> ’, by opening a pipe connection.
<code>sep</code>	a character vector of strings to append after each element, except the last. Elements of <code>sep</code> are used in turn and recycled as needed.

<code>fill</code>	a logical or (positive) numeric controlling how the output is broken into successive lines. If <code>FALSE</code> (default), only newlines created explicitly by <code>"\n"</code> are printed. Otherwise, the output is broken into lines with print width equal to the option <code>width</code> if <code>fill</code> is <code>TRUE</code> , or the value of <code>fill</code> if this is numeric. Linefeeds are only inserted <i>between</i> elements, strings wider than <code>fill</code> are not wrapped. Non-positive <code>fill</code> values are ignored, with a warning.
<code>labels</code>	character vector of labels for the lines printed. Ignored if <code>fill</code> is <code>FALSE</code> .
<code>append</code>	logical. Only used if the argument <code>file</code> is the name of file (and not a connection or <code>" cmd"</code>). If <code>TRUE</code> output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .

Details

`cat` is useful for producing output in user-defined functions. It converts its arguments to character vectors, concatenates them to a single character vector, appends the given `sep = string(s)` to each element, except the last, and then outputs them.

No line feeds (aka “newline”s) are output unless explicitly requested by `"\n"` or if generated by filling (if argument `fill` is `TRUE` or numeric).

If `file` is a connection and open for writing it is written from its current position. If it is not open, it is opened for the duration of the call in `"wt"` mode and then closed again.

Currently only `atomic` vectors and `names` are handled, together with `NULL` and other zero-length objects (which produce no output). Character strings are output ‘as is’ (unlike `print.default` which escapes non-printable characters and backslash — use `encodeString` if you want to output encoded strings using `cat`). Other types of R object should be converted (e.g., by `as.character` or `format`) before being passed to `cat`. That includes factors, which are output as integer vectors.

`cat` converts numeric/complex elements in the same way as `print` (and not in the same way as `as.character` which is used by the S equivalent), so `options "digits"` and `"scipen"` are relevant. However, it uses the minimum field width necessary for each element, rather than the same field width for all elements.

Value

None (invisible `NULL`).

Note

If any element of `sep` contains a newline character, an element is output after every vector element, and only a newline after the last. Entries are recycled as needed.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`print`, `format`, and `paste` which concatenates into a string.

Examples

```
iter <- stats::rpois(1, lambda = 10)
## print an informative message
cat("iteration = ", iter <- iter + 1, "\n")

## 'fill' and label lines:
cat(paste(letters, 100* 1:26), fill = TRUE, labels = paste0("{", 1:10, "}:"))
```

cbind

Combine R Objects by Rows or Columns

Description

Take a sequence of vector, matrix or data-frame arguments and combine by columns or rows, respectively. These are generic functions with methods for other R classes.

Usage

```
cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)
## S3 method for class 'data.frame'
rbind(..., deparse.level = 1, make.row.names = TRUE,
       stringsAsFactors = FALSE, factor.exclude = TRUE)
```

Arguments

`...` (generalized) vectors or matrices. These can be given as named arguments. Other R objects may be coerced as appropriate, or S4 methods may be used: see sections ‘Details’ and ‘Value’. (For the "data.frame" method of `cbind` these can be further arguments to `data.frame` such as `stringsAsFactors`.)

`deparse.level` integer controlling the construction of labels in the case of non-matrix-like arguments (for the default method):
`deparse.level = 0` constructs no labels;
the default `deparse.level = 1` typically and `deparse.level = 2` always construct labels from the argument names, see the ‘Value’ section below.

`make.row.names` (only for data frame method:) logical indicating if unique and valid `row.names` should be constructed from the arguments.

`stringsAsFactors` logical, passed to `as.data.frame`; only has an effect when the `...` arguments contain a (non-data.frame) `character`.

`factor.exclude` if the data frames contain factors, the default `TRUE` ensures that NA levels of factors are kept, see [PR#17562](#) and the ‘Data frame methods’. In R versions up to 3.6.x, `factor.exclude = NA` has been implicitly hardcoded (R <= 3.6.0) or the default (R = 3.6.x, x >= 1).

Details

The functions `cbind` and `rbind` are S3 generic, with methods for data frames. The data frame method will be used if at least one argument is a data frame and the rest are vectors or matrices. There can be other methods; in particular, there is one for time series objects. See the section on ‘Dispatch’ for how the method to be used is selected. If some of the arguments are of an S4 class, i.e., `isS4(.)` is true, S4 methods are sought also, and the hidden `cbind2` or `rbind2` functions from package **methods** maybe called, which in turn build on `cbind2` or `rbind2`, respectively. In that case, `deparse.level` is obeyed, similarly to the default method.

In the default method, all the vectors/matrices must be atomic (see `vector`) or lists. Expressions are not allowed. Language objects (such as formulae and calls) and pairlists will be coerced to lists: other objects (such as names and external pointers) will be included as elements in a list result. Any classes the inputs might have are discarded (in particular, factors are replaced by their internal codes).

If there are several matrix arguments, they must all have the same number of columns (or rows) and this will be the number of columns (or rows) of the result. If all the arguments are vectors, the number of columns (rows) in the result is equal to the length of the longest vector. Values in shorter arguments are recycled to achieve this length (with a `warning` if they are recycled only *fractionally*).

When the arguments consist of a mix of matrices and vectors the number of columns (rows) of the result is determined by the number of columns (rows) of the matrix arguments. Any vectors have their values recycled or subsetting to achieve this length.

For `cbind` (`rbind`), vectors of zero length (including `NULL`) are ignored unless the result would have zero rows (columns), for S compatibility. (Zero-extent matrices do not occur in S3 and are not ignored in R.)

Matrices are restricted to less than 2^{31} rows and columns even on 64-bit systems. So input vectors have the same length restriction: as from R 3.2.0 input matrices with more elements (but meeting the row and column restrictions) are allowed.

Value

For the default method, a matrix combining the . . . arguments column-wise or row-wise. (Exception: if there are no inputs or all the inputs are `NULL`, the value is `NULL`.)

The type of a matrix result determined from the highest type of any of the inputs in the hierarchy `raw < logical < integer < double < complex < character < list`.

For `cbind` (`rbind`) the column (row) names are taken from the `colnames` (`rownames`) of the arguments if these are matrix-like. Otherwise from the names of the arguments or where those are not supplied and `deparse.level > 0`, by deparsing the expressions given, for `deparse.level = 1` only if that gives a sensible name (a ‘symbol’, see `is.symbol`).

For `cbind` row names are taken from the first argument with appropriate names: `rownames` for a matrix, or names for a vector of length the number of rows of the result.

For `rbind` column names are taken from the first argument with appropriate names: `colnames` for a matrix, or names for a vector of length the number of columns of the result.

Data frame methods

The `cbind` data frame method is just a wrapper for `data.frame(..., check.names = FALSE)`. This means that it will split matrix columns in data frame arguments.

The `rbind` data frame method first drops all zero-column and zero-row arguments. (If that leaves none, it returns the first argument with columns otherwise a zero-column zero-row data frame.)

It then takes the classes of the columns from the first data frame, and matches columns by name (rather than by position). Factors have their levels expanded as necessary (in the order of the levels of the level sets of the factors encountered) and the result is an ordered factor if and only if all the components were ordered factors. Old-style categories (integer vectors with levels) are promoted to factors.

Note that for result column j , `factor(., exclude = X(j))` is applied, where

```
X(j) := if(isTRUE(factor.exclude)) {
      if(!NA.lev[j]) NA # else NULL
    } else factor.exclude
```

where `NA.lev[j]` is true iff any contributing data frame has had a `factor` in column j with an explicit NA level.

Dispatch

The method dispatching is *not* done via `UseMethod()`, but by C-internal dispatching. Therefore there is no need for, e.g., `rbind.default`.

The dispatch algorithm is described in the source file (`'.../src/main/bind.c'`) as

1. For each argument we get the list of possible class memberships from the class attribute.
2. We inspect each class in turn to see if there is an applicable method.
3. If we find a method, we use it. Otherwise, if there was an S4 object among the arguments, we try S4 dispatch; otherwise, we use the default code.

If you want to combine other objects with data frames, it may be necessary to coerce them to data frames first. (Note that this algorithm can result in calling the data frame method if all the arguments are either data frames or vectors, and this will result in the coercion of character vectors to factors.)

See Also

`c` to combine vectors (and lists) as vectors, `data.frame` to combine vectors and matrices as a data frame.

Examples

```
m <- cbind(1, 1:7) # the '1' (= shorter vector) is recycled
m
m <- cbind(m, 8:14)[, c(1, 3, 2)] # insert a column
m
cbind(1:7, diag(3)) # vector is subset -> warning

cbind(0, rbind(1, 1:3))
cbind(I = 0, X = rbind(a = 1, b = 1:3)) # use some names
xx <- data.frame(I = rep(0,2))
cbind(xx, X = rbind(a = 1, b = 1:3)) # named differently

cbind(0, matrix(1, nrow = 0, ncol = 4)) #> Warning (making sense)
dim(cbind(0, matrix(1, nrow = 2, ncol = 0))) #> 2 x 1
```

```
## deparse.level
dd <- 10
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 0) # middle 2 rownames
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 1) # 3 rownames (default)
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 2) # 4 rownames

## cheap row names:
b0 <- gl(3,4, labels=letters[1:3])
bf <- setNames(b0, paste0("o", seq_along(b0)))
df <- data.frame(a = 1, B = b0, f = gl(4,3))
df. <- data.frame(a = 1, B = bf, f = gl(4,3))
new <- data.frame(a = 8, B = "B", f = "1")
(df1 <- rbind(df, new))
(df.1 <- rbind(df., new))
stopifnot(identical(df1, rbind(df, new, make.row.names=FALSE)),
           identical(df.1, rbind(df., new, make.row.names=FALSE)))
```

char.expand

Expand a String with Respect to a Target Table

Description

Seeks a unique match of its first argument among the elements of its second. If successful, it returns this element; otherwise, it performs an action specified by the third argument.

Usage

```
char.expand(input, target, nomatch = stop("no match"))
```

Arguments

input	a character string to be expanded.
target	a character vector with the values to be matched against.
nomatch	an R expression to be evaluated in case expansion was not possible.

Details

This function is particularly useful when abbreviations are allowed in function arguments, and need to be uniquely expanded with respect to a target table of possible values.

Value

A length-one character vector, one of the elements of `target` (unless `nomatch` is changed to be a non-error, when it can be a zero-length character string).

See Also

[charmatch](#) and [pmatch](#) for performing partial string matching.

Examples

```
locPars <- c("mean", "median", "mode")
char.expand("me", locPars, warning("Could not expand!"))
char.expand("mo", locPars)
```

character

*Character Vectors***Description**

Create or test for objects of type "character".

Usage

```
character(length = 0)
as.character(x, ...)
is.character(x)
```

Arguments

length	a non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

`as.character` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). Its default method calls `as.vector`, so, only if `is.object(x)` is true, dispatch is first on methods for `as.character` and then for methods for `as.vector`.

`as.character` represents real and complex numbers to 15 significant digits (technically the compiler's setting of the ISO C constant `DBL_DIG`, which will be 15 on machines supporting IEC 60559 arithmetic according to the C99 standard). This ensures that all the digits in the result will be reliable (and not the result of representation error), but does mean that conversion to character and back to numeric may change the number. If you want to convert numbers to character with the maximum possible precision, use `format`.

Value

`character` creates a character vector of the specified length. The elements of the vector are all equal to "".

`as.character` attempts to coerce its argument to character type; like `as.vector` it strips attributes including names. For lists and pairlists (including [language objects](#) such as calls) it deparses the elements individually, except that it extracts the first element of length-one character vectors, see the `Abc` example.

`is.character` returns TRUE or FALSE depending on whether its argument is of character type or not.

Note

`as.character` breaks lines in language objects at 500 characters, and inserts newlines. Prior to 2.15.0 lines were truncated.

See Also

[options](#): options `scipen` and `OutDec` affect the conversion of numbers.

[paste](#), [substr](#) and [strsplit](#) for character concatenation and splitting, [chartr](#) for character translation and case folding (e.g., upper to lower case) and [sub](#), [grep](#) etc for string matching and substitutions. Note that `help.search(keyword = "character")` gives even more links.

[deparse](#), which is normally preferable to `as.character` for [language objects](#).

[Quotes](#) on how to specify character / string constants, including *raw* ones.

Examples

```
form <- y ~ a + b + c
as.character(form) ## length 3
deparse(form)      ## like the input

a0 <- 11/999          # has a repeating decimal representation
(a1 <- as.character(a0))
format(a0, digits = 16) # shows 1 to 2 more digit(s)
a2 <- as.numeric(a1)
a2 - a0                # normally around -1e-17
as.character(a2)       # possibly different from a1
print(c(a0, a2), digits = 16)

as.character(list(A = "Abc", xy = c("x", "y"))) # "Abc" "c(\"x\", \"y\")"
## i.e., "Abc" directly instead of deparsing to "\"Abc\""
```

charmatch

Partial String Matching

Description

`charmatch` seeks matches for the elements of its first argument among those of its second.

Usage

```
charmatch(x, table, nomatch = NA_integer_)
```

Arguments

<code>x</code>	the values to be matched: converted to a character vector by as.character . Long vectors are supported.
<code>table</code>	the values to be matched against: converted to a character vector. Long vectors are not supported.
<code>nomatch</code>	the (integer) value to be returned at non-matching positions.

Details

Exact matches are preferred to partial matches (those where the value to be matched has an exact match to the initial part of the target, but the target is longer).

If there is a single exact match or no exact match and a unique partial match then the index of the matching value is returned; if multiple exact or multiple partial matches are found then 0 is returned and if no match is found then `nomatch` is returned.

NA values are treated as the string constant "NA".

Value

An integer vector of the same length as `x`, giving the indices of the elements in `table` which matched, or `nomatch`.

Author(s)

This function is based on a C function written by Terry Therneau.

See Also

[pmatch](#), [match](#).

[startsWith](#) for another matching of initial parts of strings; [grep](#) or [regexpr](#) for more general (regex) matching of strings.

Examples

```
charmatch("", "") # returns 1
charmatch("m", c("mean", "median", "mode")) # returns 0
charmatch("med", c("mean", "median", "mode")) # returns 2
```

chartr

Character Translation and Case Folding

Description

Translate characters in character vectors, in particular from upper to lower case or vice versa.

Usage

```
chartr(old, new, x)
tolower(x)
toupper(x)
casefold(x, upper = FALSE)
```

Arguments

<code>x</code>	a character vector, or an object that can be coerced to character by as.character .
<code>old</code>	a character string specifying the characters to be translated. If a character vector of length 2 or more is supplied, the first element is used with a warning.
<code>new</code>	a character string specifying the translations. If a character vector of length 2 or more is supplied, the first element is used with a warning.
<code>upper</code>	logical: translate to upper or lower case?

Details

`chartr` translates each character in `x` that is specified in `old` to the corresponding character specified in `new`. Ranges are supported in the specifications, but character classes and repeated characters are not. If `old` contains more characters than `new`, an error is signaled; if it contains fewer characters, the extra characters at the end of `new` are ignored. To include a literal – that should not denote a range, make it the first or the last character in the specification.

`tolower` and `toupper` convert upper-case characters in a character vector to lower-case, or vice versa. Non-alphabetic characters are left unchanged. More than one character can be mapped to a single upper-case character.

`casefold` is a wrapper for `tolower` and `toupper` originally written for compatibility with S-PLUS.

Value

A character vector of the same length and with the same attributes as `x` (after possible coercion).

Elements of the result will have the encoding declared as that of the current locale (see [Encoding](#)) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8. The result will be in the current locale's encoding unless the corresponding input was in UTF-8 or Latin-1, when it will be in UTF-8.

Note

These functions are platform-dependent, usually using OS services. The latter can be quite deficient, for example only covering ASCII characters in 8-bit locales. The definition of ‘alphabetic’ is platform-dependent and liable to change over time as most platforms are based on the frequently-updated Unicode tables.

See Also

[sub](#) and [gsub](#) for other substitutions in strings.

Examples

```
x <- "MiXeD cAsE 123"
chartr("iXs", "why", x)
chartr("a-cX", "D-Fw", x)
tolower(x)
toupper(x)

## "Mixed Case" Capitalizing - toupper( every first letter of a word ) :

.simpleCap <- function(x) {
  s <- strsplit(x, " ")[[1]]
  paste(toupper(substring(s, 1, 1)), substring(s, 2),
        sep = "", collapse = " ")
}

.simpleCap("the quick red fox jumps over the lazy brown dog")
## -> [1] "The Quick Red Fox Jumps Over The Lazy Brown Dog"

## and the better, more sophisticated version:
capwords <- function(s, strict = FALSE) {
  cap <- function(s) paste(toupper(substring(s, 1, 1)),
                           {s <- substring(s, 2); if(strict) tolower(s) else s},
                           sep = "", collapse = " ")
  capwords <- function(s) {
    s <- strsplit(s, " ")[[1]]
    sapply(s, cap)
  }
  capwords(s)
```

```

    sapply(strsplit(s, split = " "), cap, USE.NAMES = !is.null(names(s)))
  }
capwords(c("using AIC for model selection"))
## -> [1] "Using AIC For Model Selection"
capwords(c("using AIC", "for MODEL selection"), strict = TRUE)
## -> [1] "Using Aic" "For Model Selection"
##           ^^^      ^^^^^
##           'bad'    'good'

## -- Very simple insecure crypto --
rot <- function(ch, k = 13) {
  p0 <- function(...) paste(c(...), collapse = "")
  A <- c(letters, LETTERS, " ")
  I <- seq_len(k); chartr(p0(A), p0(c(A[-I], A[I])), ch)
}

pw <- "my secret pass phrase"
(cryp pw <- rot(pw, 13)) #-> you can send this off

## now ``decrypt`` :
rot(cryp pw, 54 - 13) # -> the original:
stopifnot(identical(pw, rot(cryp pw, 54 - 13)))

```

chkDots

Warn About Extraneous Arguments in the "... of Its Caller

Description

Warn about extraneous arguments in the ... of its caller. A utility to be used e.g., in S3 methods which need a formal ... argument but do not make any use of it. This helps catching user errors in calling the function in question (which is the caller of `chkDots()`).

Usage

```
chkDots(..., which.call = -1, allowed = character(0))
```

Arguments

...	“the dots”, as passed from the caller.
which.call	passed to <code>sys.call()</code> . A caller may use -2 if the message should mention <i>its</i> caller.
allowed	character vector of <i>named</i> elements in ... which are “allowed” and hence not warned about.

Author(s)

Martin Maechler, first version outside base, June 2012.

See Also

[warning](#),

Examples

```
seq.default ## <- you will see ' chkDots(...) '

seq(1,5, foo = "bar") # gives warning via chkDots()

## warning with more than one ...-entry:
density.f <- function(x, ...) NextMethod("density")
x <- density(structure(rnorm(10), class="f"), bar=TRUE, baz=TRUE)
```

chol

The Cholesky Decomposition

Description

Compute the Cholesky factorization of a real symmetric positive-definite square matrix.

Usage

```
chol(x, ...)
```

Default S3 method:

```
chol(x, pivot = FALSE, LINPACK = FALSE, tol = -1, ...)
```

Arguments

<code>x</code>	an object for which a method exists. The default method applies to numeric (or logical) symmetric, positive-definite matrices.
<code>...</code>	arguments to be passed to or from methods.
<code>pivot</code>	logical: should pivoting be used?
<code>LINPACK</code>	logical. Defunct and gives an error.
<code>tol</code>	a numeric tolerance for use with <code>pivot = TRUE</code> .

Details

`chol` is generic: the description here applies to the default method.

Note that only the upper triangular part of `x` is used, so that $R'R = x$ when `x` is symmetric.

If `pivot = FALSE` and `x` is not non-negative definite an error occurs. If `x` is positive semi-definite (i.e., some zero eigenvalues) an error will also occur as a numerical tolerance is used.

If `pivot = TRUE`, then the Cholesky decomposition of a (rearranged) positive semi-definite `x` can be computed. The rank of `x` is returned as `attr(Q, "rank")`, subject to numerical errors. The pivot is returned as `attr(Q, "pivot")`. It is no longer the case that `t(Q) %*% Q` equals `x`. However, setting `pivot <- attr(Q, "pivot")` and `oo <- order(pivot)`, it is true that `t(Q[, oo]) %*% Q[, oo]` equals `x`, or, alternatively, `t(Q) %*% Q` equals `x[pivot, pivot]`. Notice also, that `Q[, oo]` is typically not triangular. See the examples.

NOTE: For versions of R up to 4.5.x, the above wasn't quite true, since LAPACK does not zero out the rows of `Q` beyond the rank. This is now done in R, but if you want code to be compatible with earlier versions of R, you may want to ensure that you only use the first `rank` rows.

The value of `tol` is passed to LAPACK, with negative values selecting the default tolerance of (usually) `nrow(x) * .Machine$double.neg.eps * max(diag(x))`. The algorithm terminates once the pivot is less than `tol`.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The upper triangular factor of the Cholesky decomposition, i.e., the matrix R such that $R'R = x$ (see example).

If pivoting is used, then two additional attributes `"pivot"` and `"rank"` are also returned.

Warning

The code does not check for symmetry.

If `pivot = TRUE` and `x` is not non-negative definite then there will be a warning message but a meaningless result will occur. So only use `pivot = TRUE` when `x` is non-negative definite by construction.

See Also

[chol2inv](#) for its *inverse* (without pivoting), [backsolve](#) for solving linear systems with upper triangular left sides.

[qr](#), [svd](#) for related matrix factorizations.

Examples

```
( m <- matrix(c(5,1,1,3),2,2) )
( cm <- chol(m) )
t(cm) %*% cm #-- = 'm'
crossprod(cm) #-- = 'm'

# now for something positive semi-definite
x <- matrix(c(1:5, (1:5)^2), 5, 2)
x <- cbind(x, x[, 1] + 3*x[, 2], 2*x[, 1] + x[, 2])
colnames(x) <- letters[20:23]
m <- crossprod(x)
qr(m)$rank # is 2, as it should be
```

```

# chol() may fail, depending on numerical rounding:
# chol() unlike qr() does not use a tolerance.
try(chol(m))

(Q <- chol(m, pivot = TRUE))
## we can use this by
pivot <- attr(Q, "pivot")
crossprod(Q[, order(pivot)]) # recover m

## now for a non-positive-definite matrix
( m <- matrix(c(5,-5,-5,3), 2, 2) )
try(chol(m)) # fails
(Q <- chol(m, pivot = TRUE)) # warning
crossprod(Q) # not equal to m

## another example, this time with positive, negative, and zero eigenvalues
## notice that this (and the previous example) gets the rank wrong - it
## returns the rank of an approximating positive semidefinite matrix,
## effectively discounting negative eigenvalues.
(m <- matrix(c(1,1,2, 1,1,2, 2,2,1), 3, 3))
(Q <- chol(m, pivot=TRUE))
eigen(m)$values

## conjecture: indefinite cases should be detectable by comparing the
## diagonal of the reconstructed matrix to the original
piv <- attr(Q, "pivot")
(D <- diag(crossprod(Q))) ## faster: colSums(Q^2)
diag(m)[piv] - D

```

chol2inv

*Inverse from Cholesky (or QR) Decomposition***Description**

Invert a symmetric, positive definite square matrix from its Cholesky decomposition. Equivalently, compute $(X'X)^{-1}$ from the (R part) of the QR decomposition of X .

Usage

```
chol2inv(x, size = NCOL(x), LINPACK = FALSE)
```

Arguments

<code>x</code>	a matrix. The first <code>size</code> columns of the upper triangle contain the Cholesky decomposition of the matrix to be inverted.
<code>size</code>	the number of columns of <code>x</code> containing the Cholesky decomposition.
<code>LINPACK</code>	logical. Defunct and gives an error.

Value

The inverse of the matrix whose Cholesky decomposition was given.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Source

```

chooseOpsMethod	<i>Choose the Appropriate Method for Ops</i>
-----------------	--

Description

chooseOpsMethod is a function called by the Ops Group Generic when two suitable methods are found for a given call. It determines which method to use for the operation based on the objects being dispatched.

The function is first called with `reverse = FALSE`, where `x` corresponds to the first argument and `y` to the second argument of the group generic call. If `chooseOpsMethod()` returns `FALSE` for `x`, then `chooseOpsMethod` is called again, with `x` and `y` swapped, `mx` and `my` swapped, and `reverse = TRUE`.

Usage

```
chooseOpsMethod(x, y, mx, my, cl, reverse)
```

Arguments

<code>x, y</code>	the objects being dispatched on by the group generic.
<code>mx, my</code>	the methods found for objects <code>x</code> and <code>y</code> .
<code>cl</code>	the call to the group generic.
<code>reverse</code>	logical value indicating whether <code>x</code> and <code>y</code> are reversed from the way they were supplied to the generic.

Value

This function must return either TRUE or FALSE. A value of TRUE indicates that method `mx` should be used.

See Also

[Ops](#)

Examples

```
# Create two objects with custom Ops methods
foo_obj <- structure(1, class = "foo")
bar_obj <- structure(1, class = "bar")

`+.foo` <- function(e1, e2) "foo"
Ops.bar <- function(e1, e2) "bar"

invisible(foo_obj + bar_obj) # Warning: Incompatible methods

chooseOpsMethod.bar <- function(x, y, mx, my, cl, reverse) TRUE

stopifnot(exprs = {
  identical(foo_obj + bar_obj, "bar")
  identical(bar_obj + foo_obj, "bar")
})

# cleanup
rm(foo_obj, bar_obj, `+.foo`, Ops.bar, chooseOpsMethod.bar)
```

class

Object Classes

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class of the first argument to the generic function.

Usage

```
class(x)
class(x) <- value
unclass(x)
inherits(x, what, which = FALSE)
nameOfClass(x)
isa(x, what)

oldClass(x)
oldClass(x) <- value
.class2(x)
```

Arguments

<code>x</code>	an R object.
<code>what, value</code>	a character vector naming classes. <code>value</code> can also be <code>NULL</code> . <code>what</code> can also be a non-character R object with a <code>nameOfClass()</code> method.
<code>which</code>	logical affecting return value: see ‘Details’.

Details

Here, we describe the so called “S3” classes (and methods). For “S4” classes (and methods), see ‘Formal classes’ below.

Many R objects have a `class` attribute, a character vector giving the names of the classes from which the object *inherits*. (Functions `oldClass` and `oldClass<-` get and set the attribute, which can also be done directly.)

If the object does not have a class attribute, it has an implicit class, notably `"matrix"`, `"array"`, `"function"` or `"numeric"` or the result of `typeof(x)` (which is similar to `mode(x)`), but for type `"language"` and `mode "call"`, where the following extra classes exist for the corresponding function calls: `if`, `for`, `while`, `(, {, <-, =`.

Note that for objects `x` of an implicit (or an S4) class, when a (S3) generic function `foo(x)` is called, method dispatch may use more classes than are returned by `class(x)`, e.g., for a numeric matrix, the `foo.numeric()` method may apply. The exact full character vector of the classes which `UseMethod()` uses, is available as `.class2(x)` since R version 4.0.0. (This also applies to S4 objects when S3 dispatch is considered, see below.)

Beware that using `.class2()` for other reasons than didactical, diagnostical or for debugging may rather be a misuse than smart.

`NULL` objects (of implicit class `"NULL"`) cannot have attributes (hence no `class` attribute) and attempting to assign a class is an error.

When a generic function `fun` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found, a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used (if it exists). If there is no class attribute, the implicit class is tried, then the default method.

The function `class` prints the vector of names of classes an object inherits from. Correspondingly, `class<-` sets the classes an object inherits from. Assigning an empty character vector or `NULL` removes the class attribute, as for `oldClass<-` or direct attribute setting. Whereas it is clearer to explicitly assign `NULL` to remove the class, using an empty vector is more natural in e.g., `class(x) <- setdiff(class(x), "ts")`.

`unclass` returns (a copy of) its argument with its class attribute removed. (It is not allowed for objects which cannot be copied, namely environments and external pointers.)

`inherits` indicates whether its first argument inherits from any of the classes specified in the `what` argument. If `which` is `TRUE` then an integer vector of the same length as `what` is returned. Each element indicates the position in the `class(x)` matched by the element of `what`; zero indicates no match. If `which` is `FALSE` then `TRUE` is returned by `inherits` if any of the names in `what` match with any class.

`nameOfClass` is an S3 generic. It is called by `inherits` to get the class name for `what`, allowing for `what` to be values other than a character vector. `nameOfClass` methods are expected to return a character vector of length 1.

`isa` tests whether `x` is an object of class(es) as given in `what` by using `is` if `x` is an S4 object, and otherwise giving `TRUE` iff *all* elements of `what` are contained in `class(x)`.

All but `inherits` and `isa` are **primitive** functions.

Formal classes

An additional mechanism of *formal* classes, nicknamed “S4”, is available in package **methods** which is attached by default. For objects which have a formal class, its name is returned by `class` as a character vector of length one and method dispatch can happen on *several* arguments, instead of only the first. However, S3 method selection attempts to treat objects from an S4 class as if they had the appropriate S3 class attribute, as does `inherits`. Therefore, S3 methods can be defined for S4 classes. See the ‘[Introduction](#)’ and ‘[Methods_for_S3](#)’ help pages for basic information on S4 methods and for the relation between these and S3 methods.

The replacement version of the function sets the class to the value provided. For classes that have a formal definition, directly replacing the class this way is strongly deprecated. The expression `as(object, value)` is the way to coerce an object to a particular class.

The analogue of `inherits` for formal classes is `is`. The two functions behave consistently with one exception: S4 classes can have conditional inheritance, with an explicit test. In this case, `is` will test the condition, but `inherits` ignores all conditional superclasses.

Note

`UseMethod` dispatches on the class as returned by `class` (with some interpolated classes: see the [link](#)) rather than `oldClass`. *However*, [group generics](#) dispatch on the `oldClass` for efficiency, and [internal generics](#) only dispatch on objects for which `is.object` is true.

See Also

[UseMethod](#), [NextMethod](#), ‘[group generic](#)’, ‘[internal generic](#)’

Examples

```
x <- 10
class(x) # "numeric"
oldClass(x) # NULL
inherits(x, "a") #FALSE
class(x) <- c("a", "b")
inherits(x, "a") #TRUE
inherits(x, "a", TRUE) # 1
inherits(x, c("a", "b", "c"), TRUE) # 1 2 0

class( quote(pi) )           # "name"
## regular calls
class( quote(sin(pi*x)) )    # "call"
## special calls
class( quote(x <- 1) )       # "<-"
class( quote((1 < 2)) )      # "("
class( quote( if(8<3) pi ) ) # "if"

.class2(pi)                  # "double" "numeric"
.class2(matrix(1:6, 2,3))    # "matrix" "array" "integer" "numeric"
```

col

*Column Indexes***Description**

Returns a matrix of integers indicating their column number in a matrix-like object, or a factor of column labels.

Usage

```
col(x, as.factor = FALSE)
.col(dim)
```

Arguments

<code>x</code>	a matrix-like object, that is one with a two-dimensional <code>dim</code> .
<code>dim</code>	a matrix dimension, i.e., an integer valued numeric vector of length two (with non-negative entries).
<code>as.factor</code>	a logical value indicating whether the value should be returned as a factor of column labels (created if necessary) rather than as numbers.

Value

An integer (or factor) matrix with the same dimensions as `x` and whose i j -th element is equal to j (or the j -th column label).

See Also

`row` to get rows; `slice.index` for a general way to get slice indices in an array.

Examples

```
# extract an off-diagonal of a matrix
ma <- matrix(1:12, 3, 4)
ma[row(ma) == col(ma) + 1]

# create an identity 5-by-5 matrix more slowly than diag(n = 5):
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1

(i34 <- .col(3:4))
stopifnot(identical(i34, .col(c(3,4)))) # 'dim' maybe "double"
```

Colon

*Colon Operator***Description**

Generate regular sequences.

Usage

```
from:to
a:b
```

Arguments

<code>from</code>	starting value of sequence.
<code>to</code>	(maximal) end value of the sequence.
<code>a, b</code>	factors of the same length.

Details

The binary operator `:` has two meanings: for factors `a:b` is equivalent to [interaction](#)(`a`, `b`) (but the levels are ordered and labelled differently).

For other arguments `from:to` is equivalent to `seq(from, to)`, and generates a sequence from `from` to `to` in steps of 1 or -1. Value `to` will be included if it differs from `from` by an integer up to a numeric fuzz of about $1e-7$. Non-numeric arguments are coerced internally (hence without dispatching methods) to numeric—complex values will have their imaginary parts discarded with a warning.

Value

For numeric arguments, a numeric vector. This will be of type [integer](#) if `from` is integer-valued and the result is representable in the R integer type, otherwise of type "double" (aka [mode "numeric"](#)).

For factors, an unordered factor with levels labelled as `1a:1b` and ordered lexicographically (that is, `1b` varies fastest).

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

(for numeric arguments: S does not have `:` for factors.)

See Also

[seq](#) (a *generalization* of `from:to`).

As an alternative to using `:` for factors, [interaction](#).

For `:` used in the formal representation of an interaction, see [formula](#).

Examples

```
1:4
pi:6 # real
6:pi # integer

f1 <- gl(2, 3); f1
f2 <- gl(3, 2); f2
f1:f2 # a factor, the "cross" f1 x f2
```

colSums

Form Row and Column Sums and Means

Description

Form (generalized) row and column sums and means for numeric arrays (or data frames).

Usage

```
colSums (x, na.rm = FALSE, dims = 1)
rowSums (x, na.rm = FALSE, dims = 1)
colMeans(x, na.rm = FALSE, dims = 1)
rowMeans(x, na.rm = FALSE, dims = 1)

.colSums (x, m, n, na.rm = FALSE)
.rowSums (x, m, n, na.rm = FALSE)
.colMeans(x, m, n, na.rm = FALSE)
.rowMeans(x, m, n, na.rm = FALSE)
```

Arguments

<code>x</code>	an array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame. For <code>.colSums()</code> etc, a numeric, integer or logical matrix (or vector of length $m * n$).
<code>na.rm</code>	logical. Should missing values (including NaN) be omitted from the calculations?
<code>dims</code>	integer number: Which dimensions are regarded as ‘rows’ or ‘columns’ to sum over. For <code>row*</code> , the sum or mean is over dimensions <code>dims+1, ...</code> ; for <code>col*</code> it is over dimensions <code>1:dims</code> .
<code>m, n</code>	the dimensions of the matrix <code>x</code> for <code>.colSums()</code> etc.

Details

These functions are equivalent to use of [apply](#) with `FUN = mean` or `FUN = sum` with appropriate margins, but are a lot faster. As they are written for speed, they blur over some of the subtleties of NaN and NA. If `na.rm = FALSE` and either NaN or NA appears in a sum, the result will be one of NaN or NA, but which might be platform-dependent.

Notice that omission of missing values is done on a per-column or per-row basis, so column means may not be over the same set of rows, and vice versa. To use only complete rows or columns, first select them with [na.omit](#) or [complete.cases](#) (possibly on the transpose of `x`).

The versions with an initial dot in the name (`.colSums()` etc) are ‘bare-bones’ versions for use in programming: they apply only to numeric (like) matrices and do not name the result.

Value

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. For the first four functions the `dimnames` (or `names` for a vector result) are taken from the original array.

If there are no values in a range to be summed over (after removing missing values with `na.rm = TRUE`), that component of the output is set to 0 (`*Sums`) or NaN (`*Means`), consistent with [sum](#) and [mean](#).

See Also

[apply](#), [rowsum](#)

Examples

```
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
rowSums(x); colSums(x)
dimnames(x)[[1]] <- letters[1:8]
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
x[] <- as.integer(x)
rowSums(x); colSums(x)
x[] <- x < 3
rowSums(x); colSums(x)
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)

## an array
dim(UCBAdmissions)
rowSums(UCBAdmissions); rowSums(UCBAdmissions, dims = 2)
colSums(UCBAdmissions); colSums(UCBAdmissions, dims = 2)

## complex case
x <- cbind(x1 = 3 + 2i, x2 = c(4:1, 2:5) - 5i)
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)
```

commandArgs

Extract Command Line Arguments

Description

Provides access to a copy of the command line arguments supplied when this R session was invoked.

Usage

```
commandArgs(trailingOnly = FALSE)
```

Arguments

`trailingOnly` logical. Should only arguments after ‘`--args`’ be returned?

Details

These arguments are captured before the standard R command line processing takes place. This means that they are the unmodified values. This is especially useful with the ‘`--args`’ command-line flag to R, as all of the command line after that flag is skipped.

Value

A character vector containing the name of the executable and the user-supplied command line arguments. The first element is the name of the executable by which R was invoked. The exact form of this element is platform dependent: it may be the fully qualified name, or simply the last component (or basename) of the application, or for an embedded R it can be anything the programmer supplied.

If `trailingOnly = TRUE`, a character vector of those arguments (if any) supplied after ‘`--args`’.

See Also

[R.home\(\)](#), [Startup](#) and [BATCH](#)

Examples

```
commandArgs()
## Spawn a copy of this application as it was invoked,
## subject to shell quoting issues
## system(paste(commandArgs(), collapse = " "))
```

comment

Query or Set a "comment" Attribute

Description

These functions set and query a *comment* attribute for any R objects. This is typically useful for [data.frames](#) or model fits.

Contrary to other [attributes](#), the `comment` is not printed (by [print](#) or [print.default](#)).

Assigning `NULL` or a zero-length character vector removes the comment.

Usage

```
comment(x)
comment(x) <- value
```

Arguments

<code>x</code>	any R object.
<code>value</code>	a character vector, or <code>NULL</code> .

See Also

[attributes](#) and [attr](#) for other attributes.

Examples

```
x <- matrix(1:12, 3, 4)
comment(x) <- c("This is my very important data from experiment #0234",
               "Jun 5, 1998")

x
comment(x)
```

Comparison

Relational Operators

Description

Binary operators which allow the comparison of values in atomic vectors.

Usage

```
x < y
x > y
x <= y
x >= y
x == y
x != y
```

Arguments

`x, y` atomic vectors, symbols, calls, or other objects for which methods have been written.

Details

The binary comparison operators are generic functions: methods can be written for them individually or via the [Ops](#) group generic function. (See [Ops](#) for how dispatch is computed.)

Comparison of strings in character vectors is lexicographic within the strings using the collating sequence of the locale in use: see [locales](#). The collating sequence of locales such as ‘en_US’ is normally different from ‘C’ (which should use ASCII) and can be surprising. Beware of making *any* assumptions about the collation order: e.g. in Estonian Z comes between S and T, and collation is not necessarily character-by-character – in Danish aa sorts as a single letter, after z. In Welsh ng may or may not be a single sorting unit: if it is it follows g. Some platforms may not respect the locale and always sort in numerical order of the bytes in an 8-bit locale, or in Unicode code-point order for a UTF-8 locale (and may not sort in the same order for the same language in different character sets). Collation of non-letters (spaces, punctuation signs, hyphens, fractions and so on) is even more problematic.

Character strings can be compared with different marked encodings (see [Encoding](#)): they are translated to UTF-8 before comparison.

Raw vectors should not really be considered to have an order, but the numeric order of the byte representation is used.

At least one of `x` and `y` must be an atomic vector, but if the other is a list `R` attempts to coerce it to the type of the atomic vector: this will succeed if the list is made up of elements of length one that can be coerced to the correct type.

If the two arguments are atomic vectors of different types, one is coerced to the type of the other, the (decreasing) order of precedence being character, complex, numeric, integer, logical and raw.

Missing values (`NA`) and `NaN` values are regarded as non-comparable even to themselves, so comparisons involving them will always result in `NA`. Missing values can also result when character strings are compared and one is not valid in the current collation locale.

Language objects such as symbols and calls can only be used as operands for `==` and `!=`; the other comparisons signal an error when one of the operands is a language object. Currently language objects are deparsed to character strings before comparison. This can be inefficient and may not be what is really wanted. For equality comparisons `identical` is usually a better choice.

Value

A logical vector indicating the result of the element by element comparison. The elements of shorter vectors are recycled as necessary.

Objects such as arrays or time-series can be compared this way provided they are conformable.

S4 methods

These operators are members of the S4 `Compare` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops` group generic), with arguments `c(e1, e2)`.

Note

Do not use `==` and `!=` for tests, such as in `if` expressions, where you must get a single `TRUE` or `FALSE`. Unless you are absolutely sure that nothing unusual can happen, you should use the `identical` function instead.

For numerical and complex values, remember `==` and `!=` do not allow for the finite representation of fractions, nor for rounding error (“Why doesn’t R think these numbers are equal?” in *R FAQ*). Using `all.equal` with `identical` or `isTRUE` is almost always preferable; see the examples. (This also applies to the other comparison operators.)

These operators are sometimes called as functions as e.g. ``<`(x, y)`: see the description of how argument-matching is done in `Ops`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Collation of character strings is a complex topic. For an introduction see https://en.wikipedia.org/wiki/Collating_sequence. The *Unicode Collation Algorithm* (<https://unicode.org/reports/tr10/>) is likely to be increasingly influential. Where available R by default makes use of ICU (<https://icu.unicode.org/>) for collation (except in a C locale).

See Also

`Logic` on how to *combine* results of comparisons, i.e., logical vectors.

`factor` for the behaviour with factor arguments.

`Syntax` for operator precedence.

`capabilities` for whether ICU is available, and `icuSetCollate` to tune the string collation algorithm when it is.

Examples

```

x <- stats::rnorm(20)
x < 1
x[x > 0]

x1 <- 0.5 - 0.3i
x2 <- 0.3 - 0.1i
x1 == x2                # FALSE on most machines
isTRUE(all.equal(x1, x2)) # TRUE everywhere

# range of most 8-bit charsets, as well as of Latin-1 in Unicode
z <- c(32:126, 160:255)
x <- if (libiconv_info()$MBCS) {
  intToUtf8(z, multiple = TRUE)
} else rawToChar(as.raw(z), multiple = TRUE)
## by number
writeLines(strwrap(paste(x, collapse=" "), width = 60))
## by locale collation
writeLines(strwrap(paste(sort(x), collapse=" "), width = 60))

```

complex

*Complex Numbers and Basic Functionality***Description**

Basic functions which support complex arithmetic in R, in addition to the arithmetic operators $+$, $-$, $*$, $/$, and $^$.

Usage

```

complex(length.out = 0, real = numeric(), imaginary = numeric(),
         modulus = 1, argument = 0)
as.complex(x, ...)
is.complex(x)

```

```

Re(z)
Im(z)
Mod(z)
Arg(z)
Conj(z)

```

Arguments

<code>length.out</code>	numeric. Desired length of the output vector, inputs being recycled as needed.
<code>real</code>	numeric vector.
<code>imaginary</code>	numeric vector.
<code>modulus</code>	numeric vector.
<code>argument</code>	numeric vector.
<code>x</code>	an object, probably of mode <code>complex</code> .

`z` an object of mode `complex`, or one of a class for which a methods has been defined.

`...` further arguments passed to or from other methods.

Details

Complex vectors can be created with `complex`. The vector can be specified either by giving its length, its real and imaginary parts, or modulus and argument. (Giving just the length generates a vector of complex zeroes.)

`as.complex` attempts to coerce its argument to be of complex type: like `as.vector` it strips attributes including names. Since R version 4.4.0, `as.complex(x)` for “number-like” `x`, i.e., types `"logical"`, `"integer"`, and `"double"`, will always keep imaginary part zero, now also for NAs. Up to R versions 3.2.x, all forms of NA and NaN were coerced to a complex NA, i.e., the `NA_complex_` constant, for which both the real and imaginary parts are NA. Since R 3.3.0, typically only objects which are NA in parts are coerced to complex NA, but others with NaN parts, are *not*. As a consequence, complex arithmetic where only NaNs (but no NAs) are involved typically will *not* give complex NA but complex numbers with real or imaginary parts of NaN. All of these many different complex numbers fulfill `is.na(.)` but only one of them is identical to `NA_complex_`.

Note that `is.complex` and `is.numeric` are never both TRUE.

The functions `Re`, `Im`, `Mod`, `Arg` and `Conj` have their usual interpretation as returning the real part, imaginary part, modulus, argument and complex conjugate for complex values. The modulus and argument are also called the *polar coordinates*. If $z = x + iy$ with real x and y , for $r = \text{Mod}(z) = \sqrt{x^2 + y^2}$, and $\phi = \text{Arg}(z)$, $x = r \cos(\phi)$ and $y = r \sin(\phi)$. They are all [internal generic primitive](#) functions: methods can be defined for them individually or *via* the [Complex](#) group generic.

In addition to the arithmetic operators (see [Arithmetic](#)) `+`, `-`, `*`, `/`, and `^`, the elementary trigonometric, logarithmic, exponential, square root and hyperbolic functions are implemented for complex values.

Matrix multiplications (`%*%`, `crossprod`, `tcrossprod`) are also defined for complex matrices (`matrix`), and so are `solve`, `eigen` or `svd`.

Internally, complex numbers are stored as a pair of [double](#) precision numbers, either or both of which can be NaN (including NA, see `NA_complex_` and above) or plus or minus infinity.

S4 methods

`as.complex` is primitive and can have S4 methods set.

`Re`, `Im`, `Mod`, `Arg` and `Conj` constitute the S4 group generic [Complex](#) and so S4 methods can be set for them individually or *via* the group generic.

Note

Operations and functions involving complex NaN mostly rely on the C library’s handling of ‘double complex’ arithmetic, which typically returns `complex(re=NaN, im=NaN)` (but we have not seen a guarantee for that). For `+` and `-`, R’s own handling works strictly “coordinate wise”.

Operations involving complex NA, i.e., `NA_complex_`, return `NA_complex_`.

Only since R version 4.4.0, `as.complex("1i")` gives `1i`, it returned `NA_complex_` with a warning, previously.

See Also

`Arithmetic`; `polyroot` finds all n complex roots of a polynomial of degree n .

Examples

```
require(graphics)

0i ^ (-3:3)

matrix(1i^ (-6:5), nrow = 4) #- all columns are the same
0 ^ 1i # a complex NaN

## create a complex normal vector
z <- complex(real = stats::rnorm(100), imaginary = stats::rnorm(100))
## or also (less efficiently):
z2 <- 1:2 + 1i*(8:9)

## The Arg(.) is an angle:
zz <- (rep(1:4, length.out = 9) + 1i*(9:1))/10
zz.shift <- complex(modulus = Mod(zz), argument = Arg(zz) + pi)
plot(zz, xlim = c(-1,1), ylim = c(-1,1), col = "red", asp = 1,
     main = expression(paste("Rotation by ", " ", pi == 180^o)))
abline(h = 0, v = 0, col = "blue", lty = 3)
points(zz.shift, col = "orange")

## as.complex(<some NA>): numbers keep Im = 0:
NAs <- vapply(list(NA, NA_integer_, NA_real_, NA_character_, NA_complex_),
              as.complex, 0+0i)
stopifnot(is.na(NAs), is.na(Re(NAs))) # has always been true
showC <- function(z) noquote(paste0("(", Re(z), ",", Im(z), ")"))
showC(NAs)
Im(NAs) # [0 0 0 NA NA] \\ in R <= 4.3.x was [NA NA 0 NA NA]
stopifnot(Im(NAs)[1:3] == 0)
stopifnot(Im(NA_real_ + 0i) == 0) # has always been true

## The exact result of this *depends* on the platform, compiler, math-library:
(NpNA <- NaN + NA_complex_) ; str(NpNA) # *behaves* as 'cplx NA' ..
stopifnot(is.na(NpNA), is.na(NA_complex_), is.na(Re(NA_complex_)), is.na(Im(NA_complex_)))
showC(NpNA) # but does not always show '(NaN,NA)'
## and this is not TRUE everywhere:
identical(NpNA, NA_complex_)
showC(NA_complex_) # always == (NA,NA)
```

Description

These functions provide a mechanism for handling unusual conditions, including errors and warnings.

Usage

```
tryCatch(expr, ..., finally)
withCallingHandlers(expr, ...)
globalCallingHandlers(...)

signalCondition(cond)

simpleCondition(message, call = NULL)
simpleError      (message, call = NULL)
simpleWarning    (message, call = NULL)
simpleMessage    (message, call = NULL)

errorCondition(message, ..., class = NULL, call = NULL)
warningCondition(message, ..., class = NULL, call = NULL)
messageCondition(message, ..., class = NULL, call = NULL)

## S3 method for class 'condition'
as.character(x, ...)
## S3 method for class 'error'
as.character(x, ...)
## S3 method for class 'condition'
print(x, ...)
## S3 method for class 'restart'
print(x, ...)

conditionCall(c)
## S3 method for class 'condition'
conditionCall(c)
conditionMessage(c)
## S3 method for class 'condition'
conditionMessage(c)

withRestarts(expr, ...)

computeRestarts(cond = NULL)
findRestart(name, cond = NULL)
invokeRestart(r, ...)
tryInvokeRestart(r, ...)
invokeRestartInteractively(r)

isRestart(x)
restartDescription(r)
restartFormals(r)

suspendInterrupts(expr)
allowInterrupts(expr)
```

```
.signalSimpleWarning(msg, call)
.handleSimpleError(h, msg, call)
.tryResumeInterrupt()
```

Arguments

<code>c</code>	a condition object.
<code>call</code>	call expression.
<code>cond</code>	a condition object.
<code>expr</code>	expression to be evaluated.
<code>finally</code>	expression to be evaluated before returning or exiting.
<code>h</code>	function.
<code>message</code>	character string.
<code>msg</code>	character string.
<code>name</code>	character string naming a restart.
<code>r</code>	restart object.
<code>x</code>	object.
<code>class</code>	character string naming a condition class.
<code>...</code>	additional arguments; see details below.

Details

The condition system provides a mechanism for signaling and handling unusual conditions, including errors and warnings. Conditions are represented as objects that contain information about the condition that occurred, such as a message and the call in which the condition occurred. Currently conditions are S3-style objects, though this may eventually change.

Conditions are objects inheriting from the abstract class `condition`. Errors and warnings are objects inheriting from the abstract subclasses `error` and `warning`. The class `simpleError` is the class used by `stop` and all internal error signals. Similarly, `simpleWarning` is used by `warning`, and `simpleMessage` is used by `message`. The constructors by the same names take a string describing the condition as argument and an optional call. The functions `conditionMessage` and `conditionCall` are generic functions that return the message and call of a condition.

The function `errorCondition` can be used to construct error conditions of a particular class with additional fields specified as the `...` argument. `messageCondition` and `warningCondition` are analogous for messages and warnings, respectively.

Conditions are signaled by `signalCondition`. In addition, the `stop` and `warning` functions have been modified to also accept condition arguments.

The function `tryCatch` evaluates its expression argument in a context where the handlers provided in the `...` argument are available. The `finally` expression is then evaluated in the context in which `tryCatch` was called; that is, the handlers supplied to the current `tryCatch` call are not active when the `finally` expression is evaluated.

Handlers provided in the `...` argument to `tryCatch` are established for the duration of the evaluation of `expr`. If no condition is signaled when evaluating `expr` then `tryCatch` returns the value of the expression.

If a condition is signaled while evaluating `expr` then established handlers are checked, starting with the most recently established ones, for one matching the class of the condition. When several

handlers are supplied in a single `tryCatch` then the first one is considered more recent than the second. If a handler is found then control is transferred to the `tryCatch` call that established the handler, the handler found and all more recent handlers are disestablished, the handler is called with the condition as its argument, and the result returned by the handler is returned as the value of the `tryCatch` call.

Calling handlers are established by `withCallingHandlers`. If a condition is signaled and the applicable handler is a calling handler, then the handler is called by `signalCondition` in the context where the condition was signaled but with the available handlers restricted to those below the handler called in the handler stack. If the handler returns, then the next handler is tried; once the last handler has been tried, `signalCondition` returns `NULL`.

`globalCallingHandlers` establishes calling handlers globally. These handlers are only called as a last resort, after the other handlers dynamically registered with `withCallingHandlers` have been invoked. They are called before the `error` global option (which is the legacy interface for global handling of errors). Registering the same handler multiple times moves that handler on top of the stack, which ensures that it is called first. Global handlers are a good place to define a general purpose logger (for instance saving the last error object in the global workspace) or a general recovery strategy (e.g. installing missing packages via the `retry_loadNamespace` restart).

Like `withCallingHandlers` and `tryCatch`, `globalCallingHandlers` takes named handlers. Unlike these functions, it also has an `options`-like interface: you can establish handlers by passing a single list of named handlers. To unregister all global handlers, supply a single `'NULL'`. The list of deleted handlers is returned invisibly. Finally, calling `globalCallingHandlers` without arguments returns the list of currently established handlers, visibly.

User interrupts signal a condition of class `interrupt` that inherits directly from class `condition` before executing the default interrupt action.

Restarts are used for establishing recovery protocols. They can be established using `withRestarts`. One pre-established restart is an `abort` restart that represents a jump to top level.

`findRestart` and `computeRestarts` find the available restarts. `findRestart` returns the most recently established restart of the specified name. `computeRestarts` returns a list of all restarts. Both can be given a condition argument and will then ignore restarts that do not apply to the condition.

`invokeRestart` transfers control to the point where the specified restart was established and calls the restart's handler with the arguments, if any, given as additional arguments to `invokeRestart`. The restart argument to `invokeRestart` can be a character string, in which case `findRestart` is used to find the restart. If no restart is found, an error is thrown.

`tryInvokeRestart` is a variant of `invokeRestart` that returns silently when the restart cannot be found with `findRestart`. Because a condition of a given class might be signalled with arbitrary protocols (error, warning, etc), it is recommended to use this permissive variant whenever you are handling conditions signalled from a foreign context. For instance, invocation of a `"muffleWarning"` restart should be optional because the warning might have been signalled by the user or from a different package with the `stop` or `message` protocols. Only use `invokeRestart` when you have control of the signalling context, or when it is a logical error if the restart is not available.

New restarts for `withRestarts` can be specified in several ways. The simplest is in `name = function` form where the function is the handler to call when the restart is invoked. Another simple variant is as `name = string` where the string is stored in the `description` field of the restart object returned by `findRestart`; in this case the handler ignores its arguments and returns `NULL`. The most flexible form of a restart specification is as a list that can include several fields, including `handler`, `description`, and `test`. The `test` field should contain a function of one

argument, a condition, that returns TRUE if the restart applies to the condition and FALSE if it does not; the default function returns TRUE for all conditions.

One additional field that can be specified for a restart is `interactive`. This should be a function of no arguments that returns a list of arguments to pass to the restart handler. The list could be obtained by interacting with the user if necessary. The function `invokeRestartInteractively` calls this function to obtain the arguments to use when invoking the restart. The default `interactive` method queries the user for values for the formal arguments of the handler function.

Interrupts can be suspended while evaluating an expression using `suspendInterrupts`. Subexpression can be evaluated with interrupts enabled using `allowInterrupts`. These functions can be used to make sure cleanup handlers cannot be interrupted.

`.signalSimpleWarning`, `.handleSimpleError`, and `.tryResumeInterrupt` are used internally and should not be called directly.

References

The `tryCatch` mechanism is similar to Java error handling. Calling handlers are based on Common Lisp and Dylan. Restarts are based on the Common Lisp restart mechanism.

See Also

`stop` and `warning` signal conditions, and `try` is essentially a simplified version of `tryCatch`. `assertCondition` in package **tools** *tests* that conditions are signalled and works with several of the above handlers.

Examples

```
tryCatch(1, finally = print("Hello"))
e <- simpleError("test error")
## Not run:
  stop(e)
  tryCatch(stop(e), finally = print("Hello"))
  tryCatch(stop("fred"), finally = print("Hello"))

## End(Not run)
tryCatch(stop(e), error = function(e) e, finally = print("Hello"))
tryCatch(stop("fred"), error = function(e) e, finally = print("Hello"))
withCallingHandlers({ warning("A"); 1+2 }, warning = function(w) {})
## Not run:
  { withRestarts(stop("A"), abort = function() {}); 1 }

## End(Not run)
withRestarts(invokeRestart("foo", 1, 2), foo = function(x, y) {x + y})

##--> More examples are part of
##--> demo(error.catching)
```

Description

`conflicts` reports on objects that exist with the same name in two or more places on the [search path](#), usually because an object in the user's workspace or a package is masking a system object of the same name. This helps discover unintentional masking.

Usage

```
conflicts(where = search(), detail = FALSE)
```

Arguments

<code>where</code>	A subset of the search path, by default the whole search path.
<code>detail</code>	If <code>TRUE</code> , give the masked or masking functions for all members of the search path.

Value

If `detail = FALSE`, a character vector of masked objects. If `detail = TRUE`, a list of character vectors giving the masked or masking objects in that member of the search path. Empty vectors are omitted.

Examples

```
lm <- 1:3
conflicts(, TRUE)
## gives something like
# $.GlobalEnv
# [1] "lm"
#
# $package:base
# [1] "lm"

## Remove things from your "workspace" that mask others:
remove(list = conflicts(detail = TRUE)$GlobalEnv)
```

connections

Functions to Manipulate Connections (Files, URLs, ...)

Description

Functions to create, open and close connections, i.e., “generalized files”, such as possibly compressed files, URLs, pipes, etc.

Usage

```
file(description = "", open = "", blocking = TRUE,
      encoding = getOption("encoding"), raw = FALSE,
      method = getOption("url.method", "default"))

url(description, open = "", blocking = TRUE,
     encoding = getOption("encoding"),
     method = getOption("url.method", "default"),
```

```

    headers = NULL)

gzfile(description, open = "", encoding = getOption("encoding"),
        compression = 6)

bzfile(description, open = "", encoding = getOption("encoding"),
        compression = 9)

xzfile(description, open = "", encoding = getOption("encoding"),
        compression = 6)

zstdfile(description, open = "", encoding = getOption("encoding"),
        compression = 9)

unz(description, filename, open = "", encoding = getOption("encoding"))

pipe(description, open = "", encoding = getOption("encoding"))

fifo(description, open = "", blocking = FALSE,
      encoding = getOption("encoding"))

socketConnection(host = "localhost", port, server = FALSE,
                 blocking = FALSE, open = "a+",
                 encoding = getOption("encoding"),
                 timeout = getOption("timeout"),
                 options = getOption("socketOptions"))

serverSocket(port)

socketAccept(socket, blocking = FALSE, open = "a+",
            encoding = getOption("encoding"),
            timeout = getOption("timeout"),
            options = getOption("socketOptions"))

open(con, ...)
## S3 method for class 'connection'
open(con, open = "r", blocking = TRUE, ...)

close(con, ...)
## S3 method for class 'connection'
close(con, type = "rw", ...)

flush(con)

isOpen(con, rw = "")
isIncomplete(con)

socketTimeout(socket, timeout = -1)

```

Arguments

`description` character string. A description of the connection: see ‘Details’.

<code>open</code>	character string. A description of how to open the connection (if it should be opened initially). See section ‘Modes’ for possible values.
<code>blocking</code>	logical. See the ‘Blocking’ section.
<code>encoding</code>	the name of the encoding to be assumed. See the ‘Encoding’ section.
<code>raw</code>	logical. If true, a ‘raw’ interface is used which will be more suitable for arguments which are not regular files, e.g. character devices. This suppresses the check for a compressed file when opening for text-mode reading, and asserts that the ‘file’ may not be seekable.
<code>method</code>	character string, partially matched to <code>c("default", "internal", "wininet", "libcurl")</code> : see ‘Details’.
<code>headers</code>	named character vector of HTTP headers to use in HTTP requests. It is ignored for non-HTTP URLs. The <code>User-Agent</code> header, coming from the <code>HTTPUserAgent</code> option (see options) is used as the first header, automatically.
<code>compression</code>	integer in 0–9 (1–19 for <code>zstdfile</code>). The amount of compression to be applied when writing, from minimal to maximal available. For <code>xzfile</code> and <code>zstdfile</code> can also be negative: see the ‘Compression’ section.
<code>timeout</code>	numeric: the timeout (in seconds) to be used for this connection. Beware that some OSes may treat very large values as zero: however the POSIX standard requires values up to 31 days to be supported.
<code>options</code>	optional character vector with options. Currently only <code>"no-delay"</code> is supported on TCP sockets.
<code>filename</code>	a filename within a zip file.
<code>host</code>	character string. Host name for the port.
<code>port</code>	integer. The TCP port number.
<code>server</code>	logical. Should the socket be a client or a server?
<code>socket</code>	a server socket listening for connections.
<code>con</code>	a connection.
<code>type</code>	character string. Currently ignored.
<code>rw</code>	character string. Empty or <code>"read"</code> or <code>"write"</code> , partial matches allowed.
<code>...</code>	arguments passed to or from other methods.

Details

The first eleven functions create connections. By default the connection is not opened (except for a socket connection created by `socketConnection` or `socketAccept` and for server socket connection created by `serverSocket`), but may be opened by setting a non-empty value of argument `open`.

For `file` the description is a path to the file to be opened (when [tilde expansion](#) is done) or a complete URL (when it is the same as calling `url`), or `"` (the default) or `"clipboard"` (see the ‘Clipboard’ section). Use `"stdin"` to refer to the C-level ‘standard input’ of the process (which need not be connected to anything in a console or embedded version of R, and is not in RGui on Windows). See also `stdin()` for the subtly different R-level concept of `stdin`. See `nullfile()` for a platform-independent way to get filename of the null device.

For `url` the description is a complete URL including scheme (such as `"http://"`, `"https://"`, `"ftp://"` or `"file://"`). Method `"internal"` is that available since connections were introduced but now mainly defunct. Method `"wininet"` is only available on Windows (it uses

the WinINET functions of that OS) and method "libcurl" (using the library of that name: <https://curl.se/libcurl/>) is nowadays required but was optional on Windows before R 4.2.0. Method "default" currently uses method "internal" for 'file://' URLs and "libcurl" for all others. Which methods support which schemes has varied by R version – currently "internal" supports only 'file://'; "wininet" supports 'file://', 'http://' and 'https://'. Proxies and user credentials can be specified: see [download.file](#).

For `gzfile` the description is the path to a file compressed by `gzip`: it can also open for reading uncompressed files and those compressed by `bzip2`, `xz`, `lzma` or (if R was built to support it) `zstd`.

For `bzfile` the description is the path to a file compressed by `bzip2`.

For `xzfile` the description is the path to a file compressed by `xz` (<https://en.wikipedia.org/wiki/Xz>) or (for reading only) `lzma` (<https://en.wikipedia.org/wiki/LZMA>).

For `zstdfile` the description is the path to a file compressed by `zstd` (<https://en.wikipedia.org/wiki/Zstd>): support is optional when R is built.

`unz` reads (only) single files within zip files, in binary mode. The description is the full path to the zip file, with '.zip' extension if required.

For `pipe` the description is the command line to be piped to or from. This is run in a shell, on Windows that specified by the `COMSPEC` environment variable.

For `fifo` the description is the path of the fifo. (Support for `fifo` connections is optional but they are available on most Unix platforms and on Windows.)

The intention is that `file` and `gzfile` can be used generally for text input (from files, 'http://' and 'https://' URLs) and binary input respectively.

`open`, `close` and `seek` are generic functions: the following applies to the methods relevant to connections.

`open` opens a connection. In general functions using connections will open them if they are not open, but then close them again, so to leave a connection open call `open` explicitly.

`close` closes and destroys a connection. This will happen automatically in due course (with a warning) if there is no longer an R object referring to the connection.

`flush` flushes the output stream of a connection open for write/append (where implemented, currently for file and clipboard connections, `stdout` and `stderr`).

If for a `file` or (on most platforms) a `fifo` connection the description is "", the file/fifo is immediately opened (in "w+" mode unless `open = "w+b"` is specified) and unlinked from the file system. This provides a temporary file/fifo to write to and then read from.

`socketConnection(server=TRUE)` creates a new temporary server socket listening on the given port. As soon as a new socket connection is accepted on that port, the server socket is automatically closed. `serverSocket` creates a listening server socket which can be used for accepting multiple socket connections by `socketAccept`. To stop listening for new connections, a server socket needs to be closed explicitly by `close`.

`socketConnection` and `socketAccept` support setting of socket-specific options. Currently only "no-delay" is implemented which enables the `TCP_NODELAY` socket option, causing the socket to flush send buffers immediately (instead of waiting to collect all output before sending). This option is useful for protocols that need fast request/response turn-around times.

`socketTimeout` sets connection timeout of a socket connection. A negative `timeout` can be given to query the old value.

Value

`file`, `pipe`, `fifo`, `url`, `gzfile`, `bzfile`, `xzfile`, `zstdfile`, `unz`, `socketConnection`, `socketAccept` and `serverSocket` return a connection object which inherits from class "connection" and has a first more specific class.

`open` and `flush` return `NULL`, invisibly.

`close` returns either `NULL` or an integer status, invisibly. The status is from when the connection was last closed and is available only for some types of connections (e.g., pipes, files and fifos): typically zero values indicate success. Negative values will result in a warning; if writing, these may indicate write failures and should not be ignored. Connections should be closed explicitly when finished with to avoid wasting resources and to reduce the risk that some buffered data in output connections would be lost (see `on.exit()` for how to run code also in case of error).

`isOpen` returns a logical value, whether the connection is currently open.

`isIncomplete` returns a logical value, whether the last read attempt from a non-blocking connection provided no data (currently no data from a socket or an unterminated line in `readLines()`), or for an output text connection whether there is unflushed output. See example below.

`socketTimeout` returns the old timeout value of a socket connection.

URLs

`url` and `file` support URL schemes 'file://', 'http://', 'https://' and 'ftp://'.

`method = "libcurl"` allows more schemes: exactly which schemes is platform-dependent (see `libcurlVersion()`), but all platforms will support 'https://' and most platforms will support 'ftps://'.

Support for the 'ftp://' scheme by the "internal" method was deprecated in R 4.1.1 and removed in R 4.2.0.

Most methods do not percent-encode special characters such as spaces in 'http://' URLs (see `URLencode()`), but it seems the "wininet" method does.

A note on 'file://' URLs (which are handled by the same internal code irrespective of argument `method`). The most general form (from RFC1738) is 'file://host/path/to/file', but R only accepts the form with an empty `host` field referring to the local machine.

On a Unix-alike, this is then 'file:///path/to/file', where 'path/to/file' is relative to '/'. So although the third slash is strictly part of the specification not part of the path, this can be regarded as a way to specify the file '/path/to/file'. It is not possible to specify a relative path using a file URL.

In this form the path is relative to the root of the filesystem, not a Windows concept. The standard form on Windows is 'file:///d:/R/repos': for compatibility with earlier versions of R and Unix versions, any other form is parsed as R as 'file://' plus `path_to_file`. Also, backslashes are accepted within the path even though RFC1738 does not allow them.

No attempt is made to decode a percent-encoded 'file:' URL: call `URLdecode` if necessary.

All the methods attempt to follow redirected HTTP and HTTPS URLs.

Server-side cached data is always accepted.

Function `download.file` and several contributed packages provide more comprehensive facilities to download from URLs.

Modes

Possible values for the argument `open` are

"r" or "rt" Open for reading in text mode.
 "w" or "wt" Open for writing in text mode.
 "a" or "at" Open for appending in text mode.
 "rb" Open for reading in binary mode.
 "wb" Open for writing in binary mode.
 "ab" Open for appending in binary mode.
 "r+", "r+b" Open for reading and writing.
 "w+", "w+b" Open for reading and writing, truncating file initially.
 "a+", "a+b" Open for reading and appending.

Not all modes are applicable to all connections: for example URLs can only be opened for reading. Only file and socket connections can be opened for both reading and writing. An unsupported mode is usually silently substituted.

If a file or fifo is created on a Unix-alike, its permissions will be the maximal allowed by the current setting of `umask` (see [Sys.umask](#)).

For many connections there is little or no difference between text and binary modes. For file-like connections on Windows, translation of line endings (between LF and CRLF) is done in text mode only (but text read operations on connections such as [readLines](#), [scan](#) and [source](#) work for any form of line ending). Various R operations are possible in only one of the modes: for example [pushBack](#) is text-oriented and is only allowed on connections open for reading in text mode, and binary operations such as [readBin](#), [load](#) and [save](#) can only be done on binary-mode connections.

The mode of a connection is determined when actually opened, which is deferred if `open = ""` is given (the default for all but socket connections). An explicit call to `open` can specify the mode, but otherwise the mode will be "r". (`gzfile`, `bzfile`, `xzfile` and `zstdfile` connections are exceptions, as the compressed file always has to be opened in binary mode and no conversion of line-endings is done even on Windows, so the default mode is interpreted as "rb".) Most operations that need write access or text-only or binary-only mode will override the default mode of a non-yet-open connection.

Append modes need to be considered carefully for compressed-file connections. They do **not** produce a single compressed stream on the file, but rather append a new compressed stream to the file. Readers may or may not read beyond end of the first stream: currently R does so for `gzfile`, `bzfile`, `xzfile`, `zstdfile` and [gzcon](#) connections.

Compression

R supports `gzip`, `bzip2`, `zstd` and `xz` compression (also read-only support for its precursor, `lzma` compression).

For reading, the type of compression (if any) can be determined from the first few bytes of the file. Thus for `file(raw = FALSE)` connections, if `open` is "", "r" or "rt" the connection can read any of the compressed file types as well as uncompressed files. (Using "rb" will allow compressed files to be read byte-by-byte.) Similarly, `gzfile` connections can read any of the forms of compression and uncompressed files in any read mode.

(The type of compression is determined when the connection is created if `open` is unspecified and a file of that name exists. If the intention is to open the connection to write a file with a *different* form of compression under that name, specify `open = "w"` when the connection is created or [unlink](#) the file before creating the connection.)

For write-mode connections, `compress` specifies how hard the compressor works to minimize the file size, and higher values need more CPU time and more working memory (up to ca 800Mb for

`xzfile(compress = 9)`). For `xzfile` negative values of `compress` correspond to adding the `xz` argument `'-e'`: this takes more time (double?) to compress but may achieve (slightly) better compression. The default (6) has good compression and modest (100Mb memory) usage: but if you are using `xz` compression you are probably looking for high compression.

For `zstd` negative numbers correspond to the `'--fast='` compression levels which are faster but yield slightly worse compression.

Choosing the type of compression involves tradeoffs: `gzip`, `bzip2` and `xz` are successively less widely supported, need more resources for both compression and decompression, and achieve more compression (although individual files may buck the general trend). Typical experience is that `bzip2` compression is 15% better on text files than `gzip` compression, and `xz` with maximal compression 30% better. The experience with R `save` files is similar, but on some large `'.rda'` files `xz` compression is much better than the other two. With current computers decompression times even with `compress = 9` are typically modest and reading compressed files is usually faster than uncompressed ones because of the reduction in disc activity.

The `zstd` compression support is currently optional and will be only included if the underlying library is present at build time. All related functions will return an error if the support is not present. It typically offers slightly worse compression than `xz`, but is orders of magnitude faster to compress.

Encoding

The encoding of the input/output stream of a connection can be specified by name in the same way as it would be given to `iconv`: see that help page for how to find out what encoding names are recognized on your platform. Additionally, `"` and `"native.enc"` both mean the 'native' encoding, that is the internal encoding of the current locale and hence no translation is done.

When writing to a text connection, the connections code always assumes its input is in native encoding, so e.g. `writeLines` has to convert text to native encoding. The native encoding is UTF-8 on most systems (since R 4.2 also on recent Windows) and can represent all characters. `writeLines` does not do the conversion when `useBytes=TRUE` (for expert use only, only useful on systems with native encoding other than UTF-8), but the connections code still behaves as if the text was in native encoding, so any attempt to convert encoding (`encoding` argument other than `"` and `"native.enc"`) in connections will produce incorrect results.

When reading from a text connection, the connections code re-encodes the input to native encoding (from the encoding given by the `encoding` argument). On systems where UTF-8 is not the native encoding, one can read text not representable in the native encoding using `readLines` and `scan` by providing them with an unopened connection that has been created with the `encoding` argument specifying the input encoding. `readLines` and `scan` would then instruct the connections code to convert the text to UTF-8 (instead of native encoding) and they will return it marked (aka declared, see [Encoding](#)) as `"UTF-8"`. Finally and for expert use only, one may disable re-encoding of input by specifying `"` or `"native.enc"` as `encoding` for the connection, but then mark the text as being `"UTF-8"` or `"latin1"` via the `encoding` argument of `readLines` and `scan`.

Re-encoding only works for connections in text mode: reading from a connection with re-encoding specified in binary mode will read the stream of bytes, but mixing text and binary mode reads (e.g., mixing calls to `readLines` and `readChar`) is likely to lead to incorrect results.

The encodings `"UCS-2LE"` and `"UTF-16LE"` are treated specially, as they are appropriate values for Windows 'Unicode' text files. If the first two bytes are the Byte Order Mark `0xFEFF` then these are removed as some implementations of `iconv` do not accept BOMs. Note that whereas most implementations will handle BOMs using encoding `"UCS-2"` and choose the appropriate byte order, some (including earlier versions of `glibc`) will not. There is a subtle distinction between `"UTF-16"` and `"UCS-2"` (see <https://en.wikipedia.org/wiki/UTF-16>): the use of

characters in the ‘Supplementary Planes’ which need surrogate pairs is very rare so "UCS-2LE" is an appropriate first choice (as it is more widely implemented).

The encoding "UTF-8-BOM" is accepted for reading and will remove a Byte Order Mark if present (which it often is for files and webpages generated by Microsoft applications). If a BOM is required (it is not recommended) when writing it should be written explicitly, e.g. by `writeChar("\ufeff", con, eos = NULL)` or `writeBin(as.raw(c(0xef, 0xbb, 0xbf)), binary_con)`

Encoding names "utf8", "mac" and "macroman" are not portable, and not supported on all current R platforms. "UTF-8" is portable and "macintosh" is the official (and most widely supported) name for ‘Mac Roman’. (R maps "utf8" to "UTF-8" internally.)

Requesting a conversion that is not supported is an error, reported when the connection is opened. Exactly what happens when the requested translation cannot be done for invalid input is in general undocumented. On output the result is likely to be that up to the error, with a warning. On input, it will most likely be all or some of the input up to the error.

It may be possible to deduce the current native encoding from `Sys.getlocale("LC_CTYPE")`, but not all OSes record it.

Blocking

Whether or not the connection blocks can be specified for file, url (default yes), fifo and socket connections (default not).

In blocking mode, functions using the connection do not return to the R evaluator until the read/write is complete. In non-blocking mode, operations return as soon as possible, so on input they will return with whatever input is available (possibly none) and for output they will return whether or not the write succeeded.

The function `readLines` behaves differently in respect of incomplete last lines in the two modes: see its help page.

Even when a connection is in blocking mode, attempts are made to ensure that it does not block the event loop and hence the operation of GUI parts of R. These do not always succeed, and the whole R process will be blocked during a DNS lookup on Unix, for example.

Most blocking operations on HTTP/FTP URLs and on sockets are subject to the timeout set by `options("timeout")`. Note that this is a timeout for no response, not for the whole operation. The timeout is set at the time the connection is opened (more precisely, when the last connection of that type – ‘http:’, ‘ftp:’ or socket – was opened).

Fifos

Fifos default to non-blocking. That follows S version 4 and is probably most natural, but it does have some implications. In particular, opening a non-blocking fifo connection for writing (only) will fail unless some other process is reading on the fifo.

Opening a fifo for both reading and writing (in any mode: one can only append to fifos) connects both sides of the fifo to the R process, and provides an similar facility to `file()`.

Clipboard

`file` can be used with `description = "clipboard"` in mode "r" only. This reads the X11 primary selection (see <https://specifications.freedesktop.org/clipboard/>), which can also be specified as "X11_primary" and the secondary selection as "X11_secondary". On most systems the clipboard selection (that used by ‘Copy’ from an ‘Edit’ menu) can be specified as "X11_clipboard".

When a clipboard is opened for reading, the contents are immediately copied to internal storage in the connection.

Unix users wishing to *write* to one of the X11 selections may be able to do so via `xclip` (<https://github.com/astrand/xclip>) or `xsel` (<https://www.vergenet.net/~conrad/software/xsel/>), for example by `pipe("xclip -i", "w")` for the primary selection.

macOS users can use `pipe("pbpaste")` and `pipe("pbcopy", "w")` to read from and write to that system's clipboard.

File paths

In most cases these are translated to the native encoding.

The exceptions are `file` and `pipe` on Windows, where a description which is marked as being in UTF-8 is passed to Windows as a 'wide' character string. This allows files with names not in the native encoding to be opened on file systems which use Unicode file names (such as NTFS but not FAT32).

'ftp://' URLs

Most modern browsers do not support such URLs, and 'https://' ones are much preferred for use in R.

It is intended that R will continue to allow such URLs for as long as `libcurl` does, but as they become rarer this is increasingly untested. What 'protocols' the version of `libcurl` being used supports can be seen by calling `libcurlVersion()`.

Number of connections

There is a limit on the number of connections which can be allocated (not necessarily open) at any one time. It is good practice to close connections when finished with, but if necessary garbage-collection will be invoked to close those connections without any R object referring to them.

The default limit is 128 (including the three terminal connections, `stdin`, `stdout` and `stderr`). This can be increased when R is started using the option '`--max-connections=N`', where the maximum allowed value is 4096.

However, many types of connections use other resources which are themselves limited. Notably on Unix, 'file descriptors' which by default are per-process limited: this limits the number of connections using files, pipes and fifos. (The default limit is 256 on macOS (and Solaris) but 1024 on Linux. The limit can be raised in the shell used to launch R, for example by `ulimit -n`.) File descriptors are used for many other purposes including dynamically loading DSO/DLLs (see [dyn.load](#)) which may use up to 60% of the limit.

Windows has a default limit of 512 open C file streams: these are used by at least `file`, `gzfile`, `bzfile`, `xzfile`, `zstdfile`, `pipe`, `url` and `unz` connections applied to files (rather than URLs).

Package **parallel**'s `makeCluster` uses socket connections to communicate with the worker processes, one per worker.

Note

R's connections are modelled on those in S version 4 (Chambers 1998). However R goes well beyond the S model, for example in output text connections and URL, compressed and socket connections. The default open mode in R is "`r`" except for socket connections. This differs from S, where it is the equivalent of "`r+`", known as "`*`".

On (historic) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 byte output limit on the length of a line for text output on `fifo`, `gzfile`, `bzfile`, `xzfile` and `zstdfile` connections: longer lines will be truncated with a warning.

To flush output to the Windows and macOS consoles, see `flush.console`.

Examples

```
zzfil <- tempfile(fileext=".data")
zz <- file(zzfil, "w") # open an output file connection
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
cat("One more line\n", file = zz)
close(zz)
readLines(zzfil)
unlink(zzfil)
```

```
zzfil <- tempfile(fileext=".gz")
zz <- gzfile(zzfil, "w") # compressed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile(zzfil))
close(zz)
unlink(zzfil)
zz # an invalid connection
```

```
zzfil <- tempfile(fileext=".bz2")
zz <- bzfile(zzfil, "w") # bzip2-ed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
zz # print() method: invalid connection
print(readLines(zz <- bzfile(zzfil)))
close(zz)
unlink(zzfil)
```

con <- socketConnection(port = 79, blocking = TRUE)
writeLines(paste0(system("whoami", intern = TRUE), "\r"), con)
gsub(" *$", "", readLines(con))
close(con)

## End(Not run)

## Not run:
## Two R processes communicating via non-blocking sockets
# R process 1
con1 <- socketConnection(port = 6011, server = TRUE)
writeLines(LETTERS, con1)
close(con1)

# R process 2
con2 <- socketConnection(Sys.info()["nodename"], port = 6011)
# as non-blocking, may need to loop for input
readLines(con2)
while(isIncomplete(con2)) {
  Sys.sleep(1)
  z <- readLines(con2)
  if(length(z)) print(z)
}
close(con2)

## examples of use of encodings
# write a file in UTF-8
cat(x, file = (con <- file("foo", "w", encoding = "UTF-8"))); close(con)
# read a 'Windows Unicode' file
A <- read.table(con <- file("students", encoding = "UCS-2LE")); close(con)

## End(Not run)
```

Constants

Built-in Constants

Description

Constants built into R.

Usage

```
LETTERS
letters
month.abb
month.name
pi
```

Details

R has a small number of built-in constants.

The following constants are available:

- `LETTERS`: the 26 upper-case letters of the Roman alphabet;
- `letters`: the 26 lower-case letters of the Roman alphabet;
- `month.abb`: the three-letter abbreviations for the English month names;
- `month.name`: the English names for the months of the year;
- `pi`: the ratio of the circumference of a circle to its diameter.

These are implemented as variables in the base namespace taking appropriate values.

References

See Also

[data](#), [DateTimeClasses](#).

[Quotes](#) for the parsing of character constants, [NumericConstants](#) for numeric constants.

Examples

```
## John Machin (ca 1706) computed pi to over 100 decimal places
## using the Taylor series expansion of the second term of
pi - 4*(4*atan(1/5) - atan(1/239))

## months in English
month.name
## months in your current locale
format(ISOdate(2000, 1:12, 1), "%B")
format(ISOdate(2000, 1:12, 1), "%b")
```

contributors

R Project Contributors

Description

The R Who-is-who, describing who made significant contributions to the development of R.

Usage

```
contributors()
```

Description

These are the basic control-flow constructs of the R language. They function in much the same way as control statements in any Algol-like language. They are all [reserved](#) words.

Usage

```
if(cond) expr
if(cond) cons.expr else alt.expr

for(var in seq) expr
while(cond) expr
repeat expr
break
next

x %||% y
```

Arguments

<code>cond</code>	A length-one logical vector that is not NA. Other types are coerced to logical if possible, ignoring any class. (Conditions of length greater than one are an error.)
<code>var</code>	A syntactical name for a variable.
<code>seq</code>	An expression evaluating to a vector (including a list and an expression) or to a pairlist or NULL. A factor value will be coerced to a character vector. This can be a long vector.
<code>expr, cons.expr, alt.expr, x, y</code>	An <i>expression</i> in a formal sense. This is either a simple expression or a so-called <i>compound expression</i> , usually of the form <code>{ expr1 ; expr2 }</code> .

Details

`break` breaks out of a `for`, `while` or `repeat` loop; control is transferred to the first statement outside the inner-most loop. `next` halts the processing of the current iteration and advances the looping index. Both `break` and `next` apply only to the innermost of nested loops.

Note that it is a common mistake to forget to put braces (`{ . . }`) around your statements, e.g., after `if(. .)` or `for(. . .)`. In particular, you should not have a newline between `}` and `else` to avoid a syntax error in entering a `if . . . else` construct at the keyboard or via `source`. For that reason, one (somewhat extreme) attitude of defensive programming is to always use braces, e.g., for `if` clauses.

The `seq` in a `for` loop is evaluated at the start of the loop; changing it subsequently does not affect the loop. If `seq` has length zero the body of the loop is skipped. Otherwise the variable `var` is assigned in turn the value of each element of `seq`. You can assign to `var` within the body of the loop, but this will not affect the next iteration. When the loop terminates, `var` remains as a variable containing its latest value. The `seq` is implicitly unclassed. For classed objects, one can use `as.list` to prepare a list to iterate over or `seq_along` to get an index vector and then explicitly extract individual elements (see also [lapply](#)).

The null coalescing operator `%||%` is a simple 1-line function: `x %||% y` is an idiomatic way to call

```
if (is.null(x)) y else x
# or equivalently, of course,
if(!is.null(x)) x else y
```

Inspired by Ruby, it was first proposed by Hadley Wickham.

Value

`if` returns the value of the expression evaluated, or `NULL` invisibly if none was (which may happen if there is no `else`).

`for`, `while` and `repeat` return `NULL` invisibly. `for` sets `var` to the last used element of `seq`, or to `NULL` if it was of length zero.

`break` and `next` do not return a value as they transfer control within the loop.

[Syntax](#) for the basic R syntax and operators, [Paren](#) for parentheses and braces.

[ifelse](#), [switch](#) for other ways to control flow.

Examples

```
for(i in 1:5) print(1:i)
for(n in c(2,5,10,20,50)) {
  x <- stats::rnorm(n)
  cat(n, ": ", sum(x^2), "\n", sep = "")
}
f <- factor(sample(letters[1:5], 10, replace = TRUE))
for(i in unique(f)) print(i)

res <- {}
res %||% "alternative result"
x <- head(x) %||% stop("parsed, but *not* evaluated..")

res <- if(sum(x) > 7.5) mean(x) # may be NULL
res %||% "sum(x) <= 7.5"
```

Description

R is released under the ‘GNU Public License’: see [license](#) for details. The license describes your right to use R. Copyright is concerned with ownership of intellectual rights, and some of the software used has conditions that the copyright must be explicitly stated: see the ‘Details’ section. We are grateful to these people and other contributors (see [contributors](#)) for the ability to use their work.

Details

The file ‘[R_HOME/COPYRIGHTS](#)’ lists the copyrights in full detail.

crossprod	<i>Matrix Cross-Product</i>
-----------	-----------------------------

Description

Given matrices `x` and `y` as arguments, return a matrix cross-product. This is formally equivalent to (but faster than) the call `t(x) %*% y (crossprod)` or `x %*% t(y) (tcrossprod)`.

These are generic functions since R 4.4.0: methods can be written individually or via the [matrixOps](#) group generic function; it dispatches to S3 and S4 methods.

Usage

```
crossprod(x, y = NULL, ...)
tcrossprod(x, y = NULL, ...)
```

Arguments

<code>x, y</code>	numeric or complex matrices (or vectors): <code>y = NULL</code> is taken to be the same matrix as <code>x</code> . Vectors are promoted to single-column or single-row matrices, depending on the context.
<code>...</code>	potential further arguments for methods.

Value

A double or complex matrix, with appropriate `dimnames` taken from `x` and `y`.

Note

When `x` or `y` are not matrices, they are treated as column or row matrices, but their `names` are usually **not** promoted to `dimnames`. Hence, currently, the last example has empty `dimnames`.

In the same situation, these matrix products (also `%*%`) are more flexible in promotion of vectors to row or column matrices, such that more cases are allowed, since R 3.2.0.

The propagation of NaN/Inf values, precision, and performance of matrix products can be controlled by `options("matprod")`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`%*%` and outer product `%O%`.

Examples

```

(z <- crossprod(1:4))      # = sum(1 + 2^2 + 3^2 + 4^2)
drop(z)                    # scalar
x <- 1:4; names(x) <- letters[1:4]; x
tcrossprod(as.matrix(x)) # is
identical(tcrossprod(as.matrix(x)),
           crossprod(t(x)))
tcrossprod(x)              # no dimnames

m <- matrix(1:6, 2, 3) ; v <- 1:3; v2 <- 2:1
stopifnot(identical(tcrossprod(v, m), v %*% t(m)),
           identical(tcrossprod(v, m), crossprod(v, t(m))),
           identical(crossprod(m, v2), t(m) %*% v2))

```

Cstack_info

*Report Information on C Stack Size and Usage***Description**

Report information on the C stack size and usage (if available).

Usage

```
Cstack_info()
```

Details

On most platforms, C stack information is recorded when R is initialized and used for stack-checking. If this information is unavailable, the `size` will be returned as NA, and stack-checking is not performed.

The information on the stack base address is thought to be accurate on Windows, Linux (using `glibc`), macOS and FreeBSD but a heuristic is used on other platforms. Because this might be slightly inaccurate, the current usage could be estimated as negative. (The heuristic is not used on embedded uses of R on platforms where the stack base information is not thought to be accurate.)

The ‘evaluation depth’ is the number of nested R expressions currently under evaluation: this has a limit controlled by `options("expressions")`.

Value

An integer vector. This has named elements

<code>size</code>	The size of the stack (in bytes), or NA if unknown.
<code>current</code>	The estimated current usage (in bytes), possibly NA.
<code>direction</code>	1 (stack grows down, the usual case) or -1 (stack grows up).
<code>eval_depth</code>	The current evaluation depth (including two calls for the call to <code>Cstack_info</code>).

Examples

```
Cstack_info()
```

cumsum

*Cumulative Sums, Products, and Extremes***Description**

Returns a vector whose elements are the cumulative sums, products, minima or maxima of the elements of the argument.

Usage

```
cumsum(x)
cumprod(x)
cummax(x)
cummin(x)
```

Arguments

`x` a numeric or complex (not `cummin` or `cummax`) object, or an object that can be coerced to one of these.

Details

These are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

Value

A vector of the same length and type as `x` (after coercion), except that `cumprod` returns a numeric vector for integer input (for consistency with `*`). Names are preserved.

An NA value in `x` causes the corresponding and following elements of the return value to be NA, as does integer overflow in `cumsum` (with a warning). In the complex case with NAs, these NA elements may have finite real or imaginary parts, notably for `cumsum()`, fulfilling the identity $\text{Im}(\text{cumsum}(x)) \equiv \text{cumsum}(\text{Im}(x))$.

S4 methods

`cumsum` and `cumprod` are S4 generic functions: methods can be defined for them individually or via the [Math](#) group generic. `cummax` and `cummin` are individually S4 generic functions.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X. (`cumsum` only.)

Examples

```
cumsum(1:10)
cumprod(1:10)
cummin(c(3:1, 2:0, 4:2))
cummax(c(3:1, 2:0, 4:2))
```

curlGetHeaders	<i>Retrieve Headers from URLs</i>
----------------	-----------------------------------

Description

Retrieve the headers for a URL for a supported protocol such as 'http://', 'ftp://', 'https://' and 'ftps://'.

Usage

```
curlGetHeaders(url, redirect = TRUE, verify = TRUE,
               timeout = 0L, TLS = "")
```

Arguments

url	character string specifying the URL.
redirect	logical: should redirections be followed?
verify	logical: should certificates be verified as valid and applying to that host?
timeout	integer: the maximum time in seconds the request is allowed to take. Non-positive and invalid values are ignored (including the default). (Added in R 4.1.0.)
TLS	character: the minimum version of the TLS protocol to be used for 'https://' URLs: the default ("") is no restriction beyond that of the underlying libcurl (usually 1.0). Other valid values are "1.1", "1.2" (both for libcurl 7.34.0 and later) and "1.3" (7.52.0 and later), if supported by the underlying version of libcurl and the SSL library it uses.

Details

This reports what `curl -I -L` or `curl -I` would report. For a 'ftp://' URL the 'headers' are a record of the conversation between client and server before data transfer.

Only 500 header lines will be reported: there is a limit of 20 redirections so this should suffice (and even 20 would indicate problems).

If argument `timeout` is not set to a positive integer this uses `getOption("timeout")` which defaults to 60 seconds. As the request cannot be interrupted you may want to consider a shorter value.

To see all the details of the interaction with the server(s) set `options(internet.info = 1)`.

HTTP[S] servers are allowed to refuse requests to read the headers and some do: this will result in a status of 405.

For possible issues with secure URLs (especially on Windows) see [download.file](#).

There is a security risk in not verifying certificates, but as only the headers are captured it is slight. Usually looking at the URL in a browser will reveal what the problem is (and it may well be machine-specific).

Value

A character vector with integer attribute "status" (the last-received 'status' code). If redirection occurs this will include the headers for all the URLs visited.

For the interpretation of 'status' codes see https://en.wikipedia.org/wiki/List_of_HTTP_status_codes and https://en.wikipedia.org/wiki/List_of_FTP_server_return_codes. A successful FTP connection will usually have status 250, 257 or 350.

See Also

`capabilities("libcurl")` to see if this is supported. `libcurlVersion` for the version of libcurl in use.

`options` HTTPUserAgent and timeout are used.

Examples

```
## needs Internet access, results vary
curlGetHeaders("http://bugs.r-project.org") ## this redirects to https://
## 2023-04: replaces slow and unreliable https://httpbin.org/status/404
curlGetHeaders("https://developer.R-project.org/inet-tests/not-found")
## returns status
```

cut

*Convert Numeric to Factor***Description**

`cut` divides the range of `x` into intervals and codes the values in `x` according to which interval they fall. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

Usage

```
cut(x, ...)

## Default S3 method:
cut(x, breaks, labels = NULL,
    include.lowest = FALSE, right = TRUE, dig.lab = 3,
    ordered_result = FALSE, ...)
```

Arguments

<code>x</code>	a numeric vector which is to be converted to a factor by cutting.
<code>breaks</code>	either a numeric vector of two or more unique cut points or a single number (greater than or equal to 2) giving the number of intervals into which <code>x</code> is to be cut.
<code>labels</code>	labels for the levels of the resulting category. By default, labels are constructed using " <code>(a,b]</code> " interval notation. If <code>labels = FALSE</code> , simple integer codes are returned instead of a factor.
<code>include.lowest</code>	logical, indicating if an ' <code>x[i]</code> ' equal to the lowest (or highest, for <code>right = FALSE</code>) ' <code>breaks</code> ' value should be included.

<code>right</code>	logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
<code>dig.lab</code>	integer which is used when labels are not given. It determines the number of digits used in formatting the break numbers.
<code>ordered_result</code>	logical: should the result be an ordered factor?
<code>...</code>	further arguments passed to or from other methods.

Details

When `breaks` is specified as a single number, the range of the data is divided into `breaks` pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If `x` is a constant vector, equal-length intervals are created, one of which includes the single value.)

If a `labels` parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed as "`(b1, b2]`", "`(b2, b3]`" etc. for `right = TRUE` and as "`[b1, b2)`", ... if `right = FALSE`. In this case, `dig.lab` indicates the minimum number of digits should be used in formatting the numbers `b1, b2, ...`. A larger value (up to 12) will be used if needed to distinguish between any pair of endpoints: if this fails labels such as "Range3" will be used. Formatting is done by `formatC`.

The default method will sort a numeric vector of `breaks`, but other methods are not required to and `labels` will correspond to the intervals after sorting.

As from R 3.2.0, `getOption("OutDec")` is consulted when labels are constructed for `labels = NULL`.

Value

A `factor` is returned, unless `labels = FALSE` which results in an integer vector of level codes.

Values which fall outside the range of `breaks` are coded as NA, as are NaN and NA values.

Note

Instead of `table(cut(x, br))`, `hist(x, br, plot = FALSE)` is more efficient and less memory hungry. Instead of `cut(*, labels = FALSE)`, `findInterval()` is more efficient.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`split` for splitting a variable according to a group factor; `factor`, `tabulate`, `table`, `findInterval`.

`quantile` for ways of choosing breaks of roughly equal content (rather than length).

`.bincode` for a bare-bones version.

Examples

```

Z <- stats::rnorm(10000)
table(cut(Z, breaks = -6:6))
sum(table(cut(Z, breaks = -6:6, labels = FALSE)))
sum(graphics::hist(Z, breaks = -6:6, plot = FALSE)$counts)

cut(rep(1,5), 4) #-- dummy
tx0 <- c(9, 4, 6, 5, 3, 10, 5, 3, 5)
x <- rep(0:8, tx0)
stopifnot(table(x) == tx0)

table( cut(x, breaks = 8))
table( cut(x, breaks = 3*(-2:5)))
table( cut(x, breaks = 3*(-2:5), right = FALSE))

##--- some values OUTSIDE the breaks :
table(cx <- cut(x, breaks = 2*(0:4)))
table(cx1 <- cut(x, breaks = 2*(0:4), right = FALSE))
which(is.na(cx)); x[is.na(cx)] #-- the first 9 values 0
which(is.na(cx1)); x[is.na(cx1)] #-- the last 5 values 8

## Label construction:
y <- stats::rnorm(100)
table(cut(y, breaks = pi/3*(-3:3)))
table(cut(y, breaks = pi/3*(-3:3), dig.lab = 4))

table(cut(y, breaks = 1*(-3:3), dig.lab = 4))
# extra digits don't "harm" here
table(cut(y, breaks = 1*(-3:3), right = FALSE))
#- the same, since no exact INT!

## sometimes the default dig.lab is not enough to be avoid confusion:
aaa <- c(1,2,3,4,5,2,3,4,5,6,7)
cut(aaa, 3)
cut(aaa, 3, dig.lab = 4, ordered_result = TRUE)

## one way to extract the breakpoints
labs <- levels(cut(aaa, 3))
cbind(lower = as.numeric( sub("\\((.+),.*", "\\1", labs) ),
      upper = as.numeric( sub("[^,]*,([^\"]*)\\", "\\1", labs) ))

```

cut.POSIXt

Convert a Date or Date-Time Object to a Factor

Description

Method for `cut` applied to date-time objects.

Usage

```

## S3 method for class 'POSIXt'
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
    right = FALSE, ...)

```

```
## S3 method for class 'Date'
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
    right = FALSE, ...)
```

Arguments

<code>x</code>	an object inheriting from class "POSIXt" or "Date".
<code>breaks</code>	a vector of cut points <i>or</i> number giving the number of intervals which <code>x</code> is to be cut into <i>or</i> an interval specification, one of "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year", optionally preceded by an integer and a space, or followed by "s". (For "Date" objects only interval specifications using "day", "week", "month", "quarter" and "year" are allowed.)
<code>labels</code>	labels for the levels of the resulting category. By default, labels are constructed from the left-hand end of the intervals (which are included for the default value of <code>right</code>). If <code>labels = FALSE</code> , simple integer codes are returned instead of a factor.
<code>start.on.monday</code>	logical. If <code>breaks = "weeks"</code> , should the week start on Mondays or Sundays?
<code>right, ...</code>	arguments to be passed to or from other methods.

Details

Note that the default for `right` differs from the [default method](#). Using `include.lowest = TRUE` will include both ends of the range of dates.

Using `breaks = "quarter"` will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1 (based upon `min(x)`) as appropriate.

A vector of `breaks` will be sorted before use: `labels` should correspond to the sorted vector.

Value

A factor is returned, unless `labels = FALSE` which returns the integer level codes.

Values which fall outside the range of `breaks` are coded as NA, as are and NA values.

See Also

[seq.POSIXt](#), [seq.Date](#), [cut](#)

Examples

```
## random dates in a 10-week period
cut(ISOdate(2001, 1, 1) + 70*86400*stats::runif(100), "weeks")
cut(as.Date("2001/1/1") + 70*stats::runif(100), "weeks")

# The standards all have midnight as the start of the day, but some
# people incorrectly interpret it at the end of the previous day ...
tm <- seq(as.POSIXct("2012-06-01 06:00"), by = "6 hours", length.out = 24)
aggregate(1:24, list(day = cut(tm, "days")), mean)
# and a version with midnight included in the previous day:
aggregate(1:24, list(day = cut(tm, "days", right = TRUE)), mean)
```

data.class	<i>Object Classes</i>
------------	-----------------------

Description

Determine the class of an arbitrary R object.

Usage

```
data.class(x)
```

Arguments

`x` an R object.

Value

character string giving the *class* of `x`.

The class is the (first element) of the `class` attribute if this is non-NULL, or inferred from the object's `dim` attribute if this is non-NULL, or `mode(x)`.

Simply speaking, `data.class(x)` returns what is typically useful for method dispatching. (Or, what the basic creator functions already and maybe eventually all will attach as a class attribute.)

Note

For compatibility reasons, there is one exception to the rule above: When `x` is *integer*, the result of `data.class(x)` is "numeric" even when `x` is classed.

See Also

[class](#)

Examples

```
x <- LETTERS
data.class(factor(x))           # has a class attribute
data.class(matrix(x, ncol = 13)) # has a dim attribute
data.class(list(x))            # the same as mode(x)
data.class(x)                  # the same as mode(x)

stopifnot(data.class(1:2) == "numeric") # compatibility "rule"
```

data.frame

*Data Frames***Description**

The function `data.frame()` creates data frames, tightly coupled collections of variables which share many of the properties of matrices and of lists, used as the fundamental data structure by most of R's modeling software.

Usage

```
data.frame(..., row.names = NULL, check.rows = FALSE,
           check.names = TRUE, fix.empty.names = TRUE,
           stringsAsFactors = FALSE)
```

Arguments

<code>...</code>	these arguments are of either the form <code>value</code> or <code>tag = value</code> . Component names are created based on the tag (if present) or the deparsed argument itself.
<code>row.names</code>	NULL or a single integer or character string specifying a column to be used as row names, or a character or integer vector giving the row names for the data frame.
<code>check.rows</code>	if TRUE then the rows are checked for consistency of length and names.
<code>check.names</code>	logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names and are not duplicated. If necessary they are adjusted (by make.names) so that they are.
<code>fix.empty.names</code>	logical indicating if arguments which are “unnamed” (in the sense of not being formally called as <code>someName = arg</code>) get an automatically constructed name or rather name “”. Needs to be set to FALSE even when <code>check.names</code> is false if “” names should be kept.
<code>stringsAsFactors</code>	logical: should character vectors be converted to factors? The ‘factory-fresh’ default has been TRUE previously but has been changed to FALSE for R 4.0.0.

Details

A data frame is a list of variables of the same number of rows with unique row names, given class `"data.frame"`. If no variables are included, the row names determine the number of rows.

The column names should be non-empty, and attempts to use empty names will have unsupported results. Duplicate column names are allowed, but you need to use `check.names = FALSE` for `data.frame` to generate such a data frame. However, not all operations on data frames will preserve duplicated column names: for example matrix-like subsetting will force column names in the result to be unique.

`data.frame` converts each of its arguments to a data frame by calling [as.data.frame](#) (`optional = TRUE`). As that is a generic function, methods can be written to change the behaviour of arguments according to their classes: R comes with many such methods. Character variables passed to `data.frame` are converted to factor columns if not protected by [I](#) and argument `stringsAsFactors` is true. If a list or data frame or matrix

is passed to `data.frame` it is as if each component or column had been passed as a separate argument (except for matrices protected by `I`).

Objects passed to `data.frame` should have the same number of rows, but atomic vectors (see `is.vector`), factors and character vectors protected by `I` will be recycled a whole number of times if necessary (including as elements of list arguments).

If row names are not supplied in the call to `data.frame`, the row names are taken from the first component that has suitable names, for example a named vector or a matrix with rownames or a data frame. (If that component is subsequently recycled, the names are discarded with a warning.) If `row.names` was supplied as `NULL` or no suitable component was found the row names are the integer sequence starting at one (and such row names are considered to be ‘automatic’, and not preserved by `as.matrix`).

If row names are supplied of length one and the data frame has a single row, the `row.names` is taken to specify the row names and not a column (by name or number).

Names are removed from vector inputs not protected by `I`.

Value

A data frame, a matrix-like structure whose columns may be of differing types (numeric, logical, factor and character and so on).

How the names of the data frame are created is complex, and the rest of this paragraph is only the basic story. If the arguments are all named and simple objects (not lists, matrices of data frames) then the argument names give the column names. For an unnamed simple argument, a deparsed version of the argument is used as the name (with an enclosing `I(...)` removed). For a named matrix/list/data frame argument with more than one named column, the names of the columns are the name of the argument followed by a dot and the column name inside the argument: if the argument is unnamed, the argument’s column names are used. For a named or unnamed matrix/list/data frame argument that contains a single column, the column name in the result is the column name in the argument. Finally, the names are adjusted to be unique and syntactically valid unless `check.names = FALSE`.

Note

In versions of R prior to 2.4.0 `row.names` had to be character: to ensure compatibility with such versions of R, supply a character vector as the `row.names` argument.

L3 <- LETTERS[1:3]
char <- sample(L3, 10, replace = TRUE)
(d <- data.frame(x = 1, y = 1:10, char = char))
```

```
## The "same" with automatic column names:
data.frame(1, 1:10, sample(L3, 10, replace = TRUE))

is.data.frame(d)

## enable automatic conversion of character arguments to factor columns:
(dd <- data.frame(d, fac = letters[1:10], stringsAsFactors = TRUE))
rbind(class = sapply(dd, class), mode = sapply(dd, mode))

stopifnot(1:10 == row.names(d)) # {coercion}

(d0 <- d[, FALSE]) # data frame with 0 columns and 10 rows
(d.0 <- d[FALSE, ]) # <0 rows> data frame (3 named cols)
(d00 <- d0[FALSE, ]) # data frame with 0 columns and 0 rows
```

data.matrix

Convert a Data Frame to a Numeric Matrix

Description

Return the matrix obtained by converting all the variables in a data frame to numeric mode and then binding them together as the columns of a matrix. Factors and ordered factors are replaced by their internal codes.

Usage

```
data.matrix(frame, rownames.force = NA)
```

Arguments

frame	a data frame whose components are logical vectors, factors or numeric or character vectors.
rownames.force	logical indicating if the resulting matrix should have character (rather than NULL) rownames . The default, NA, uses NULL rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.

Details

Logical and factor columns are converted to integers. Character columns are first converted to factors and then to integers. Any other column which is not numeric (according to [is.numeric](#)) is converted by [as.numeric](#) or, for S4 objects, [as](#)(, "numeric"). If all columns are integer (after conversion) the result is an integer matrix, otherwise a numeric (double) matrix.

Value

If frame inherits from class "data.frame", an integer or numeric matrix of the same dimensions as frame, with dimnames taken from the row.names (or NULL, depending on rownames.force) and names.

Otherwise, the result of [as.matrix](#).

Note

The default behaviour for data frames differs from R < 2.5.0 which always gave the result character rownames.

[as.matrix](#), [data.frame](#), [matrix](#).

Examples

```
DF <- data.frame(a = 1:3, b = letters[10:12],
                 c = seq(as.Date("2004-01-01"), by = "week", length.out = 3),
                 stringsAsFactors = TRUE)
data.matrix(DF[1:2])
data.matrix(DF)
```

date

System Date and Time

Description

Returns a character string of the current system date and time.

Usage

```
date()
```

Value

The string has the form "Fri Aug 20 11:11:00 1999", i.e., length 24, since it relies on POSIX's `ctime` ensuring the above fixed format. Timezone and Daylight Saving Time are taken account of, but *not* indicated in the result.

The day and month abbreviations are always in English, irrespective of locale.

[Sys.Date](#) and [Sys.time](#); [Date](#) and [DateTimeClasses](#) for objects representing date and time.

Examples

```
(d <- date())
nchar(d) == 24

## something similar in the current locale
## depending on ctime; e.g. %e could be %d:
format(Sys.time(), "%a %b %e %H:%M:%S %Y")
```

Dates	<i>Date Class</i>
-------	-------------------

Description

Description of the class "Date" representing calendar dates.

Usage

```
## S3 method for class 'Date'
summary(object, digits = 12, ...)

## S3 method for class 'Date'
print(x, max = NULL, ...)
```

Arguments

object, x	a Date object to be summarized or printed.
digits	number of significant digits for the computations.
max	numeric or NULL, specifying the maximal number of entries to be printed. By default, when NULL, <code>getOption("max.print")</code> used.
...	further arguments to be passed from or to other methods.

Details

Dates are represented as the number of days since 1970-01-01, with negative values for earlier dates. They are always printed following the rules of the current Gregorian calendar, even though that calendar was not in use long ago (it was adopted in 1752 in Great Britain and its colonies). When printing there is assumed to be a year zero.

It is intended that the date should be an integer value, but this is not enforced in the internal representation. Fractional days will be ignored when printing. It is possible to produce fractional days via the `mean` method or by adding or subtracting (see [Ops.Date](#)).

When a date is converted to a date-time (for example by `as.POSIXct` or `as.POSIXlt`) its time is taken as midnight in UTC.

Printing dates involves conversion to class "`POSIXlt`" which treats dates of more than about 780 billion days (2.1 billion years) from present as NA.

For the many methods see `methods(class = "Date")`. Several are documented separately, see below.

Warning

Do not use `identical()` on objects of class "Date". Their `storage.mode` may be "double" or "integer", and which is chosen has depended on the version of R used to create the object.

See Also

`Sys.Date` for the current date.

`weekdays` for convenience extraction functions.

Methods with extra arguments and documentation:

`Ops.Date` for operators on "Date" objects.

`format.Date` for conversion to and from character strings.

`axis.Date` and `hist.Date` for plotting.

`seq.Date`, `cut.Date`, and `round.Date` for utility operations.

`DateTimeClasses` for date-time classes.

Examples

```
(today <- Sys.Date())
format(today, "%d %b %Y") # with month as a word
(tenweeks <- seq(today, length.out=10, by="1 week")) # next ten weeks
weekdays(today)
months(tenweeks)

(Dls <- as.Date(.leap.seconds))

## Show use of year zero:
(z <- as.Date("01-01-01")) # how it is printed depends on the OS
z - 365 # so year zero was a leap year.
as.Date("00-02-29")
# if you want a different format, consider something like (if supported)
## Not run: format(z, "%04Y-%m-%d") # "0001-01-01"
format(z, "%_4Y-%m-%d") # " 1-01-01"
format(z, "%_Y-%m-%d") # "1-01-01"

## End(Not run)

## length(<Date>) <- n now works
ls <- Dls; length(ls) <- 12
l2 <- Dls; length(l2) <- 5 + length(Dls)
stopifnot(exprs = {
  ## length(.) <- * is compatible to subsetting/indexing:
  identical(ls, Dls[seq_along(ls)])
  identical(l2, Dls[seq_along(l2)])
  ## has filled with NAs
  is.na(l2[(length(Dls)+1):length(l2)])
})
```

Description

Description of the classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```
## S3 method for class 'POSIXct'
print(x, tz = "", usetz = TRUE, max = NULL,
      digits = getOption("digits.secs"), ...)

## S3 method for class 'POSIXct'
summary(object, digits = 15, ...)

time + z
z + time
time - z
time1 lop time2

.leap.seconds
```

Arguments

x, object	an object to be printed or summarized from one of the date-time classes.
tz, usetz	for timezone formatting, passed to <code>format.POSIXct</code> .
max	numeric or NULL, specifying the maximal number of entries to be printed. By default, when NULL, <code>getOption("max.print")</code> used.
digits	number of digits to format fractional seconds in the case of <code>print()</code> ; number of <i>significant</i> digits for the computations: should be high enough to represent the least important time unit exactly.
...	further arguments to be passed from or to other methods.
time	date-time objects.
time1, time2	date-time objects or character vectors. (Character vectors are converted by <code>as.POSIXct</code> .)
z	a numeric vector (in seconds).
lop	one of ==, !=, <, <=, > or >=.

Details

There are two basic classes of date/times. Class "POSIXct" represents the (signed) number of seconds since the beginning of 1970 (in the UTC time zone) as a numeric vector. Class "POSIXlt" is internally a `list` of vectors with components named `sec`, `min`, `hour` for the time, `mday`, `mon`, and `year`, for the date, `wday`, `yday` for the day of the week and day of the year, `isdst`, a Daylight Saving Time flag, and sometimes (both *optional*) `zone`, a string for the time zone, and `gmtoff`, offset in seconds from GMT, see the section 'Details on POSIXlt' below for more details.

The classes correspond to the POSIX/C99 constructs of ‘calendar time’ (the `time_t` data type, “ct”), and ‘local time’ (or broken-down time, the ‘`struct tm`’ data type, “lt”), from which they also inherit their names.

"POSIXct" is more convenient for including in data frames, and "POSIXlt" is closer to human-readable forms. A virtual class "POSIXt" exists from which both of the classes inherit: it is used to allow operations such as subtraction to mix the two classes.

Logical comparisons and some arithmetic operations are available for both classes. One can add or subtract a number of seconds from a date-time object, but not add two date-time objects. Subtraction of two date-time objects is equivalent to using `difftime`. Be aware that "POSIXlt" objects will be interpreted as being in the current time zone for these operations unless a time zone has been specified.

Note that these arithmetic, comparison and logical operations *currently* work via coercion to "POSIXct" which may lose accuracy of (typically fractional) seconds. Hence, e.g., `t1 == t2` may be true where the datetime objects differ slightly and (at least) one of them is POSIXlt.

Further implemented methods comprise `mean`, `summary`, `unique`, `is.finite`, `length<-`, `pretty`,...; also **graphics** package’s `hist` and `Axis`; use `methods(class = "POSIXt")`, `.. class = "POSIXlt"` and "POSIXct" to see more.

Both classes may have an attribute "tzone", specifying the time zone. Note however that their meaning differ, see the section ‘Time Zones’ below for more details.

Unfortunately, the conversion is complicated by the operation of time zones and leap seconds (according to this version of R’s data, 27 days have been 86401 seconds long so far, the last being on (actually, immediately before) 2017-01-01: the times of the extra seconds are in the object `.leap.seconds`). The details of this are entrusted to the OS services where possible. It seems that some rare systems used to use leap seconds, but all known current platforms ignore them (as required by POSIX). This is detected and corrected for at build time, so "POSIXct" times used by R do not include leap seconds on any platform.

Using `c` on "POSIXlt" objects converts them to the current time zone, and on "POSIXct" objects drops "tzone" attributes if they are not all the same.

A few times have specific issues. First, the leap seconds are ignored, and real times such as "2005-12-31 23:59:60" are (probably) treated as the next second. However, they will never be generated by R, and are unlikely to arise as input. Second, on some OSes there is a problem in the POSIX/C99 standard with "1969-12-31 23:59:59 UTC", which is -1 in calendar time and that value is on those OSes also used as an error code. Thus `as.POSIXct("1969-12-31 23:59:59", format = "%Y-%m-%d %H:%M:%S", tz = "UTC")` may give NA, and hence `as.POSIXct("1969-12-31 23:59:59", tz = "UTC")` will give "1969-12-31 23:59:00". Other OSes (including the code used by R on Windows) report errors separately and so are able to handle that time as valid.

The print methods respect `options("max.print")`.

Time zones

"POSIXlt" objects will often have an attribute "tzone", a character vector of length 3 giving the time zone name (from the TZ environment variable or argument `tz` of functions creating "POSIXlt" objects; "" marks the current time zone) and the names of the base time zone and the alternate (daylight-saving) time zone. Sometimes this may just be of length one, giving the [time zone](#) name.

"POSIXct" objects may also have an attribute "tzone", a character vector of length one. If set to a non-empty value, it will determine how the object is converted to class "POSIXlt" and in particular how it is printed. This is usually desirable, but if you want to specify an object in

a particular time zone but to be printed in the current time zone you may want to remove the "tzone" attribute.

Details on POSIXlt

Class "POSIXlt" is internally a named `list` of vectors representing date-times, with the following list components

`sec` 0–61: seconds, allowing for leap seconds.

`min` 0–59: minutes.

`hour` 0–23: hours.

`mday` 1–31: day of the month.

`mon` 0–11: months after the first of the year.

`year` years since 1900.

`wday` 0–6 day of the week, starting on Sunday.

`yday` 0–365: day of the year (365 only in leap years).

`isdst` Daylight Saving Time flag. Positive if in force, zero if not, negative if unknown.

`zone` (Optional.) The abbreviation for the time zone in force at that time: "" if unknown (but "" might also be used for UTC).

`gmtoff` (Optional.) The offset in seconds from GMT: positive values are East of the meridian. Usually NA if unknown, but 0 could mean unknown.

The components must be in this order: that was only minimally checked prior to R 4.3.0. All objects created in R 4.3.0 have the optional components. From earlier versions of R, the last two components will not be present for times in UTC and are platform-dependent. Currently `gmtoff` is set on almost all current platforms: those based on BSD or `glibc` (including Linux and macOS) and those using the `tzcode` implementation shipped with R (including Windows and by default macOS).

Note that the internal list structure is somewhat hidden, as many methods (including `length()`, `print()` and `str()`) apply to the abstract date-time vector, as for "POSIXct". One can extract and replace *single* components via `[]` indexing with *two* indices (see the examples). The `as.matrix()` method gets the components as `numeric` columns without the zone, whereas `data.frame()` and the `as.data.frame` method convert a "POSIXlt" to a "POSIXct" one column data frame, to treat datetime objects analogously to atomic vectors.

The components of "POSIXlt" are `integer` vectors, except `sec` (`double`) and `zone` (`character`). However most users will coerce numeric values for the first to real and the rest back to integer.

Components `wday` and `yday` are for information, and are not used in the conversion to calendar time nor for printing, `format()`, or in `as.character()`.

However, component `isdst` is needed to distinguish times at the end of DST: typically 1am to 2am occurs twice, first in DST and then in standard time. At all other times `isdst` can be deduced from the first six values, but the behaviour if it is set incorrectly is platform-dependent. For example Linux/glibc when checked fixed up incorrect values in time zones which support DST but gave an error on value 1 in those without DST.

For “ragged” and out-of-range vs “balanced” "POSIXlt" objects, see `balancePOSIXlt()`.

Sub-second Accuracy

Classes "POSIXct" and "POSIXlt" are able to express fractions of a second where the latter allows for higher accuracy. Consequently, conversion of fractions between the two forms may not be exact, but will have better than microsecond accuracy.

Fractional seconds are printed only if `options("digits.secs")` is set: see `strftime`.

Valid ranges for times

The "POSIXlt" class can represent a very wide range of times (up to billions of years), but such times can only be interpreted with reference to a time zone.

The concept of time zones was first adopted in the nineteenth century, and the Gregorian calendar was introduced in 1582 but not universally adopted until 1927. OS services almost invariably assume the Gregorian calendar and may assume that the time zone that was first enacted for the location was in force before that date. (The earliest legislated time zone seems to have been London on 1847-12-01.) Some OSes assume the previous use of 'local time' based on the longitude of a location within the time zone.

Most operating systems represent POSIXct times as C type `long`. This means that on 32-bit OSes this covers the period 1902 to 2037. On all known 64-bit platforms and for the code we use on 32-bit Windows, the range of representable times is billions of years: however, not all can convert correctly times before 1902 or after 2037. A few benighted OSes used a unsigned type and so cannot represent times before 1970.

Where possible the platform limits are detected, and outside the limits we use our own C code. This uses the offset from GMT in use either for 1902 (when there was no DST) or that predicted for one of 2030 to 2037 (chosen so that the likely DST transition days are Sundays), and uses the alternate (daylight-saving) time zone only if `isdst` is positive or (if `-1`) if DST was predicted to be in operation in the 2030s on that day.

Note that there are places (e.g., Rome) whose offset from UTC varied in the years prior to 1902, and these will be handled correctly only where there is OS support.

There is no reason to assume that the DST rules will remain the same in the future: the US legislated in 2005 to change its rules as from 2007, with a possible future reversion. So conversions for times more than a year or two ahead are speculative. Other countries have changed their rules (and indeed, if DST is used at all) at a few days' notice. So representations and conversion of future dates are tentative. This also applies to dates after the in-use version of the time-zone database – not all platforms keep it up to date, which includes that shipped with older versions of R where used (which it is by default on Windows and macOS).

Warnings

Some Unix-like systems (especially Linux ones) do not have environment variable `TZ` set, yet have internal code that expects it (as does POSIX). We have tried to work around this, but if you get unexpected results try setting `TZ`. See `Sys.timezone` for valid settings.

Great care is needed when comparing objects of class "POSIXlt". Not only are components and attributes optional; several components may have values meaning 'not yet determined' and the same time represented in different time zones will look quite different.

The *order* of the list components of "POSIXlt" objects must not be changed, as several C-based conversion methods rely on the order for efficiency.

Do not use `identical()` on objects of class "POSIXct", rather `==` or `all.equal`. Their `storage.mode` may be "double" or "integer" and you should not rely on which is chosen.

`strptime` for conversion to and from character representations.

`Sys.time` for clock time as a "POSIXct" object.

`difftime` for time intervals.

`balancePOSIXlt()` for balancing or filling "ragged" POSIXlt objects.

`cut.POSIXt`, `seq.POSIXt`, `round.POSIXt` and `trunc.POSIXt` for methods for these classes.

`weekdays`, for convenience extraction functions (also including `months()`, `quarters()`, `julian()`).

Examples

```
(z <- Sys.time())           # the current date, as class "POSIXct"

Sys.time() - 3600           # an hour ago

as.POSIXlt(Sys.time(), "GMT") # the current time in GMT
format(.leap.seconds)        # the leap seconds in your time zone
print(.leap.seconds, tz = "America/Los_Angeles") # and in Seattle's

## look at *internal* representation of "POSIXlt" :
leapS <- as.POSIXlt(.leap.seconds)
names(unclass(leapS)) ; is.list(leapS)
## str() on inner structure needs unclass():
utils::str(unclass(leapS), vec.len = 7)
## show all components
data.frame(unclass(leapS))
## Omitting "tzzone" attrib, numeric matrix w/ 10 columns (27 x 10, currently) :
(leapm <- as.matrix(leapS))
stopifnot(identical(ncol(leapm), 10L), is.numeric(leapm)) # was character in R <= 4.6.0

## Extracting *single* components of POSIXlt objects:
leapS[1 : 5, "year"]
leapS[17:22, "mon" ]
```

Description

Reads or writes an R object from/to a file in Debian Control File format.

Usage

```
read.dcf(file, fields = NULL, all = FALSE, keep.white = NULL)

write.dcf(x, file = "", append = FALSE, useBytes = FALSE,
          indent = 0.1 * getOption("width"),
          width = 0.9 * getOption("width"),
          keep.white = NULL)
```

Arguments

<code>file</code>	either a character string naming a file or a connection . "" indicates output to the console. For <code>read.dcf</code> this can name a compressed file (see gzfile).
<code>fields</code>	a character vector with the names of the fields to read from the DCF file. Default is to read all fields.
<code>all</code>	a logical indicating whether in case of multiple occurrences of a field in a record, all these should be gathered. If <code>all</code> is false (default), only the last such occurrence is used.
<code>keep.white</code>	a character vector with the names of the fields for which whitespace should be kept as is, or <code>NULL</code> (default) indicating that there are no such fields. Coerced to character if possible. For fields where whitespace is not to be kept as is, <code>read.dcf</code> removes leading and trailing whitespace, and <code>write.dcf</code> folds using strwrap .
<code>x</code>	the object to be written, typically a data frame. If not, it is attempted to coerce <code>x</code> to a data frame.
<code>append</code>	logical. If <code>TRUE</code> , the output is appended to the file. If <code>FALSE</code> , any existing file of the name is destroyed.
<code>useBytes</code>	logical to be passed to writeLines() , see there: “for expert use”.
<code>indent</code>	a positive integer specifying the indentation for continuation lines in output entries.
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.

Details

DCF is a simple format for storing databases in plain text files that can easily be directly read and written by humans. DCF is used in various places to store R system information, like descriptions and contents of packages.

The DCF rules as implemented in R are:

1. A database consists of one or more records, each with one or more named fields. Not every record must contain each field. Fields may appear more than once in a record.
2. Regular lines start with a non-whitespace character.
3. Regular lines are of form `tag:value`, i.e., have a name `tag` and a value for the field, separated by `:` (only the first `:` counts). The value can be empty (i.e., whitespace only).
4. Lines starting with whitespace are continuation lines (to the preceding field) if at least one character in the line is non-whitespace. Continuation lines where the only non-whitespace character is a `'.'` are taken as blank lines (allowing for multi-paragraph field values).
5. Records are separated by one or more empty (i.e., whitespace only) lines.
6. Individual lines may not be arbitrarily long; prior to R 3.0.2 the length limit was approximately 8191 bytes per line.

Note that `read.dcf(all = FALSE)` reads the file byte-by-byte. This allows a 'DESCRIPTION' file to be read and only its ASCII fields used, or its 'Encoding' field used to re-encode the remaining fields.

`write.dcf` does not write NA fields.

Value

The default `read.dcf(all = FALSE)` returns a character matrix with one row per record and one column per field. Leading and trailing whitespace of field values is ignored unless a field is listed in `keep.white`. If a tag name is specified in the file, but the corresponding value is empty, then an empty string is returned. If the tag name of a field is specified in `fields` but never used in a record, then the corresponding value is NA. If fields are repeated within a record, the last one encountered is returned. Malformed lines lead to an error.

For `read.dcf(all = TRUE)` a data frame is returned, again with one row per record and one column per field. The columns are lists of character vectors for fields with multiple occurrences, and character vectors otherwise.

Note that an empty file is a valid DCF file, and `read.dcf` will return a zero-row matrix or data frame.

For `write.dcf`, invisible NULL.

Note

As from R 3.4.0, 'whitespace' in all cases includes newlines.

References

<https://www.debian.org/doc/debian-policy/ch-controlfields.html>.

Note that R does not require encoding in UTF-8, which is a recent Debian requirement.

[write.table](#).

[available.packages](#), which uses `read.dcf` to read the indices of package repositories.

Examples

```
## Create a reduced version of the DESCRIPTION file in package 'splines'
x <- read.dcf(file = system.file("DESCRIPTION", package = "splines"),
              fields = c("Package", "Version", "Title"))
write.dcf(x)

## An online DCF file with multiple records
con <- url("https://cran.r-project.org/src/contrib/PACKAGES")
y <- read.dcf(con, all = TRUE)
close(con)
utils::str(y)
```

debug

*Debug a Function***Description**

Set, unset or query the debugging flag on a function. The `text` and `condition` arguments are the same as those that can be supplied via a call to `browser`. They can be retrieved by the user once the browser has been entered, and provide a mechanism to allow users to identify which breakpoint has been activated.

Usage

```
debug(fun, text = "", condition = NULL, signature = NULL)
debugonce(fun, text = "", condition = NULL, signature = NULL)
undebug(fun, signature = NULL)
isdebugged(fun, signature = NULL)
debuggingState(on = NULL)
```

Arguments

<code>fun</code>	any interpreted R function or a character string naming one.
<code>text</code>	a text string that can be retrieved when the browser is entered.
<code>condition</code>	a condition that can be retrieved when the browser is entered.
<code>signature</code>	an optional method signature. If specified, the method is debugged, rather than its generic.
<code>on</code>	logical; a call to the support function <code>debuggingState</code> returns <code>TRUE</code> if debugging is globally turned on, <code>FALSE</code> otherwise. An argument of one or the other of those values sets the state. If the debugging state is <code>FALSE</code> , none of the debugging actions will occur (but explicit <code>browser</code> calls in functions will continue to work).

Details

When a function flagged for debugging is entered, normal execution is suspended and the body of function is executed one statement at a time. A new `browser` context is initiated for each step (and the previous one destroyed).

At the debug prompt the user can enter commands or R expressions, followed by a newline. The commands are described in the `browser` help topic.

To debug a function which is defined inside another function, single-step through to the end of its definition, and then call `debug` on its name.

If you want to debug a function not starting at the very beginning, use `trace(..., at = *)` or `setBreakpoint`.

Using `debug` is persistent, and unless debugging is turned off the debugger will be entered on every invocation (note that if the function is removed and replaced the debug state is not preserved). Use `debugonce()` to enter the debugger only the next time the function is invoked.

To debug an S4 method by explicit signature, use `signature`. When specified, `signature` indicates the method of `fun` to be debugged. Note that debugging is implemented slightly differently for this case, as it uses the trace machinery, rather than the debugging bit. As such, `text` and `condition`

cannot be specified in combination with a non-null signature. For methods which implement the `.local` rematching mechanism, the `.local` closure itself is the one that will be ultimately debugged (see [isRematched](#)).

`isdebugged` returns TRUE if a) signature is NULL and the closure fun has been debugged, or b) signature is not NULL, fun is an S4 generic, and the method of fun for that signature has been debugged. In all other cases, it returns FALSE.

The number of lines printed for the deparsed call when a function is entered for debugging can be limited by setting `options` (`deparse.max.lines`).

When debugging is enabled on a byte compiled function then the interpreted version of the function will be used until debugging is disabled.

Value

`debug` and `undebug` invisibly return NULL.

`isdebugged` returns TRUE if the function or method is marked for debugging, and FALSE otherwise.

See Also

[debugcall](#) for conveniently debugging methods, [browser](#) notably for its ‘*commands*’, [trace](#); [traceback](#) to see the stack after an `Error: ...` message; [recover](#) for another debugging approach.

Examples

```
## Not run:
debug(library)
library(methods)

## End(Not run)
## Not run:
debugonce(sample)
## only the first call will be debugged
sample(10, 1)
sample(10, 1)

## End(Not run)
```

declare

Declarations

Description

A framework for specifying information about R code for use by the interpreter, compiler, and code analysis tools.

Usage

```
declare(...)
```

Arguments

... declaration expressions.

Details

A syntax for declaration expressions is still being developed.

Value

Evaluating a `declare()` call ignores the arguments and returns `NULL` invisibly.

Defunct	<i>Marking Objects as Defunct</i>
---------	-----------------------------------

Description

When a function is removed from **R** it should be replaced by a function which calls `.Defunct`.

Usage

```
.Defunct(new, package = NULL, msg)
```

Arguments

<code>new</code>	character string: A suggestion for a replacement function.
<code>package</code>	character string: The package to be used when suggesting where the defunct function might be listed.
<code>msg</code>	character string: A message to be printed, if missing a default message is used.

Details

`.Defunct` is called from defunct functions. These should be listed in `help("pkg-defunct")` for an appropriate *pkg*, including **base**. The alias of the defunct function is added to the same file.

`.Defunct` signals an error of class `"defunctError"` with fields `old`, `new`, and `package`.

See Also

[Deprecated.](#)

`help("base-defunct")` and so on which list the defunct functions in the packages.

delayedAssign	<i>Delay Evaluation and Promises</i>
---------------	--------------------------------------

Description

`delayedAssign` creates a *promise* to evaluate the given expression if its value is requested. This provides direct access to the *lazy evaluation* mechanism used by R for the evaluation of (interpreted) functions.

Usage

```
delayedAssign(x, value, eval.env = parent.frame(1),
              assign.env = parent.frame(1))
```

Arguments

<code>x</code>	a variable name (given as a quoted string in the function call)
<code>value</code>	an expression to be assigned to <code>x</code>
<code>eval.env</code>	an environment in which to evaluate <code>value</code>
<code>assign.env</code>	an environment in which to assign <code>x</code>

Details

Both `eval.env` and `assign.env` default to the currently active environment.

The expression assigned to a promise by `delayedAssign` will not be evaluated until it is eventually ‘forced’. This happens when the variable is first accessed.

When the promise is eventually forced, it is evaluated within the environment specified by `eval.env` (whose contents may have changed in the meantime). After that, the value is fixed and the expression will not be evaluated again, where the promise still keeps its expression.

Value

This function is invoked for its side effect, which is assigning a promise to evaluate `value` to the variable `x`.

See Also

[substitute](#), to see the expression associated with a promise, if `assign.env` is not the `.GlobalEnv`.

Examples

```
msg <- "old"
delayedAssign("x", msg)
substitute(x) # shows only 'x', as it is in the global env.
msg <- "new!"
x # new!

delayedAssign("x", {
  for(i in 1:3)
    cat("yippee!\n")
})
```

```

    10
  })

x^2 #- yippee
x^2 #- simple number

ne <- new.env()
delayedAssign("x", pi + 2, assign.env = ne)
## See the promise {without "forcing" (i.e. evaluating) it}:
substitute(x, ne) # 'pi + 2'

### Promises in an environment [for advanced users]: -----

e <- (function(x, y = 1, z) environment())(cos, "y", {cat(" HO!\n"); pi+2})
## How can we look at all promises in an env (w/o forcing them)?
gete <- function(e_) {
  ne <- names(e_)
  names(ne) <- ne
  lapply(lapply(ne, as.name),
         function(n) eval(substitute(substitute(X, e_), list(X=n))))
}
(exps <- gete(e))
sapply(exps, typeof)

(le <- as.list(e)) # evaluates ("force"s) the promises
stopifnot(identical(le, lapply(exps, eval))) # and another "Ho!"

```

deparse

*Expression Deparsing***Description**

Turn unevaluated expressions into character strings.

Usage

```

deparse(expr, width.cutoff = 60L,
        backtick = mode(expr) %in% c("call", "expression", "(", "function"),
        control = c("keepNA", "keepInteger", "niceNames", "showAttributes"),
        nlines = -1L)

deparse1(expr, collapse = " ", width.cutoff = 500L, ...)

```

Arguments

<code>expr</code>	any R expression.
<code>width.cutoff</code>	integer in [20,500] determining the cutoff (in bytes) at which line-breaking is tried.
<code>backtick</code>	logical indicating whether symbolic names should be enclosed in backticks if they do not follow the standard syntax.
<code>control</code>	character vector (or NULL) of deparsing options. <code>control = "all"</code> is thorough, see .deparseOpts .

<code>nlines</code>	integer: the maximum number of lines to produce. Negative values indicate no limit.
<code>collapse</code>	a string, passed to <code>paste()</code> .
<code>...</code>	further arguments passed to <code>deparse()</code> .

Details

These functions turn unevaluated expressions (where ‘expression’ is taken in a wider sense than the strict concept of a vector of `mode` and type (`typeof`) "expression" used in `expression()`) into character strings (a kind of inverse to `parse`).

A typical use of this is to create informative labels for data sets and plots. The example shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

The default for the `backtick` option is not to quote single symbols but only composite expressions. This is a compromise to avoid breaking existing code.

`width.cutoff` is a lower bound for the line lengths: deparsing a line proceeds until at least `width.cutoff` bytes have been output and e.g. `arg = value` expressions will not be split across lines.

`deparse1()` is a simple utility added in R 4.0.0 to ensure a string result (`character` vector of length one), typically used in name construction, as `deparse1(substitute(.))`.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be deparsed as an attribute.

Deparsing internal structures may not be accurate: for example the graphics display list recorded by `recordPlot` is not intended to be deparsed and `.Internal` calls will be shown as primitive calls.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`.deparseOpts` for available control settings; `dput()` and `dump()` for related functions using identical internal deparsing functionality.

`substitute`, `parse`, `expression`.

Quotes for quoting conventions, including backticks.

Examples

```
require(stats); require(graphics)

deparse(args(lm))
deparse(args(lm), width.cutoff = 500)

myplot <- function(x, y) {
  plot(x, y, xlab = deparse1(substitute(x)),
       ylab = deparse1(substitute(y)))
}
```

```

}

e <- quote(`foo bar`)
deparse(e)
deparse(e, backtick = TRUE)
e <- quote(`foo bar`+1)
deparse(e)
deparse(e, control = "all") # wraps it w/ quote( . )

```

deparseOpts

Options for Expression Deparsing

Description

Process the deparsing options for `deparse`, `dput` and `dump`.

Usage

```

.deparseOpts(control)

..deparseOpts

```

Arguments

`control` character vector of deparsing options.

Details

`..deparseOpts` is the `character` vector of possible deparsing options used by `deparseOpts()`.

`deparseOpts()` is called by `deparse`, `dput` and `dump` to process their `control` argument.

The `control` argument is a vector containing zero or more of the following strings (exactly those in `..deparseOpts`). Partial string matching is used.

"keepInteger": Either surround integer vectors by `as.integer()` or use suffix `L`, so they are not converted to type `double` when parsed. This includes making sure that integer NAs are preserved (via `NA_integer_` if there are no non-NA values in the vector, unless `"S_compatible"` is set).

"quoteExpressions": Surround unevaluated expressions, but not `formulas`, with `quote()`, so they are not evaluated when re-parsed.

"showAttributes": If the object has `attributes` (other than a `source` attribute, see `srcref`), use `structure()` to display them as well as the object value unless the only such attribute is `names` and the `"niceNames"` option is set. This (`"showAttributes"`) is the default for `deparse` and `dput`.

"useSource": If the object has a `source` attribute (`srcref`), display that instead of deparsing the object. Currently only applies to function definitions.

"warnIncomplete": Some exotic objects such as `environments`, external pointers, etc. can not be deparsed properly. This option causes a warning to be issued if the deparser recognizes one of these situations.

Also, the parser in R < 2.7.0 would only accept strings of up to 8192 bytes, and this option gives a warning for longer strings.

- "keepNA": Integer, real and character NAs are surrounded by coercion functions where necessary to ensure that they are parsed to the same type. Since e.g. `NA_real_` can be output in R, this is mainly used in connection with `S_compatible`.
- "niceNames": If true, `lists` and atomic vectors with non-NA names (see `names`) are deparsed as e.g., `c(A = 1)` instead of `structure(1, names = "A")`, independently of the `"showAttributes"` setting.
- "all": An abbreviated way to specify all of the options listed above *plus* `"digits17"`. This is the default for `dump`, and, without `"digits17"`, the options used by `edit` (which are fixed).
- "delayPromises": Deparse promises in the form `<promise: expression>` rather than evaluating them. The value and the environment of the promise will not be shown and the deparsed code cannot be sourced.
- "S_compatible": Make deparsing as far as possible compatible with S and R < 2.5.0. For compatibility with S, integer values of double vectors are deparsed with a trailing decimal point. Backticks are not used.
- "hexNumeric": Real and finite complex numbers are output in `"%a"` format as binary fractions (coded as hexadecimal: see `sprintf`) with maximal opportunity to be recorded exactly to full precision. Complex numbers with one or both non-finite components are output as if this option were not set.
(This relies on that format being correctly supported: known problems on Windows are worked around as from R 3.1.2.)
- "digits17": Real and finite complex numbers are output using format `"%.17g"` which may give more precision than the default (but the output will depend on the platform and there may be loss of precision when read back). Complex numbers with one or both non-finite components are output as if this option were not set.
- "exact": An abbreviated way to specify `control = c("all", "hexNumeric")` which is guaranteed to be exact for numbers, see also below.

For the most readable (but perhaps incomplete) display, use `control = NULL`. This displays the object's value, but not its attributes. The default in `deparse` is to display the attributes as well, but not to use any of the other options to make the result parseable. (`dump` uses more default options via `control = "all"`, and printing of functions without sources uses `c("keepInteger", "keepNA")` to which one may add `"warnIncomplete"`.)

Using `control = "exact"` (short for `control = c("all", "hexNumeric")`) comes closest to making `deparse()` an inverse of `parse()` (but we have not yet seen an example where `"all"`, now including `"digits17"`, would not have been as good). However, not all objects are deparse-able even with these options, and a warning will be issued if the function recognizes that it is being asked to do the impossible.

Only one of `"hexNumeric"` and `"digits17"` can be specified.

Value

An integer value corresponding to the `control` options selected.

Examples

```
stopifnot(.deparseOpts("exact") == .deparseOpts(c("all", "hexNumeric")))
(iOpt.all <- .deparseOpts("all")) # a four digit integer

## one integer --> vector binary bits
int2bits <- function(x, base = 2L,
```

```

        ndigits = 1 + floor(1e-9 + log(max(x,1), base))) {
  r <- numeric(ndigits)
  for (i in ndigits:1) {
    r[i] <- x%%base
    if (i > 1L)
      x <- x/%base
  }
  rev(r) # smallest bit at left
}
int2bits(iOpt.all)
## What options does "all" contain ? =====
(dep0.indiv <- setdiff(..deparseOpts, c("all", "exact")))
(oa <- dep0.indiv[int2bits(iOpt.all) == 1]) # 8 strings
stopifnot(identical(iOpt.all, .deparseOpts(oa)))

## ditto for "exact" instead of "all":
(iOpt.X <- .deparseOpts("exact"))
data.frame(opts = dep0.indiv,
           all = int2bits(iOpt.all),
           exact= int2bits(iOpt.X))
(oX <- dep0.indiv[int2bits(iOpt.X) == 1]) # 8 strings, too
diffXall <- oa != oX
stopifnot(identical(iOpt.X, .deparseOpts(oX)),
          identical(oX[diffXall], "hexNumeric"),
          identical(oa[diffXall], "digits17"))

```

 Deprecated

Marking Objects as Deprecated

Description

When an object is about to be removed from R it is first deprecated and should include a call to `.Deprecated`.

Usage

```

.Deprecated(new, package = NULL, msg,
            old = as.character(sys.call(sys.parent()))[1L])

```

Arguments

<code>new</code>	character string: A suggestion for a replacement function.
<code>package</code>	character string: The package to be used when suggesting where the deprecated function might be listed.
<code>msg</code>	character string: A message to be printed, if missing a default message is used.
<code>old</code>	character string specifying the function (default) or usage which is being deprecated.

Details

`.Deprecated("new name")` is called from deprecated functions. These should be listed in `help("pkg-deprecated")` for an appropriate *pkg*, including **base**. The original help page for a deprecated function is sometimes available at `help("old-deprecated")` (note the quotes).

`.Deprecated` signals a warning of class `"deprecatedWarning"` with fields `old`, `new`, and `package`.

See Also

[Defunct](#)

`help("base-deprecated")` and so on which list the deprecated functions in the packages.

det	<i>Calculate the Determinant of a Matrix</i>
-----	--

Description

`det` calculates the determinant of a matrix. `determinant` is a generic function that returns separately the modulus of the determinant, optionally on the logarithm scale, and the sign of the determinant.

Usage

```
det(x, ...)
determinant(x, logarithm = TRUE, ...)
```

Arguments

<code>x</code>	numeric matrix: logical matrices are coerced to numeric.
<code>logarithm</code>	logical; if <code>TRUE</code> (default) return the logarithm of the modulus of the determinant.
<code>...</code>	optional arguments, currently unused.

Details

The `determinant` function uses an LU decomposition and the `det` function is simply a wrapper around a call to `determinant`.

Often, computing the determinant is *not* what you should be doing to solve a given problem.

Value

For `det`, the determinant of `x`. For `determinant`, a list with components

<code>modulus</code>	a numeric value. The modulus (absolute value) of the determinant if <code>logarithm</code> is <code>FALSE</code> ; otherwise the logarithm of the modulus.
<code>sign</code>	integer; either <code>+1</code> or <code>-1</code> according to whether the determinant is positive or negative.

Examples

```
(x <- matrix(1:4, ncol = 2))
unlist(determinant(x))
det(x)

det(print(cbind(1, 1:3, c(2,0,1))))
```

detach

Detach Objects from the Search Path

Description

Detach a database, i.e., remove it from the `search()` path of available R objects. Usually this is either a `data.frame` which has been *attached* or a package which was attached by `library`.

Usage

```
detach(name, pos = 2L, unload = FALSE, character.only = FALSE,
       force = FALSE)
```

Arguments

<code>name</code>	the object to detach. Defaults to <code>search()[pos]</code> . This can be an unquoted name or a character string but <i>not</i> a character vector. If a number is supplied this is taken as <code>pos</code> .
<code>pos</code>	index position in <code>search()</code> of the database to detach. When <code>name</code> is a number, <code>pos = name</code> is used.
<code>unload</code>	a logical value indicating whether or not to attempt to unload the namespace when a package is being detached. If the package has a namespace and <code>unload</code> is <code>TRUE</code> , then <code>detach</code> will attempt to unload the namespace <i>via</i> <code>unloadNamespace</code> : if the namespace is imported by another namespace or <code>unload</code> is <code>FALSE</code> , no unloading will occur.
<code>character.only</code>	a logical indicating whether <code>name</code> can be assumed to be a character string.
<code>force</code>	logical: should a package be detached even though other attached packages depend on it?

Details

This is most commonly used with a single number argument referring to a position on the search list, and can also be used with a unquoted or quoted name of an item on the search list such as `package:tools`.

If a package has a namespace, detaching it does not by default unload the namespace (and may not even with `unload = TRUE`), and detaching will not in general unload any dynamically loaded compiled code (DLLs); see `getLoadedDLLs` and `library.dynam.unload`. Further, registered S3 methods from the namespace will not be removed, and because S3 methods are not tagged to their source on registration, it is in general not possible to safely un-register the methods associated with a given package. If you use `library` on a package whose namespace is loaded, it attaches the exports of the already loaded namespace. So detaching and re-attaching a package may not refresh some or all components of the package, and is inadvisable. The most reliable way to completely detach a package is to restart R.

Value

The return value is [invisible](#). It is NULL when a package is detached, otherwise the environment which was returned by [attach](#) when the object was attached (incorporating any changes since it was attached).

Good practice

`detach()` without an argument removes the first item on the search path after the workspace. It is all too easy to call it too many or too few times, or to not notice that the search path has changed since an [attach](#) call.

Use of `attach/detach` is best avoided in functions (see the help for [attach](#)) and in interactive use and scripts it is prudent to detach by name.

Note

You cannot detach either the workspace (position 1) nor the **base** package (the last item in the search list), and attempting to do so will throw an error.

Unloading some namespaces has undesirable side effects: e.g. unloading **grid** closes all graphics devices, and on some systems **tcltk** cannot be reloaded once it has been unloaded and may crash R if this is attempted.

Examples

```
require(splines) # package
detach(package:splines)
## or also
library(splines)
pkg <- "package:splines"

detach(pkg, character.only = TRUE)

## careful: do not do this unless 'splines' is not already attached.
library(splines)
detach(2) # 'pos' used for 'name'

## an example of the name argument to attach
## and of detaching a database named by a character vector
attach_and_detach <- function(db, pos = 2)
{
  name <- deparse1(substitute(db))
  attach(db, pos = pos, name = name)
  print(search()[pos])
  detach(name, character.only = TRUE)
}
attach_and_detach(women, pos = 3)
```

diag

*Matrix Diagonals***Description**

Extract or replace the diagonal of a matrix, or construct a diagonal matrix.

Usage

```
diag(x = 1, nrow, ncol, names = TRUE)
diag(x) <- value
```

Arguments

<code>x</code>	a matrix, vector or 1D array , or missing.
<code>nrow, ncol</code>	optional dimensions for the result when <code>x</code> is not a matrix.
<code>names</code>	(when <code>x</code> is a matrix) logical indicating if the resulting vector, the diagonal of <code>x</code> , should inherit names from <code>dimnames(x)</code> if available.
<code>value</code>	either a single value or a vector of length equal to that of the current diagonal. Should be of a mode which can be coerced to that of <code>x</code> .

Details

`diag` has four distinct usages:

1. `x` is a matrix, when it extracts the diagonal.
2. `x` is missing and `nrow` is specified, it returns an identity matrix.
3. `x` is a scalar (length-one vector) and the only argument, it returns a square identity matrix of size given by the scalar.
4. `x` is a ‘numeric’ ([complex](#), numeric, integer, [logical](#), or [raw](#)) vector, either of length at least 2 or there were further arguments. This returns a matrix with the given diagonal and zero off-diagonal entries.

It is an error to specify `nrow` or `ncol` in the first case.

Value

If `x` is a matrix then `diag(x)` returns the diagonal of `x`. The resulting vector will have [names](#) if `names` is true and if the matrix `x` has matching column and rownames.

The replacement form sets the diagonal of the matrix `x` to the given value(s).

In all other cases the value is a diagonal matrix with `nrow` rows and `ncol` columns (if `ncol` is not given the matrix is square). Here `nrow` is taken from the argument if specified, otherwise inferred from `x`: if that is a vector (or 1D array) of length two or more, then its length is the number of rows, but if it is of length one and neither `nrow` nor `ncol` is specified, `nrow = as.integer(x)`.

When a diagonal matrix is returned, the diagonal elements are one except in the fourth case, when `x` gives the diagonal elements: it will be recycled or truncated as needed, but fractional recycling and truncation will give a warning.

Note

Using `diag(x)` can have unexpected effects if `x` is a vector that could be of length one. Use `diag(x, nrow = length(x))` for consistent behaviour.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`upper.tri`, `lower.tri`, `matrix`.

Examples

```
dim(diag(3))
diag(10, 3, 4) # guess what?
all(diag(1:3) == {m <- matrix(0,3,3); diag(m) <- 1:3; m})

## other "numeric"-like diagonal matrices :
diag(c(1i,2i))      # complex
diag(TRUE, 3)       # logical
diag(as.raw(1:3))   # raw
(D2 <- diag(2:1, 4)); typeof(D2) # "integer"

require(stats)
## diag(<var-cov-matrix>) = variances
diag(var(M <- cbind(X = 1:5, Y = rnorm(5))))
#-> vector with names "X" and "Y"
rownames(M) <- c(colnames(M), rep("", 3))
M; diag(M) # named as well
diag(M, names = FALSE) # w/o names
```

diff

Lagged Differences

Description

Returns suitably lagged and iterated differences.

Usage

```
diff(x, ...)
```

```
## Default S3 method:
diff(x, lag = 1, differences = 1, ...)
```

```
## S3 method for class 'POSIXt'
diff(x, lag = 1, differences = 1, ...)
```

```
## S3 method for class 'Date'
diff(x, lag = 1, differences = 1, ...)
```

Arguments

<code>x</code>	a numeric vector or matrix containing the values to be differenced.
<code>lag</code>	an integer indicating which lag to use.
<code>differences</code>	an integer indicating the order of the difference.
<code>...</code>	further arguments to be passed to or from methods.

Details

`diff` is a generic function with a default method and ones for classes `"ts"`, `"POSIXt"` and `"Date"`.

[NA](#)'s propagate.

Value

If `x` is a vector of length `n` and `differences = 1`, then the computed result is equal to the successive differences `x[(1+lag):n] - x[1:(n-lag)]`.

If `differences` is larger than one this algorithm is applied recursively to `x`. Note that the returned value is a vector which is shorter than `x`.

If `x` is a matrix then the difference operations are carried out on each column separately.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[diff.ts](#), [diffinv](#).

Examples

```
diff(1:10, 2)
diff(1:10, 2, 2)
x <- cumsum(cumsum(1:10))
diff(x, lag = 2)
diff(x, differences = 2)

diff(.leap.seconds)
## allows to pass units via ... to difftime()
diff(.leap.seconds, units = "weeks")
diff(as.Date(.leap.seconds), units = "weeks")
```

difftime

*Time Intervals / Differences***Description**

Time intervals creation, printing, and some arithmetic. The `print()` method calls these “time differences”.

Usage

```
time1 - time2

difftime(time1, time2, tz,
         units = c("auto", "secs", "mins", "hours",
                  "days", "weeks"))

as.difftime(tim, format = "%X", units = "auto", tz = "UTC")

## S3 method for class 'difftime'
format(x, ..., with.units = TRUE)
## S3 method for class 'difftime'
units(x)
## S3 replacement method for class 'difftime'
units(x) <- value
## S3 method for class 'difftime'
as.double(x, units = "auto", ...)

## Group methods, notably for round(), signif(), floor(),
## ceiling(), trunc(), abs(); called directly, not as Math():
## S3 method for class 'difftime'
Math(x, ...)
```

Arguments

<code>time1, time2</code>	date-time or date objects.
<code>tz</code>	an optional time zone specification to be used for the conversion, mainly for "POSIXlt" objects.
<code>units</code>	character string. Units in which the results are desired. Can be abbreviated.
<code>value</code>	character string. Like <code>units</code> , except that abbreviations are not allowed.
<code>tim</code>	character string or numeric value specifying a time interval.
<code>format</code>	character specifying the format of <code>tim</code> : see strptime . The default is a locale-specific time format.
<code>x</code>	an object inheriting from class "difftime".
<code>...</code>	arguments to be passed to or from other methods.
<code>with.units</code>	(for the <code>format()</code> method:) logical indicating the units should be part, e.g., "3.5 hours"; if false, the units are suppressed.

Details

Function `difftime` calculates a difference of two date/time objects, `time1` (end) and `time2` (beginning), and returns an object of class `"difftime"` with an attribute indicating the units. The `Math` group method provides `round`, `signif`, `floor`, `ceiling`, `trunc`, `abs`, and `sign` methods for objects of this class, and there are methods for the group-generic (see `Ops`) logical and arithmetic operations.

If `units = "auto"`, a suitable set of units is chosen, the largest possible (excluding `"weeks"`) in which all the absolute differences are greater than one.

Subtraction of date-time objects gives an object of this class, by calling `difftime` with `units = "auto"`. Alternatively, `as.difftime()` works on character-coded or numeric time intervals; in the latter case, units must be specified, and `format` has no effect.

Limited arithmetic is available on `"difftime"` objects: they can be added or subtracted, and multiplied or divided by a numeric vector. In addition, adding or subtracting a numeric vector by a `"difftime"` object implicitly converts the numeric vector to a `"difftime"` object with the same units as the `"difftime"` object. There are methods for `mean` and `sum` (via the `Summary` group generic), and `diff` via `diff.default` building on the `"difftime"` method for arithmetic, notably `-`.

The units of a `"difftime"` object can be extracted by the `units` function, which also has a replacement form. If the units are changed, the numerical value is scaled accordingly. The replacement version keeps attributes such as names and dimensions.

Note that `units = "days"` means a period of 24 hours, hence takes no account of Daylight Savings Time. Differences in objects of class `"Date"` are computed as if in the UTC time zone.

The `as.double` method returns the numeric value expressed in the specified units. Using `units = "auto"` means the units of the object.

The `format` method simply formats the numeric value and appends the units as a text string.

Warning

Because `R` follows POSIX (and almost all computer clocks) in ignoring leap seconds, so do time differences. So in a UTC time zone

```
z <- as.POSIXct(c("2016-12-31 23:59:59", "2017-01-01 00:00:01"))
z[2] - z[1]
```

reports 'Time difference of 2 secs' but 3 seconds elapsed while the computer clock advanced by 2 seconds.

If you want the elapsed time interval, you need to add in any leap seconds for yourself.

Note

Units such as `"months"` are not possible as they are not of constant length. To create intervals of months, quarters or years use `seq.Date` or `seq.POSIXt`.

See Also

[DateTimeClasses](#).

Examples

```
(z <- Sys.time() - 3600)
Sys.time() - z           # just over 3600 seconds.

## time interval between release days of R 1.2.2 and 1.2.3.
ISOdate(2001, 4, 26) - ISOdate(2001, 2, 26)

as.difftime(c("0:3:20", "11:23:15"))
as.difftime(c("3:20", "23:15", "2:"), format = "%H:%M") # 3rd gives NA
(z <- as.difftime(c(0,30,60), units = "mins"))
as.numeric(z, units = "secs")
as.numeric(z, units = "hours")
format(z)
```

dim	<i>Dimensions of an Object</i>
-----	--------------------------------

Description

Retrieve or set the dimension of an object.

Usage

```
dim(x)
dim(x) <- value
```

Arguments

x	an R object, for example a matrix, array or data frame.
value	for the default method, either NULL or a numeric vector, which is coerced to integer (by truncation).

Details

The functions `dim` and `dim<-` are [internal generic primitive](#) functions.

`dim` has a method for [data.frames](#), which returns the lengths of the `row.names` attribute of `x` and of `x` (as the numbers of rows and columns respectively).

Value

For an array (and hence in particular, for a matrix) `dim` retrieves the `dim` attribute of the object. It is NULL or a vector of mode [integer](#).

The replacement method changes the "dim" attribute (provided the new value is compatible) and removes any "dimnames" *and* "names" attributes.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[ncol](#), [nrow](#) and [dimnames](#).

Examples

```
x <- 1:12 ; dim(x) <- c(3,4)
x

# simple versions of nrow and ncol could be defined as follows
nrow0 <- function(x) dim(x)[1]
ncol0 <- function(x) dim(x)[2]
```

dimnames

Dimnames of an Object

Description

Retrieve or set the dimnames of an object.

Usage

```
dimnames(x)
dimnames(x) <- value

provideDimnames(x, sep = "", base = list(. = LETTERS), unique = TRUE,
              use.names = FALSE)
```

Arguments

<code>x</code>	an R object, for example a matrix, array or data frame.
<code>value</code>	a possible value for <code>dimnames(x)</code> : see the ‘Value’ section.
<code>sep</code>	a character string, used to separate <code>base</code> symbols and digits in the constructed dimnames.
<code>base</code>	a non-empty list of character vectors. The list components are used in turn (and recycled when needed) to construct replacements for empty dimnames components. See also the examples.
<code>unique</code>	logical indicating that the dimnames constructed are unique within each dimension in the sense of make.unique .
<code>use.names</code>	a logical indicating if <code>names(base)</code> is used to replace empty elements of <code>names(dimnames(x))</code> . If <code>TRUE</code> , then <code>unique</code> and <code>sep</code> apply to the constructed names, as well.

Details

The functions `dimnames` and `dimnames<-` are generic.

For an [array](#) (and hence in particular, for a [matrix](#)), they retrieve or set the `dimnames` attribute (see [attributes](#)) of the object. A list value can have names, and these will be used to label the dimensions of the array where appropriate.

The replacement method for arrays/matrices coerces vector and factor elements of `value` to character, but does not dispatch methods for `as.character`. It coerces zero-length elements to

NULL, and a zero-length list to NULL. If `value` is a list shorter than the number of dimensions, it is extended with NULLs to the needed length.

Both have methods for data frames. The dimnames of a data frame are its `row.names` and its `names`. For the replacement method each component of `value` will be coerced by `as.character`.

For a 1D matrix the `names` are the same thing as the (only) component of the dimnames.

Both are `primitive` functions.

`provideDimnames(x)` provides dimnames where “missing”, such that its result has `character` dimnames for each component. If `unique` is true as by default, they are unique within each component via `make.unique(*, sep=sep)`.

Value

The dimnames of a matrix or array can be NULL (which is not stored) or a list of the same length as `dim(x)`. If a list, its components are either NULL or a character vector with positive length of the appropriate dimension of `x`. The list can have names. It is possible that all components are NULL: such dimnames may get converted to NULL.

For the `"data.frame"` method both dimnames are character vectors, and the rownames must contain no duplicates nor missing values.

`provideDimnames(x)` returns `x`, with “NULL - free” dimnames, i.e. each component a character vector of correct length.

Note

Setting components of the dimnames, e.g., `dimnames(A)[[1]] <- value` is a common paradigm, but note that it will not work if the value assigned is NULL. Use `rownames` instead, or (as it does) manipulate the whole dimnames list.

`rownames`, `colnames`; `array`, `matrix`, `data.frame`.

Examples

```
## simple versions of rownames and colnames
## could be defined as follows
rownames0 <- function(x) dimnames(x)[[1]]
colnames0 <- function(x) dimnames(x)[[2]]

(dn <- dimnames(A <- provideDimnames(N <- array(1:24, dim = 2:4))))
A0 <- A; dimnames(A)[2:3] <- list(NULL)
stopifnot(identical(A0, provideDimnames(A)))
strd <- function(x) utils::str(dimnames(x))
strd(provideDimnames(A, base= list(letters[-(1:9)], tail(LETTERS))))
strd(provideDimnames(N, base= list(letters[-(1:9)], tail(LETTERS)))) # recycling
strd(provideDimnames(A, base= list(c("AA","BB")))) # recycling on both levels
## set "empty dimnames":
provideDimnames(rbind(1, 2:3), base = list(""), unique=FALSE)
```

```
## optionally handling names(dimnames(.))
L3 <- structure(vector("list", 3L), names = c("", "~~", ""))
strd(N3 <- structure(N, dimnames = L3))
strd(provideDimnames(N3, use.names = TRUE, unique = FALSE))
strd(provideDimnames(N3, use.names = TRUE))
```

do.call

*Execute a Function Call***Description**

`do.call` constructs and executes a function call from a name or a function and a list of arguments to be passed to it.

Usage

```
do.call(what, args, quote = FALSE, envir = parent.frame())
```

Arguments

<code>what</code>	either a function or a non-empty character string naming the function to be called.
<code>args</code>	a <i>list</i> of arguments to the function call. The <code>names</code> attribute of <code>args</code> gives the argument names.
<code>quote</code>	a logical value indicating whether to quote the arguments.
<code>envir</code>	an environment within which to evaluate the call. This will be most useful if <code>what</code> is a character string and the arguments are symbols or quoted expressions.

Details

If `quote` is `FALSE`, the default, then the arguments are evaluated (in the calling environment, not in `envir`). If `quote` is `TRUE` then each argument is quoted (see [quote](#)) so that the effect of argument evaluation is to remove the quotes – leaving the original arguments unevaluated when the call is constructed.

The behavior of some functions, such as [substitute](#), will not be the same for functions evaluated using `do.call` as if they were evaluated from the interpreter. The precise semantics are currently undefined and subject to change.

Value

The result of the (evaluated) function call.

Warning

This should not be used to attempt to evade restrictions on the use of `.Internal` and other non-API calls.

[call](#) which creates an unevaluated call.

Examples

```
do.call("complex", list(imaginary = 1:3))

## if we already have a list (e.g., a data frame)
## we need c() to add further arguments
tmp <- expand.grid(letters[1:2], 1:3, c("+", "-"))
do.call("paste", c(tmp, sep = ""))

do.call(paste, list(as.name("A"), as.name("B")), quote = TRUE)

## examples of where objects will be found.
A <- 2
f <- function(x) print(x^2)
env <- new.env()
assign("A", 10, envir = env)
assign("f", f, envir = env)
f <- function(x) print(x)
f(A) # 2
do.call("f", list(A)) # 2
do.call("f", list(A), envir = env) # 4
do.call(f, list(A), envir = env) # 2
do.call("f", list(quote(A)), envir = env) # 100
do.call(f, list(quote(A)), envir = env) # 10
do.call("f", list(as.name("A")), envir = env) # 100

eval(call("f", A)) # 2
eval(call("f", quote(A))) # 2
eval(call("f", A), envir = env) # 4
eval(call("f", quote(A)), envir = env) # 100
```

dontCheck

Identity Function to Suppress Checking

Description

The dontCheck function is the same as [identity](#), but is interpreted by R CMD check code analysis as a directive to suppress checking of x. Currently this is only used by [checkFF](#)(registration = TRUE) when checking the .NAME argument of foreign function calls.

Usage

```
dontCheck(x)
```

Arguments

x an R object.

See Also

`suppressForeignCheck` which explains why that and `dontCheck` are undesirable and should be avoided if at all possible.

dots ..., ..1, etc used in Functions

Description

`...` and `..1`, `..2` etc are used to refer to arguments passed down from a calling function. These (and the following) can only be used *inside* a function which has `...` among its formal arguments.

`...elt(n)` is a functional way to get `..n` and basically the same as `eval(paste0("..", n))`, just more elegant and efficient. Note that `switch(n, ...)` is very close, differing by returning `NULL` invisibly instead of an error when `n` is zero or too large.

`...length()` returns the number of expressions in `...`, and `...names()` the [names](#). These are the same as `length(list(...))` or `names(list(...))` but without evaluating the expressions in `...` (which happens with `list(...)`).

Evaluating elements of `...` with `..1`, `..2`, `...elt(n)`, etc. propagates [visibility](#). This is consistent with the evaluation of named arguments which also propagates visibility.

Usage

```
...length()
...names()
...elt(n)
```

Arguments

<code>n</code>	a positive integer, not larger than the number of expressions in <code>...</code> , which is the same as <code>...length()</code> which is the same as <code>length(list(...))</code> , but the latter evaluates all expressions in <code>...</code>
----------------	--

See Also

`...` and `..1`, `..2` are *reserved* words in R, see [Reserved](#).

“The `...` argument” in *An Introduction to R*, and `?dotsMethods` for its use in formal (S4) methods.

Examples

```
tst <- function(n, ...) ...elt(n)
tst(1, pi=pi*0:1, 2:4) ## [1] 0.000000 3.141593
tst(2, pi=pi*0:1, 2:4) ## [1] 2 3 4
try(tst(1)) # -> Error about '...' not containing an element.

tst.dl <- function(x, ...) ...length()
tst.dns <- function(x, ...) ...names()
tst.dl(1:10)      # 0 (because the first argument is 'x')
tst.dl(4, 5)      # 1
tst.dl(4, 5, 6)   # 2 namely '5, 6'
tst.dl(4, 5, 6, 7, sin(1:10), "foo"/"bar") # 5.    Note: no evaluation!
```

```
tst.dns(4, foo=5, 6, bar=7, sini = sin(1:10), "foo"/"bar")
##           "foo"      "" "bar"  "sini"           ""

## From R 4.1.0 to 4.1.2, ...names() sometimes did not match names(list(...));
## check and show (these examples all would've failed):
chk.n2 <- function(...) stopifnot(identical(print(...names()), names(list(...))))
chk.n2(4, foo=5, 6, bar=7, sini = sin(1:10), "bar")
chk.n2()
chk.n2(1,2)
```

double

*Double-Precision Vectors***Description**

Create, coerce to or test for a double-precision vector.

Usage

```
double(length = 0)
as.double(x, ...)
is.double(x)

single(length = 0)
as.single(x, ...)
```

Arguments

<code>length</code>	a non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
<code>x</code>	object to be coerced or tested.
<code>...</code>	further arguments passed to or from other methods.

Details

`double` creates a double-precision vector of the specified length. The elements of the vector are all equal to 0. It is identical to `numeric`.

`as.double` is a generic function. It is identical to `as.numeric`. Methods should return an object of base type "double".

`is.double` is a test of double `type`.

R has no single precision data type. All real numbers are stored in double precision format. The functions `as.single` and `single` are identical to `as.double` and `double` except they set the attribute `Csingle` that is used in the `.C` and `.Fortran` interface, and they are intended only to be used in that context.

Value

`double` creates a double-precision vector of the specified length. The elements of the vector are all equal to 0.

`as.double` attempts to coerce its argument to be of double type: like `as.vector` it strips attributes including names. (To ensure that an object is of double type without stripping attributes, use `storage.mode`.) Character strings containing optional whitespace followed by either a decimal representation or a hexadecimal representation (starting with `0x` or `0X`) can be converted, as can special values such as `"NA"`, `"NaN"`, `"Inf"` and `"infinity"`, irrespective of case.

`as.double` for factors yields the codes underlying the factor levels, not the numeric representation of the labels, see also `factor`.

`is.double` returns `TRUE` or `FALSE` depending on whether its argument is of double `type` or not.

Double-precision values

All R platforms are required to work with values conforming to the IEC 60559 (also known as IEEE 754) standard. This basically works with a precision of 53 bits, and represents to that precision a range of absolute values from about 2×10^{-308} to 2×10^{308} . It also has special values `NaN` (many of them), plus and minus infinity and plus and minus zero (although R acts as if these are the same). There are also *denormal(ized)* (or *subnormal*) numbers with values below the range given above but represented to less precision.

See `.Machine` for precise information on these limits. Note that ultimately how double precision numbers are handled is down to the CPU/FPU and compiler.

In IEEE 754-2008/IEC60559:2011 this is called ‘binary64’ format.

Note on names

It is a historical anomaly that R has two names for its floating-point vectors, `double` and `numeric` (and formerly had `real`).

`double` is the name of the `type`. `numeric` is the name of the `mode` and also of the implicit `class`. As an S4 formal class, use `"numeric"`.

The potential confusion is that R has used *mode* `"numeric"` to mean ‘double or integer’, which conflicts with the S4 usage. Thus `is.numeric` tests the mode, not the class, but `as.numeric` (which is identical to `as.double`) coerces to the class.

```
is.double(1)
all(double(3) == 0)
```

dput

Write an Object to a File or Recreate it

Description

Writes an ASCII text representation of an R object to a file, the R console, or a connection, or uses one to recreate the object.

Usage

```
dput(x, file = "",
      control = c("keepNA", "keepInteger", "niceNames", "showAttributes"))

dget(file, keep.source = FALSE)
```

Arguments

<code>x</code>	an object.
<code>file</code>	either a character string naming a file or a connection . "" indicates output to the console.
<code>control</code>	character vector (or NULL) of deparsing options. <code>control = "all"</code> is thorough, see .deparseOpts .
<code>keep.source</code>	logical: should the source formatting be retained when parsing functions, if possible?

Details

`dput` opens `file` and deparses the object `x` into that file. The object name is not written (unlike `dump`). If `x` is a function the associated environment is stripped. Hence scoping information can be lost.

Deparsing an object is difficult, and not always possible. With the default `control`, `dput()` attempts to deparse in a way that is readable, but for more complex or unusual objects (see [dump](#)), not likely to be parsed as identical to the original. Use `control = "all"` for the most complete deparsing; use `control = NULL` for the simplest deparsing, not even including attributes.

`dput` will warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

To display saved source rather than deparsing the internal representation include `"useSource"` in `control`. R currently saves source only for function definitions. If you do not care about source representation (e.g., for a data object), for speed set `options(keep.source = FALSE)` when calling `source`.

Value

For `dput`, the first argument invisibly.

For `dget`, the object created.

Note

This is **not** a good way to transfer objects between R sessions. `dump` is better, but the functions `save` and `saveRDS` are designed to be used for transporting R data, and will work with R objects that `dput` does not handle correctly as well as being much faster.

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be written as an attribute.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`deparse`, `.deparseOpts`, `dump`, `write`.

Examples

```
fil <- tempfile()
## Write an ASCII version of the 'base' function mean() to our temp file, ..
dput(base::mean, fil)
## ... read it back into 'bar' and confirm it is the same
bar <- dget(fil)
stopifnot(all.equal(bar, base::mean, check.environment = FALSE))

## Create a function with comments
baz <- function(x) {
  # Subtract from one
  1-x
}
## and display it
dput(baz)
## and now display the saved source
dput(baz, control = "useSource")

## Numeric values:
xx <- pi^(1:3)
dput(xx)
dput(xx, control = "digits17")
dput(xx, control = "hexNumeric")
dput(xx, fil); dget(fil) - xx # slight rounding on all platforms
dput(xx, fil, control = "digits17")
dget(fil) - xx # slight rounding on some platforms
dput(xx, fil, control = "hexNumeric"); dget(fil) - xx
unlink(fil)

xn <- setNames(xx, paste0("pi^",1:3))
dput(xn) # nicer, now "niceNames" being part of default 'control'
dput(xn, control = "S_compat") # no names
## explicitly asking for output as in R < 3.5.0:
dput(xn, control = c("keepNA", "keepInteger", "showAttributes"))
```

drop

*Drop Redundant Extent Information***Description**

Delete the dimensions of an array which have only one level.

Usage

```
drop(x)
```

Arguments

`x` an array (including a matrix).

Value

If `x` is an object with a `dim` attribute (e.g., a matrix or [array](#)), then `drop` returns an object like `x`, but with any extents of length one removed. Any accompanying `dimnames` attribute is adjusted and returned with `x`: if the result is a vector the names are taken from the `dimnames` (if any). However, if the result is a vector of length one, then it does not get names *unless* exactly one component of the `dimnames` is non-NULL, in which case that component is used.

Array subsetting (`[]`) performs this reduction unless used with `drop = FALSE`, but sometimes it is useful to invoke `drop` directly.

See Also

[drop1](#) which is used for dropping terms in models, and [droplevels](#) used for dropping unused levels from a [factor](#).

Examples

```
dim(drop(array(1:12, dim = c(1,3,1,1,2,1,2)))) # = 3 2 2
drop(1:3 %**% 2:4) # scalar product - w/o drop(.), would return 1x1 matrix

# Behavior when result is length-1 vector:
(x <- x1 <- x2 <- array(0, c(1L, 1L), list("a", "b")))
colnames(x1) <- rownames(x2) <- NULL
names(drop(x)) # NULL
names(drop(x1)) # "a"
names(drop(x2)) # "b"
```

droplevels*Drop Unused Levels from Factors*

Description

The function `droplevels` is used to drop unused levels from a `factor` or, more commonly, from factors in a data frame.

Usage

```
droplevels(x, ...)  
## S3 method for class 'factor'  
droplevels(x, exclude = if(anyNA(levels(x))) NULL else NA, ...)  
## S3 method for class 'data.frame'  
droplevels(x, except, exclude, ...)
```

Arguments

<code>x</code>	an object from which to drop unused factor levels.
<code>exclude</code>	passed to <code>factor()</code> ; factor levels which should be excluded from the result even if present. Note that this was <i>implicitly</i> <code>NA</code> in <code>R <= 3.3.1</code> which did drop <code>NA</code> levels even when present in <code>x</code> , contrary to the documentation. The current default is compatible with <code>x[, drop=TRUE]</code> .
<code>...</code>	further arguments passed to methods.
<code>except</code>	indices of columns from which <i>not</i> to drop levels.

Details

The method for class `"factor"` is currently equivalent to `factor(x, exclude=exclude)`. For the data frame method, you should rarely specify `exclude` “globally” for all factor columns; rather the default uses the same factor-specific `exclude` as the factor method itself.

The `except` argument follows the usual indexing rules.

Value

`droplevels` returns an object of the same class as `x`

Note

This function was introduced in `R 2.12.0`. It is primarily intended for cases where one or more factors in a data frame contains only elements from a reduced level set after subsetting. (Notice that subsetting does *not* in general drop unused levels). By default, levels are dropped from all factors in a data frame, but the `except` argument allows you to specify columns for which this is not wanted.

See Also

`subset` for subsetting data frames. `factor` for definition of factors. `drop` for dropping array dimensions. `drop1` for dropping terms from a model. `[.factor` for subsetting of factors.

Examples

```
aq <- transform(airquality, Month = factor(Month, labels = month.abb[5:9]))
aq <- subset(aq, Month != "Jul")
table(aq$Month)
table(droplevels(aq)$Month)
```

 dump

Text Representations of R Objects

Description

This function takes a vector of names of R objects and produces text representations of the objects on a file or connection. A dump file can usually be [sourced](#) into another R session.

Usage

```
dump(list, file = "dumpdata.R", append = FALSE,
      control = "all", envir = parent.frame(), evaluate = TRUE)
```

Arguments

<code>list</code>	character vector (or <code>NULL</code>). The names of R objects to be dumped.
<code>file</code>	either a character string naming a file or a connection . "" indicates output to the console.
<code>append</code>	if <code>TRUE</code> and <code>file</code> is a character string, output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .
<code>control</code>	character vector (or <code>NULL</code>) indicating deparsing options. See .deparseOpts for their description.
<code>envir</code>	the environment to search for objects.
<code>evaluate</code>	logical. Should promises be evaluated?

Details

If some of the objects named do not exist (in scope), they are omitted, with a warning. If `file` is a character string and no objects exist then no file is created.

[sourcing](#) may not produce an identical copy of dumped objects. A warning is issued if it is likely that problems will arise, for example when dumping exotic or complex objects (see the Note).

dump will also warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

A dump file can be [sourced](#) into another R (or perhaps S) session, but the functions [save](#) and [saveRDS](#) are designed to be used for transporting R data, and will work with R objects that dump does not handle. For maximal reproducibility use `control = "exact"`.

To produce a more readable representation of an object, use `control = NULL`. This will skip attributes, and will make other simplifications that make [source](#) less likely to produce an identical copy. See [.deparseOpts](#) for details.

To deparse the internal representation of a function rather than displaying the saved source, use `control = c("keepInteger", "warnIncomplete", "keepNA")`. This will lose all

formatting and comments, but may be useful in those cases where the saved source is no longer correct.

Promises will normally only be encountered by users as a result of lazy-loading (when the default `evaluate = TRUE` is essential) and after the use of `delayedAssign`, when `evaluate = FALSE` might be intended.

Value

An invisible character vector containing the names of the objects which were dumped.

Note

As `dump` is defined in the base namespace, the **base** package will be searched *before* the global environment unless `dump` is called from the top level prompt or the `envir` argument is given explicitly.

To avoid the risk of a source attribute becoming out of sync with the actual function definition, the source attribute of a function will never be dumped as an attribute.

Currently environments, external pointers, weak references and objects of type S4 are not deparsed in a way that can be `sourced`. In addition, [language objects](#) are deparsed in a simple way whatever the value of `control`, and this includes not dumping their attributes (which will result in a warning).

References

See Also

[.deparseOpts](#) for available `control` settings; [dput\(\)](#), [dget\(\)](#) and [deparse\(\)](#) for related functions using identical internal deparsing functionality.

[write](#), [write.table](#), etc for “dumping” data to (text) files.

[save](#) and [saveRDS](#) for a more reliable way to save R objects.

Examples

```
x <- 1; y <- 1:10
fil <- tempfile(fileext=".Rdmped")
dump(ls(pattern = '^[xyz]'), fil)
print(.Last.value)
unlink(fil)
```

duplicated

Determine Duplicate Elements

Description

`duplicated()` determines which elements of a vector or data frame are duplicates of elements with smaller subscripts, and returns a logical vector indicating which elements (rows) are duplicates.

`anyDuplicated(.)` is a “generalized” more efficient version of `any(duplicated(.))`, returning positive integer indices instead of just `TRUE`.

Usage

```

duplicated(x, incomparables = FALSE, ...)

## Default S3 method:
duplicated(x, incomparables = FALSE,
           fromLast = FALSE, nmax = NA, ...)

## S3 method for class 'array'
duplicated(x, incomparables = FALSE, MARGIN = 1,
           fromLast = FALSE, ...)

anyDuplicated(x, incomparables = FALSE, ...)
## Default S3 method:
anyDuplicated(x, incomparables = FALSE,
              fromLast = FALSE, ...)
## S3 method for class 'array'
anyDuplicated(x, incomparables = FALSE,
              MARGIN = 1, fromLast = FALSE, ...)

```

Arguments

<code>x</code>	a (generalized, see is.vector) vector, a data frame, an array or NULL.
<code>incomparables</code>	a vector of values that cannot be compared. FALSE is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as <code>x</code> .
<code>fromLast</code>	logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to <code>duplicated = FALSE</code> .
<code>nmax</code>	the maximum number of unique items expected (greater than one).
<code>...</code>	arguments for particular methods.
<code>MARGIN</code>	the array margin to be held fixed: see apply , and note that <code>MARGIN = 0</code> may be useful.

Details

These are generic functions with methods for vectors (including lists and expressions), data frames and arrays (including matrices).

For the default methods, and whenever there are equivalent method definitions for `duplicated` and `anyDuplicated`, `anyDuplicated(x, ...)` is a “generalized” shortcut for `any(duplicated(x, ...))`, in the sense that it returns the *index* `i` of the first duplicated entry `x[i]` if there is one, and 0 otherwise. Their behaviours may be different when at least one of `duplicated` and `anyDuplicated` has a relevant method.

`duplicated(x, fromLast = TRUE)` is equivalent to but faster than `rev(duplicated(rev(x)))`.

The array method calculates for each element of the sub-array specified by `MARGIN` if the remaining dimensions are identical to those for an earlier (or later, when `fromLast = TRUE`) element (in row-major order). This would most commonly be used to find duplicated rows (the default) or columns (with `MARGIN = 2`). Note that `MARGIN = 0` returns an array of the same dimensionality attributes as `x`.

Missing values ("NA") are regarded as equal, numeric and complex ones differing from NaN; character strings will be compared in a “common encoding”; for details, see [match](#) (and [unique](#)) which use the same concept.

Values in `incomparables` will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

Except for factors, logical and raw vectors the default `nmax = NA` is equivalent to `nmax = length(x)`. Since a hash table of size `8*nmax` bytes is allocated, setting `nmax` suitably can save large amounts of memory. For factors it is automatically set to the smaller of `length(x)` and the number of levels plus one (for NA). If `nmax` is set too small there is liable to be an error: `nmax = 1` is silently ignored.

[Long vectors](#) are supported for the default method of `duplicated`, but may only be usable if `nmax` is supplied.

Value

`duplicated()`: For a vector input, a logical vector of the same length as `x`. For a data frame, a logical vector with one element for each row. For a matrix or array, and when `MARGIN = 0`, a logical array with the same dimensions and `dimnames`.

`anyDuplicated()`: an integer or real vector of length one with value the 1-based index of the first duplicate if any, otherwise 0.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see [vector](#)) or differ only in their attributes. In the worst case it is $O(n^2)$.

```

```
anyDuplicated(x, fromLast = TRUE)
```

dyn.load

Foreign Function Interface

Description

Load or unload DLLs (also known as shared objects), and test whether a C function or Fortran subroutine is available.

Usage

```
dyn.load(x, local = TRUE, now = TRUE, ...)
dyn.unload(x)
```

```
is.loaded(symbol, PACKAGE = "", type = "")
```

Arguments

x	a character string giving the pathname to a DLL, also known as a dynamic shared object. (See ‘Details’ for what these terms mean.)
local	a logical value controlling whether the symbols in the DLL are stored in their own local table and not shared across DLLs, or added to the global symbol table. Whether this has any effect is system-dependent.
now	a logical controlling whether all symbols are resolved (and relocated) immediately when the library is loaded or deferred until they are used. This control is useful for developers testing whether a library is complete and has all the necessary symbols, and for users to ignore missing symbols. Whether this has any effect is system-dependent.
...	other arguments for future expansion.
symbol	a character string giving a symbol name.
PACKAGE	if supplied, confine the search for the name to the DLL given by this argument (plus the conventional extension, ‘.so’, ‘.sl’, ‘.dll’, ...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols. This is used in the same way as in the <code>.C</code> , <code>.Call</code> , <code>.Fortran</code> and <code>.External</code> functions.
type	the type of symbol to look for: can be any (“”, the default), “Fortran”, “Call” or “External”.

Details

The objects `dyn.load` loads are called ‘dynamically loadable libraries’ (abbreviated to ‘DLL’) on all platforms except macOS, which uses the term for a different sort of object. On Unix-alikes they are also called ‘dynamic shared objects’ (‘DSO’), or ‘shared objects’ for short. (The POSIX standards use ‘executable object file’, but no one else does.)

See ‘See Also’ and [Writing R Extensions](#) and [R Installation and Administration](#) for how to create and install a suitable DLL.

Unfortunately some rare platforms (e.g., Compaq Tru64) do not handle the `PACKAGE` argument correctly, and may incorrectly find symbols linked into R.

The additional arguments to `dyn.load` mirror the different aspects of the mode argument to the `dlopen()` routine on POSIX systems. They are available so that users can exercise greater control over the loading process for an individual library. In general, the default values are appropriate and you should override them only if there is good reason and you understand the implications.

The `local` argument allows one to control whether the symbols in the DLL being attached are visible to other DLLs. While maintaining the symbols in their own namespace is good practice, the ability to share symbols across related ‘chapters’ is useful in many cases. Additionally, on certain platforms and versions of an operating system, certain libraries must have their symbols loaded globally to successfully resolve all symbols.

One should be careful of one potential side-effect of using lazy loading via `now = FALSE`: if a routine is called that has a missing symbol, the process will terminate immediately. The intended use is for library developers to call this with value `TRUE` to check that all symbols are actually resolved and for regular users to call it with `FALSE` so that missing symbols can be ignored and the available ones can be called.

The initial motivation for adding these was to avoid such termination in the `_init()` routines of the Java virtual machine library. However, symbols loaded locally may not be (read: probably) available to other DLLs. Those added to the global table are available to all other elements of the application and so can be shared across two different DLLs.

Some (very old) systems do not provide (explicit) support for local/global and lazy/eager symbol resolution. This can be the source of subtle bugs. One can arrange to have warning messages emitted when unsupported options are used. This is done by setting either of the options `verbose` or `warn` to be non-zero via the `options` function.

There is a short discussion of these additional arguments with some example code available at <https://www.stat.ucdavis.edu/~duncan/R/dynload/>.

Value

The function `dyn.load` is used for its side effect which links the specified DLL to the executing R image. Calls to `.C`, `.Call`, `.Fortran` and `.External` can then be used to execute compiled C functions or Fortran subroutines contained in the library. The return value of `dyn.load` is an object of class `DLLInfo`. See `getLoadedDLLs` for information about this class.

The function `dyn.unload` unlinks the DLL. Note that unloading a DLL and then re-loading a DLL of the same name may or may not work: on Solaris it used the first version loaded. Note also that some DLLs cannot be safely unloaded at all: unloading a DLL which implements C finalizers but does not unregister them on unload causes R to crash.

`is.loaded` checks if the symbol name is loaded *and searchable* and hence available for use as a character string value for argument `.NAME` in `.C`, `.Fortran`, `.Call`, or `.External`. It will succeed if any one of the four calling functions would succeed in using the entry point unless `type` is specified. (See `.Fortran` for how Fortran symbols are mapped.) Note that symbols in base packages are not searchable, and other packages can be so marked.

Warning

Do not use `dyn.unload` on a DLL loaded by `library.dynam`: use `library.dynam.unload`. This is needed for system housekeeping.

Note

`is.loaded` requires the name you would give to `.C` etc. It must be a character string and so cannot be an R object as used for registered native symbols (see Section “[Registering native routines](#)” in

Writing R Extensions). Some registered symbols are available by name but most are not, including those in the examples below.

By default, the maximum number of DLLs that can be loaded is now 614 when the OS limit on the number of open files allows or can be increased, but less otherwise (but it will be at least 100). A specific maximum can be requested *via* the environment variable `R_MAX_NUM_DLLS`, which has to be set (to a value between 100 and 1000 inclusive) before starting an R session. If the OS limit on the number of open files does not allow using this maximum and cannot be increased, R will fail to start with an error. The maximum is not allowed to be greater than 60% of the OS limit on the number of open files (essentially unlimited on Windows, on Unix typically 1024, but 256 on macOS). The limit can sometimes (including on macOS) be modified using command `ulimit -n (sh, bash)` or `limit descriptors (csh)` in the shell used to launch R. Increasing `R_MAX_NUM_DLLS` comes with some memory overhead, and be aware that many types of [connections](#) also use file descriptors.

If the OS limit on the number of open files cannot be determined, the DLL limit is 100 and cannot be changed *via* `R_MAX_NUM_DLLS`.

The creation of DLLs and the runtime linking of them into executing programs is very platform dependent. In recent years there has been some simplification in the process because the C subroutine call `dlopen` has become the POSIX standard for doing this. Under Unix-alikes `dyn.load` uses the `dlopen` mechanism and should work on all platforms which support it. On Windows it uses the standard mechanism (`LoadLibrary`) for loading DLLs.

The original code for loading DLLs in Unix-alikes was provided by Heiner Schwarte.

is.loaded("supsmu", "stats", "Fortran")
is.loaded("PDF", type = "External") # pdf() device in grDevices
```

eapply

Apply a Function Over Values in an Environment

Description

`eapply` applies `FUN` to the named values from an [environment](#) and returns the results as a list. The user can request that all named objects are used (normally names that begin with a dot are not). The output is not sorted and no enclosing environments are searched.

Usage

```
eapply(env, FUN, ..., all.names = FALSE, USE.NAMES = TRUE)
```

Arguments

<code>env</code>	environment to be used.
<code>FUN</code>	the function to be applied, found <i>via</i> <code>match.fun</code> . In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be backquoted or quoted.
<code>...</code>	optional arguments to <code>FUN</code> .
<code>all.names</code>	a logical indicating whether to apply the function to all values.
<code>USE.NAMES</code>	logical indicating whether the resulting list should have <code>names</code> .

Value

A named (unless `USE.NAMES = FALSE`) list. Note that the order of the components is arbitrary for hashed environments.

See Also

`environment`, `lapply`.

Examples

```
require(stats)

env <- new.env(hash = FALSE) # so the order is fixed
env$a <- 1:10
env$beta <- exp(-3:3)
env$logic <- c(TRUE, FALSE, FALSE, TRUE)
# what have we there?
utils::ls.str(env)

# compute the mean for each list element
eapply(env, mean)
unlist(eapply(env, mean, USE.NAMES = FALSE))

# median and quartiles for each element (making use of "..." passing):
eapply(env, quantile, probs = 1:3/4)
eapply(env, quantile)
```

eigen

Spectral Decomposition of a Matrix

Description

Computes eigenvalues and eigenvectors of numeric (double, integer, logical) or complex matrices.

Usage

```
eigen(x, symmetric, only.values = FALSE, EISPACK = FALSE)
```

Arguments

<code>x</code>	a numeric or complex matrix whose spectral decomposition is to be computed. Logical matrices are coerced to numeric.
<code>symmetric</code>	if TRUE, the matrix is assumed to be symmetric (or Hermitian if complex) and only its lower triangle (diagonal included) is used. If <code>symmetric</code> is not specified, <code>isSymmetric(x)</code> is used.
<code>only.values</code>	if TRUE, only the eigenvalues are computed and returned, otherwise both eigenvalues and eigenvectors are returned.
<code>EISPACK</code>	logical. Defunct and ignored.

Details

If `symmetric` is unspecified, `isSymmetric(x)` determines if the matrix is symmetric up to plausible numerical inaccuracies. It is surer and typically much faster to set the value yourself.

Computing the eigenvectors is the slow part for large matrices.

Computing the eigendecomposition of a matrix is subject to errors on a real-world computer: the definitive analysis is Wilkinson (1965). All you can hope for is a solution to a problem suitably close to `x`. So even though a real asymmetric `x` may have an algebraic solution with repeated real eigenvalues, the computed solution may be of a similar matrix with complex conjugate pairs of eigenvalues.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code (most often 1); these can only be interpreted by detailed study of the FORTRAN code.

Missing, NaN or infinite values in `x` will given an error.

Value

The spectral decomposition of `x` is returned as a list with components

<code>values</code>	a vector containing the p eigenvalues of <code>x</code> , sorted in <i>decreasing</i> order, according to <code>Mod(values)</code> in the asymmetric case when they might be complex (even for real matrices). For real asymmetric matrices the vector will be complex only if complex conjugate pairs of eigenvalues are detected.
<code>vectors</code>	either a $p \times p$ matrix whose columns contain the eigenvectors of <code>x</code> , or NULL if <code>only.values</code> is TRUE. The vectors are normalized to unit length. Recall that the eigenvectors are only defined up to a constant: even when the length is specified they are still only defined up to a scalar of modulus one (the sign for real matrices).

When `only.values` is not true, as by default, the result is of S3 class "eigen".

If `r <- eigen(A)`, and `V <- r$vectors`; `lam <- r$values`, then

$$A = V \Lambda V^{-1}$$

(up to numerical fuzz), where $\Lambda = \text{diag}(lam)$.

Source

`eigen` uses the LAPACK routines DSYEVR, DGEEV, ZHEEV and ZGEEV.

LAPACK is from <https://netlib.org/lapack/> and its guide is listed in the references.

eigen(cbind(c(1,-1), c(-1,1)), symmetric = FALSE)
# same (different algorithm).

eigen(cbind(1, c(1,-1)), only.values = TRUE)
eigen(cbind(-1, 2:1)) # complex values
eigen(print(cbind(c(0, 1i), c(-1i, 0)))) # Hermite ==> real Eigenvalues
## 3 x 3:
eigen(cbind( 1, 3:1, 1:3))
eigen(cbind(-1, c(1:2,0), 0:2)) # complex values
```

encodeString

Encode Character Vector as for Printing

Description

`encodeString` escapes the strings in a character vector in the same way `print.default` does, and optionally fits the encoded strings within a field width.

Usage

```
encodeString(x, width = 0, quote = "", na.encode = TRUE,
             justify = c("left", "right", "centre", "none"))
```

Arguments

<code>x</code>	a character vector, or an object that can be coerced to one by as.character .
<code>width</code>	integer: the minimum field width. If <code>NULL</code> or <code>NA</code> , this is taken to be the largest field width needed for any element of <code>x</code> .
<code>quote</code>	character: quoting character, if any.
<code>na.encode</code>	logical: should <code>NA</code> strings be encoded?

`justify` character: partial matches are allowed. If padding to the minimum field width is needed, how should spaces be inserted? `justify == "none"` is equivalent to `width = 0`, for consistency with `format.default`.

Details

This escapes backslash and the control characters `'\a'` (bell), `'\b'` (backspace), `'\f'` (form feed), `'\n'` (line feed, aka “newline”), `'\r'` (carriage return), `'\t'` (tab) and `'\v'` (vertical tab) as well as any non-printable characters in a single-byte locale, which are printed in octal notation (`'\xyz'` with leading zeroes).

Which characters are non-printable depends on the current locale. Windows’ reporting of printable characters is unreliable, so there all other control characters are regarded as non-printable, and all characters with codes 32–255 as printable in a single-byte locale. See `print.default` for how non-printable characters are handled in multi-byte locales.

If `quote` is a single or double quote any embedded quote of the same type is escaped. Note that justification is of the quoted string, hence spaces are added outside the quotes.

Value

A character vector of the same length as `x`, with the same attributes (including names and dimensions) but with no class set.

Marked UTF-8 encodings are preserved.

Note

The default for `width` is different from `format.default`, which does similar things for character vectors but without encoding using escapes.

See Also

`print.default`

Examples

```
x <- "ab\bc\ndef"
print(x)
cat(x) # interprets escapes
cat(encodeString(x), "\n", sep = "") # similar to print()

factor(x) # makes use of this to print the levels

x <- c("a", "ab", "abcde")
encodeString(x) # width = 0: use as little as possible
encodeString(x, 2) # use two or more (left justified)
encodeString(x, width = NA) # left justification
encodeString(x, width = NA, justify = "c")
encodeString(x, width = NA, justify = "r")
encodeString(x, width = NA, quote = "'", justify = "r")
```

Encoding*Read or Set the Declared Encodings for a Character Vector*

Description

Read or set the declared encodings for a character vector.

Usage

```
Encoding(x)
```

```
Encoding(x) <- value
```

```
enc2native(x)
```

```
enc2utf8(x)
```

Arguments

<code>x</code>	A character vector.
<code>value</code>	A character vector of positive length.

Details

Character strings in R can be declared to be encoded in "latin1" or "UTF-8" or as "bytes". These declarations can be read by `Encoding`, which will return a character vector of values "latin1", "UTF-8", "bytes" or "unknown", or set, when `value` is recycled as needed and other values are silently treated as "unknown". ASCII strings will never be marked with a declared encoding, since their representation is the same in all supported encodings. Strings marked as "bytes" are intended to be non-ASCII strings which should be manipulated as bytes, and never converted to a character encoding (so writing them to a text file is supported only by `writelnLines(useBytes = TRUE)`).

`enc2native` and `enc2utf8` convert elements of character vectors to the native encoding or UTF-8 respectively, taking any marked encoding into account. They are [primitive](#) functions, designed to do minimal copying.

There are other ways for character strings to acquire a declared encoding apart from explicitly setting it (and these have changed as R has evolved). The parser marks strings containing ‘\u’ or ‘\U’ escapes. Functions [scan](#), [read.table](#), [readLines](#), and [parse](#) have an `encoding` argument that is used to declare encodings, [iconv](#) declares encodings from its `to` argument, and console input in suitable locales is also declared. [intToUtf8](#) declares its output as "UTF-8", and output text connections (see [textConnection](#)) are marked if running in a suitable locale. Under some circumstances (see its help page) [source](#)(`encoding=`) will mark encodings of character strings it outputs.

Most character manipulation functions will set the encoding on output strings if it was declared on the corresponding input. These include [chartr](#), [strsplit](#)(`useBytes = FALSE`), [tolower](#) and [toupper](#) as well as [sub](#)(`useBytes = FALSE`) and [gsub](#)(`useBytes = FALSE`). Note that such functions do not *preserve* the encoding, but if they know the input encoding and that the string has been successfully re-encoded (to the current encoding or UTF-8), they mark the output.

[substr](#) does preserve the encoding, and [chartr](#), [tolower](#) and [toupper](#) preserve UTF-8 encoding on systems with Unicode wide characters. With their `fixed` and `perl` options, [strsplit](#), [sub](#) and [gsub](#) will give a marked UTF-8 result if any of the inputs are UTF-8.

`paste` and `sprintf` return elements marked as bytes if any of the corresponding inputs is marked as bytes, and otherwise marked as UTF-8 if any of the inputs is marked as UTF-8.

`match`, `pmatch`, `charmatch`, `duplicated` and `unique` all match in UTF-8 if any of the elements are marked as UTF-8.

Changing the current encoding from a running R session may lead to confusion (see `Sys.setlocale`).

There is some ambiguity as to what is meant by a ‘Latin-1’ locale, since some OSes (notably Windows) make use of character positions undefined (or used for control characters) in the ISO 8859-1 character set. How such characters are interpreted is system-dependent but as from R 3.5.0 they are if possible interpreted as per Windows codepage 1252 (which Microsoft calls ‘Windows Latin 1 (ANSI)’ when converting to e.g. UTF-8).

Value

A character vector.

For `enc2utf8` encodings are always marked: they are for `enc2native` in UTF-8 and Latin-1 locales.

Examples

```
## x is intended to be in latin1
x. <- x <- "fran\xE7ais"
Encoding(x.) # "unknown" (UTF-8 loc.) | "latin1" (8859-1/CP-1252 loc.) | ....
Encoding(x) <- "latin1"
x
xx <- iconv(x, "latin1", "UTF-8")
Encoding(c(x., x, xx))
c(x, xx)
xb <- xx; Encoding(xb) <- "bytes"
xb # will be encoded in hex
cat("x = ", x, ", xx = ", xx, ", xb = ", xb, "\n", sep = "")
(Ex <- Encoding(c(x., x, xx, xb)))
stopifnot(identical(Ex, c(Encoding(x.), Encoding(x),
                          Encoding(xx), Encoding(xb))))
```

environment

Environment Access

Description

Get, set, test for and create environments.

Usage

```
environment(fun = NULL)
environment(fun) <- value

is.environment(x)

.GlobalEnv
globalenv()
```

```

.BaseNamespaceEnv

emptyenv()
baseenv()

new.env(hash = TRUE, parent = parent.frame(), size = 29L)

parent.env(env)
parent.env(env) <- value

environmentName(env)

env.profile(env)

```

Arguments

<code>fun</code>	a function , a formula , or <code>NULL</code> , which is the default.
<code>value</code>	an environment to associate with the function.
<code>x</code>	an arbitrary R object.
<code>hash</code>	a logical, if <code>TRUE</code> the environment will use a hash table.
<code>parent</code>	an environment to be used as the enclosure of the environment created.
<code>env</code>	an environment.
<code>size</code>	an integer specifying the initial size for a hashed environment. An internal default value will be used if <code>size</code> is <code>NA</code> or zero. This argument is ignored if <code>hash</code> is <code>FALSE</code> .

Details

Environments consist of a *frame*, or collection of named objects, and a pointer to an *enclosing environment*. The most common example is the frame of variables local to a function call; its *enclosure* is the environment where the function was defined (unless changed subsequently). The enclosing environment is distinguished from the *parent frame*: the latter (returned by [parent.frame](#)) refers to the environment of the caller of a function. Since confusion is so easy, it is best never to use ‘parent’ in connection with an environment (despite the presence of the function `parent.env`).

When [get](#) or [exists](#) search an environment with the default `inherits = TRUE`, they look for the variable in the frame, then in the enclosing frame, and so on.

The global environment `.GlobalEnv`, more often known as the user’s workspace, is the first item on the search path. It can also be accessed by `globalenv()`. On the search path, each item’s enclosure is the next item.

The object `.BaseNamespaceEnv` is the namespace environment for the base package. The environment of the base package itself is available as `baseenv()`.

If one follows the chain of enclosures found by repeatedly calling `parent.env` from any environment, eventually one reaches the empty environment `emptyenv()`, into which nothing may be assigned.

The replacement function `parent.env<-` is extremely dangerous as it can be used to destructively change environments in ways that violate assumptions made by the internal C code. It may be removed in the near future.

The replacement form of `environment`, `is.environment`, `baseenv`, `emptyenv` and `globalenv` are [primitive](#) functions.

System environments, such as the base, global and empty environments, have names as do the package and namespace environments and those generated by `attach()`. Other environments can be named by giving a "name" attribute, but this needs to be done with care as environments have unusual copying semantics.

Value

If `fun` is a function or a formula then `environment(fun)` returns the environment associated with that function or formula. If `fun` is `NULL` then the current evaluation environment is returned.

The replacement form sets the environment of the function or formula `fun` to the `value` given. Note that `primitive` functions `fun` have no environment and trying to set it to a non-`NULL` value is deprecated.

`is.environment(obj)` returns `TRUE` if and only if `obj` is an environment.

`new.env` returns a new (empty) environment with (by default) enclosure the parent frame.

`parent.env` returns the enclosing environment of its argument.

`parent.env<-` sets the enclosing environment of its first argument.

`environmentName` returns a character string, that given when the environment is printed or "" if it is not a named environment.

`env.profile` returns a list with the following components: `size` the number of chains that can be stored in the hash table, `nchains` the number of non-empty chains in the table (as reported by `HASHPRI`), and `counts` an integer vector giving the length of each chain (zero for empty chains). This function is intended to assess the performance of hashed environments. When `env` is a non-hashed environment, `NULL` is returned.

See Also

For the performance implications of hashing or not, see https://en.wikipedia.org/wiki/Hash_table.

The `envir` argument of `eval`, `get`, and `exists`.

`ls` may be used to view the objects in an environment, and hence `ls.str` may be useful for an overview.

`sys.source` can be used to populate an environment.

Examples

```
f <- function() "top level function"

##-- all three give the same:
environment()
environment(f)
.GlobalEnv

ls(envir = environment(stats::approxfun(1:2, 1:2, method = "const")))

is.environment(.GlobalEnv) # TRUE

e1 <- new.env(parent = baseenv()) # this one has enclosure package:base.
e2 <- new.env(parent = e1)
assign("a", 3, envir = e1)
ls(e1)
ls(e2)
```

```
exists("a", envir = e2)    # this succeeds by inheritance
exists("a", envir = e2, inherits = FALSE)
exists("+", envir = e2)    # this succeeds by inheritance

eh <- new.env(hash = TRUE, size = NA)
with(env.profile(eh), stopifnot(size == length(counts)))
```

EnvVar

*Environment Variables***Description**

Details of some of the environment variables which affect an R session.

Details

It is impossible to list all the environment variables which can affect an R session: some affect the OS system functions which R uses, and others will affect add-on packages. But here are notes on some of the more important ones. Those that set the defaults for options are consulted only at startup (as are some of the others).

HOME: The user's 'home' directory.

LANGUAGE: Optional. The language(s) to be used for message translations. This is consulted when needed.

LC_ALL: (etc) Optional. Use to set various aspects of the locale – see [Sys.getlocale](#). Consulted at startup.

MAKEINDEX: The path to `makeindex`. If unset to a value determined when R was built. Used by the emulation mode of [texi2dvi](#) and [texi2pdf](#).

R_BATCH: Optional – set in a batch session, that is one started by R CMD [BATCH](#). Most often set to "", so test by something like `!is.na(Sys.getenv("R_BATCH", NA))`.

R_BROWSER: The path to the default browser. Used to set the default value of [options](#)("browser").

R_COMPLETION: Optional. If set to FALSE, command-line completion is not used. (Not used by the macOS GUI.)

R_DEFAULT_PACKAGES: A comma-separated list of packages which are to be attached in every session. See [options](#).

R_DOC_DIR: The location of the R 'doc' directory. Set by R.

R_ENVIRON: Optional. The path to the site environment file: see [Startup](#). Consulted at startup.

R_GSCMD: Optional. The path to Ghostscript, used by [dev2bitmap](#), [bitmap](#) and [embedFonts](#). Consulted when those functions are invoked. Since it will be treated as if passed to [system](#), spaces and shell metacharacters should be escaped.

R_HISTFILE: Optional. The path of the history file: see [Startup](#). Consulted at startup and when the history is saved.

R_HISTSIZE: Optional. The maximum size of the history file, in lines. Exactly how this is used depends on the interface.

On Unix-alikes, for the `readline` command-line interface it takes effect when the history is saved (by [savehistory](#) or at the end of a session).

On Windows, for `Rgui` it controls the number of lines saved to the history file: the size of the history used in the session is controlled by the console customization: see [Rconsole](#).

`R_HOME`: The top-level directory of the R installation: see [R.home](#). Set by R.

`R_INCLUDE_DIR`: The location of the R ‘include’ directory. Set by R.

`R_LIBS`: Optional. Used for initial setting of [.libPaths](#).

`R_LIBS_SITE`: Optional. Used for initial setting of [.libPaths](#).

`R_LIBS_USER`: Optional. Used for initial setting of [.libPaths](#).

`R_PAPERSIZE`: Optional. Used to set the default for [options](#) ("papersize"), e.g. used by [pdf](#) and [postscript](#).

`R_PCRE_JIT_STACK_MAXSIZE`: Optional. Consulted when PCRE’s JIT pattern compiler is first used. See [grep](#).

`R_PDFVIEWER`: The path to the default PDF viewer. Used by R CMD `Rd2pdf`.

`R_PLATFORM`: The platform – a string of the form "cpu-vendor-os", see [R.Version](#).

`R_PROFILE`: Optional. The path to the site profile file: see [Startup](#). Consulted at startup.

`R_RD4PDF`: Options for `pdflatex` processing of Rd files. Used by R CMD `Rd2pdf`.

`R_SHARE_DIR`: The location of the R ‘share’ directory. Set by R.

`R_TEXI2DVICMD`: The path to `texi2dvi`. Defaults to the value of `TEXI2DVI`, and if that is unset to a value determined when R was built.

Only on Unix-alikes:

Consulted at startup to set the default for [options](#) ("texi2dvi"), used by [texi2dvi](#) and [texi2pdf](#) in package **tools**.

`R_TIDYCMD`: The path to HTML tidy. Used by R CMD `check` if `_R_CHECK_RD_VALIDATE_RD2HTML_` is set to a true value (as it is by ‘--as-cran’).

`R_UNZIPCMD`: The path to `unzip`. Sets the initial value for [options](#) ("unzip") on a Unix-alike when namespace **utils** is loaded.

`R_ZIPCMD`: The path to `zip`. Used by [zip](#) and by R CMD `INSTALL --build` on Windows.

`TMPDIR`, `TMP`, `TEMP`: Consulted (in that order) when setting the temporary directory for the session: see [tempdir](#). `TMPDIR` is also used by some of the utilities: see the help for [build](#).

`TZ`: Optional. The current time zone. See [Sys.timezone](#) for the system-specific formats. Consulted as needed.

`TZDIR`: Optional. The top-level directory of the time-zone database. See [Sys.timezone](#).

`no_proxy`, `http_proxy`, `ftp_proxy`: (and more). Optional. Settings for [download.file](#): see its help for further details.

Unix-specific

Some variables set on Unix-alikes, and not (in general) on Windows.

`DISPLAY`: Optional: used by [X11](#), Tk (in package **tktk**), the data editor and various packages.

`EDITOR`: The path to the default editor: sets the default for [options](#) ("editor") when namespace **utils** is loaded.

`PAGER`: The path to the pager with the default setting of [options](#) ("pager"). The default value is chosen at configuration, usually as the path to `less`.

`R_PRINTCMD`: Sets the default for [options](#) ("printcmd"), which sets the default print command to be used by [postscript](#).

`R_SUPPORT_OLD_TARS` logical. Sets the default for the `support_old_tars` argument of [untar](#). Should be set to TRUE if an old system `tar` command is used which does not support either `xz` compression or automatically detecting compression type.

Windows-specific

Some Windows-specific variables are

GSC: Optional: the path to Ghostscript, used if `R_GSCMD` is not set.

R_USER: The user's 'home' directory. Set by `R`. (`HOME` will be set to the same value if not already set.)

See Also

[Sys.getenv](#) and [Sys.setenv](#) to read and set environmental variables in an `R` session.

[gctorture](#) for environment variables controlling garbage collection.

eval	<i>Evaluate an (Unevaluated) Expression</i>
------	---

Description

Evaluate an `R` expression in a specified environment.

Usage

```
eval(expr, envir = parent.frame(),
      enclos = if(is.list(envir) || is.pairlist(envir))
                 parent.frame() else baseenv())
evalq(expr, envir, enclos)
eval.parent(expr, n = 1)
local(expr, envir = new.env())
```

Arguments

<code>expr</code>	an object to be evaluated. See 'Details'.
<code>envir</code>	the environment in which <code>expr</code> is to be evaluated. May also be <code>NULL</code> , a list, a data frame, a pairlist or an integer as specified to sys.call .
<code>enclos</code>	relevant when <code>envir</code> is a (pair)list or a data frame. Specifies the enclosure, i.e., where <code>R</code> looks for objects not found in <code>envir</code> . This can be <code>NULL</code> (interpreted as the base package environment, baseenv()) or an environment.
<code>n</code>	number of parent generations to go back.

Details

`eval` evaluates the `expr` argument in the environment specified by `envir` and returns the computed value. If `envir` is not specified, then the default is [parent.frame\(\)](#) (the environment where the call to `eval` was made).

Objects to be evaluated can be of types [call](#) or [expression](#) or [name](#) (when the name is looked up in the current scope and its binding is evaluated), a [promise](#) or any of the basic types such as vectors, functions and environments (which are returned unchanged).

The `evalq` form is equivalent to `eval(quote(expr), ...)`. `eval` evaluates its first argument in the current scope before passing it to the evaluator: `evalq` avoids this.

`eval.parent(expr, n)` is a shorthand for `eval(expr, parent.frame(n))`.

If `envir` is a list (such as a data frame) or pairlist, it is copied into a temporary environment (with enclosure `enclos`), and the temporary environment is used for evaluation. So if `expr` changes any of the components named in the (pair)list, the changes are lost.

If `envir` is `NULL` it is interpreted as an empty list so no values could be found in `envir` and look-up goes directly to `enclos`.

`local` evaluates an expression in a local environment. It is equivalent to `evalq` except that its default argument creates a new, empty environment. This is useful to create anonymous recursive functions and as a kind of limited namespace feature since variables defined in the environment are not visible from the outside.

Value

The result of evaluating the object: for an expression vector this is the result of evaluating the last element.

Note

Due to the difference in scoping rules, there are some differences between R and S in this area. In particular, the default enclosure in S is the global environment.

When evaluating expressions in a data frame that has been passed as an argument to a function, the relevant enclosure is often the caller's environment, i.e., one needs `eval(x, data, parent.frame())`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X. (eval only.)

See Also

[expression](#), [quote](#), [sys.frame](#), [parent.frame](#), [environment](#).

Further, [force](#) to *force* evaluation, typically of function arguments.

Examples

```
eval(2 ^ 2 ^ 3)
mEx <- expression(2^2^3); mEx; 1 + eval(mEx)
eval({ xx <- pi; xx^2}) ; xx

a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, list(a = 1)), list(b = 5)) # == 10
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, -1), list(b = 5))          # == 12

ev <- function() {
  e1 <- parent.frame()
  ## Evaluate a in e1
  aa <- eval(expression(a), e1)
  ## evaluate the expression bound to a in e1
  a <- expression(x+y)
  list(aa = aa, eval = eval(a, e1))
}
tst.ev <- function(a = 7) { x <- pi; y <- 1; ev() }
tst.ev() #-> aa : 7, eval : 4.14

a <- list(a = 3, b = 4)
```

```

with(a, a <- 5) # alters the copy of a from the list, discarded.

##
## Example of evalq()
##

N <- 3
env <- new.env()
assign("N", 27, envir = env)
## this version changes the visible copy of N only, since the argument
## passed to eval is '4'.
eval(N <- 4, env)
N
get("N", envir = env)
## this version does the assignment in env, and changes N only there.
evalq(N <- 5, env)
N
get("N", envir = env)

##
## Uses of local()
##

# Mutually recursive.
# gg gets value of last assignment, an anonymous version of f.

gg <- local({
  k <- function(y) f(y)
  f <- function(x) if(x) x*k(x-1) else 1
})
gg(10)
sapply(1:5, gg)

# Nesting locals: a is private storage accessible to k
gg <- local({
  k <- local({
    a <- 1
    function(y) {print(a <- a+1); f(y)}
  })
  f <- function(x) if(x) x*k(x-1) else 1
})
sapply(1:5, gg)

ls(envir = environment(gg))
ls(envir = environment(get("k", envir = environment(gg))))

```

exists

Is an Object Defined?

Description

Look for an R object of the given name and possibly return it

Usage

```
exists(x, where = -1, envir = , frame, mode = "any",
       inherits = TRUE)

get0(x, envir = pos.to.env(-1L), mode = "any", inherits = TRUE,
     ifnotfound = NULL)
```

Arguments

<code>x</code>	a variable name (given as a character string or a symbol).
<code>where</code>	where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
<code>envir</code>	an alternative way to specify an environment to look in, but it is usually simpler to just use the <code>where</code> argument.
<code>frame</code>	a frame in the calling list. Equivalent to giving <code>where</code> as <code>sys.frame(frame)</code> .
<code>mode</code>	the mode or type of object sought: see the ‘Details’ section.
<code>inherits</code>	should the enclosing frames of the environment be searched?
<code>ifnotfound</code>	the return value of <code>get0(x, *)</code> when <code>x</code> does not exist.

Details

The `where` argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name `x` has a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See [environment](#) and *The R Language Definition* for details about the structure of environments and their enclosures.

Warning: `inherits = TRUE` is the default behaviour for R but not for S.

If `mode` is specified then only objects of that type are sought. The `mode` may specify one of the collections "numeric" and "function" (see [mode](#)): any member of the collection will suffice. (This is true even if a member of a collection is specified, so for example `mode = "special"` will seek any type of function.)

Value

`exists()` : Logical, true if and only if an object of the correct name and mode is found.

`get0()` : The object—as from [get](#)(`x, *`)— if `exists(x, *)` is true, otherwise `ifnotfound`.

Note

With `get0()`, instead of the easy to read but somewhat inefficient

```
if (exists(myVarName, envir = myEnvir)) {
  r <- get(myVarName, envir = myEnvir)
  ## ... deal with r ...
```

```
}
```

you now can use the more efficient (and slightly harder to read)

```
if (!is.null(r <- get0(myVarName, envir = myEnvir))) {
  ## ... deal with r ...
}
```

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`get` and `hasName`. For quite a different kind of “existence” checking, namely if function arguments were specified, `missing`; and for yet a different kind, namely if a file exists, `file.exists`.

Examples

```
## Define a substitute function if necessary:
if(!exists("some.fun", mode = "function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos = 3
exists("ls", 2, inherits = FALSE) # false

## These are true (in most circumstances):
identical(ls, get0("ls"))
identical(NULL, get0(".foo.bar.")) # default ifnotfound = NULL (!)
```

expand.grid

Create a Data Frame from All Combinations of Factor Variables

Description

Create a data frame from all combinations of the supplied vectors or factors. See the description of the return value for precise details of the way this is done.

Usage

```
expand.grid(..., KEEP.OUT.ATTRS = TRUE, stringsAsFactors = TRUE)
```

Arguments

`...` vectors, factors or a list containing these.

`KEEP.OUT.ATTRS` a logical indicating the "out.attrs" attribute (see below) should be computed and returned.

`stringsAsFactors` logical specifying if character vectors are converted to factors.

Value

A data frame containing one row for each combination of the supplied factors. The first factors vary fastest. The columns are labelled by the factors if these are supplied as named arguments or named components of a list. The row names are 'automatic'.

Attribute "out.attrs" is a list which gives the dimension and dimnames for use by `predict` methods.

Note

Conversion to a factor is done with levels in the order they occur in the character vectors (and not alphabetically, as is most common when converting to factors).

References

Chambers JM, Hastie TJ (1992). *Statistical Models in S*. Chapman & Hall, London. ISBN 9780412830402.

See Also

`combn`(*n*, *m*) for the generation of all combinations of *n* elements, taken *m* at a time.

Examples

```
require(utils)

expand.grid(height = seq(60, 80, 5), weight = seq(100, 300, 50),
            sex = c("Male", "Female"))

x <- seq(0, 10, length.out = 100)
y <- seq(-1, 1, length.out = 20)
d1 <- expand.grid(x = x, y = y)
d2 <- expand.grid(x = x, y = y, KEEP.OUT.ATTRS = FALSE)
object.size(d1) - object.size(d2)
##-> 5992 or 8832 (on 32- / 64-bit platform)
```

expression

Unevaluated Expressions

Description

Creates or tests for objects of mode and class "expression".

Usage

```
expression(...)

is.expression(x)
as.expression(x, ...)
```

Arguments

... expression: R objects, typically calls, symbols or constants.
 as.expression: arguments to be passed to methods.

x an arbitrary R object.

Details

'Expression' here is not being used in its colloquial sense, that of mathematical expressions. Those are calls (see [call](#)) in R, and an R expression vector is a list of calls, symbols etc, for example as returned by [parse](#).

As an object of mode "expression" is a list, it can be subsetted by [, [[or \$, the latter two extracting individual calls etc. The replacement forms of these operators can be used to replace or delete elements.

expression and is.expression are [primitive](#) functions. expression is 'special': it does not evaluate its arguments.

Value

expression returns a vector of type "expression" containing its arguments (unevaluated).

is.expression returns TRUE if expr is an expression object and FALSE otherwise.

as.expression attempts to coerce its argument into an expression object. It is generic, and only the default method is described here. (The default method calls `as.vector(type = "expression")` and so may dispatch methods for [as.vector](#).) NULL, calls, symbols (see [as.symbol](#)) and pairlists are returned as the element of a length-one expression vector. Atomic vectors are placed element-by-element into an expression vector (without using any names): [lists](#) have their type ([typeof](#)) changed to an expression vector (keeping all attributes). Other types are not currently supported.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[call](#), [eval](#), [function](#). Further, [text](#), [legend](#), and [plotmath](#) for plotting mathematical expressions.

Examples

```
length(ex1 <- expression(1 + 0:9)) # 1
ex1
eval(ex1) # 1:10

length(ex3 <- expression(u, 2, u + 0:9)) # 3
mode(ex3 [3]) # expression
mode(ex3[[3]]) # call
## but not all components are 'call's :
sapply(ex3, mode) # name numeric call
sapply(ex3, typeof) # symbol double language
rm(ex3)
```

Description

Operators acting on vectors, matrices, arrays and lists to extract or replace parts.

Usage

```
x[i]
x[i, j, ... , drop = TRUE]
x[[i, exact = TRUE]]
x[[i, j, ..., exact = TRUE]]
x$name
getElement(object, name)

x[i] <- value
x[i, j, ...] <- value
x[[i]] <- value
x$name <- value
```

Arguments

<code>x, object</code>	object from which to extract element(s) or in which to replace element(s).
<code>i, j, ...</code>	indices specifying elements to extract or replace. Indices are numeric or character vectors or empty (missing) or <code>NULL</code>. Numeric values are coerced to integer or whole numbers as by <code>as.integer</code> or for large values by <code>trunc</code> (and hence truncated towards zero). Character vectors will be matched to the <code>names</code> of the object (or for matrices/arrays, the <code>dimnames</code>): see ‘Character indices’ below for further details. For <code>[]</code>-indexing only: <code>i, j, ...</code> can be logical vectors, indicating elements/slices to select. Such vectors are recycled if necessary to match the corresponding extent. <code>i, j, ...</code> can also be negative integers, indicating elements/slices to leave out of the selection. When indexing arrays by <code>[]</code> a single argument <code>i</code> can be a matrix with as many columns as there are dimensions of <code>x</code>; the result is then a vector with elements corresponding to the sets of indices in each row of <code>i</code>. An index value of <code>NULL</code> is treated as if it were <code>integer(0)</code>.
<code>name</code>	a literal character string or a <code>name</code> (possibly <code>backtick</code> quoted). For extraction, this is normally (see under ‘Environments’) partially matched to the <code>names</code> of the object.
<code>drop</code>	relevant for matrices and arrays. If <code>TRUE</code> the result is coerced to the lowest possible dimension (see the examples). This only works for extracting elements, not for the replacement. See <code>drop</code> for further details.
<code>exact</code>	controls possible partial matching of <code>[]</code> when extracting by a character vector (for most objects, but see under ‘Environments’). The default is no partial matching. Value <code>NA</code> allows partial matching but issues a warning when it occurs. Value <code>FALSE</code> allows partial matching without any warning.
<code>value</code>	typically an array-like R object of a similar class as <code>x</code> .

Details

These operators are generic. You can write methods to handle indexing of specific classes of objects, see [InternalMethods](#) as well as `[.data.frame]` and `[.factor]`. The descriptions here apply only to the default methods. Note that separate methods are required for the replacement functions `[<-`, `[ [<-` and `$<-` for use when indexing occurs on the assignment side of an expression.

The most important distinction between `[`, `[ [` and `$` is that the `[` can select more than one element whereas the other two select a single element.

Note that `x [ [ ] ]` is always erroneous.

The default methods work somewhat differently for atomic vectors, matrices/arrays and for recursive (list-like, see `is.recursive`) objects. `$` is only valid for recursive objects (and `NULL`), and is only discussed in the section below on recursive objects.

Subsetting (except by an empty index) will drop all attributes except `names`, `dim` and `dimnames`.

Indexing can occur on the right-hand-side of an expression for extraction, or on the left-hand-side for replacement. When an index expression appears on the left side of an assignment (known as *subassignment*) then that part of `x` is set to the value of the right hand side of the assignment. In this case no partial matching of character indices is done, and the left-hand-side is coerced as needed to accept the values. For vectors, the answer will be of the higher of the types of `x` and `value` in the hierarchy `raw < logical < integer < double < complex < character < list < expression`. Attributes are preserved (although `names`, `dim` and `dimnames` will be adjusted suitably). Subassignment is done sequentially, so if an index is specified more than once the latest assigned value for an index will result.

It is an error to apply any of these operators to an object which is not subsettable (e.g., a function).

Atomic vectors

The usual form of indexing is `[`. `[ [` can be used to select a single element *dropping* `names`, whereas `[` keeps them, e.g., in `c(abc = 123) [1]`.

The index object `i` can be numeric, logical, character or empty. Indexing by factors is allowed and is equivalent to indexing by the numeric codes (see `factor`) and not by the character values which are printed (for which use `[as.character(i)]`).

An empty index selects all values: this is most often used to replace all the entries but keep the `attributes`.

Matrices and arrays

Matrices and arrays are vectors with a dimension attribute and so all the vector forms of indexing can be used with a single index. The result will be an unnamed vector unless `x` is one-dimensional when it will be a one-dimensional array.

The most common form of indexing a k -dimensional array is to specify k indices to `[`. As for vector indexing, the indices can be numeric, logical, character, empty or even factor. And again, indexing by factors is equivalent to indexing by the numeric codes, see ‘Atomic vectors’ above.

An empty index (a comma separated blank) indicates that all entries in that dimension are selected. The argument `drop` applies to this form of indexing.

A third form of indexing is via a numeric matrix with the one column for each dimension: each row of the index matrix then selects a single element of the array, and the result is a vector. Negative indices are not allowed in the index matrix. `NA` and zero values are allowed: rows of an index matrix containing a zero are ignored, whereas rows containing an `NA` produce an `NA` in the result.

Indexing via a character matrix with one column per dimensions is also supported if the array has dimension names. As with numeric matrix indexing, each row of the index matrix selects a single

element of the array. Indices are matched against the appropriate dimension names. NA is allowed and will produce an NA in the result. Unmatched indices as well as the empty string ("") are not allowed and will result in an error.

A vector obtained by matrix indexing will be unnamed unless *x* is one-dimensional when the row names (if any) will be indexed to provide names for the result.

Recursive (list-like) objects

Indexing by `[]` is similar to atomic vectors and selects a list of the specified element(s).

Both `[]` and `$` select a single element of the list. The main difference is that `$` does not allow computed indices, whereas `[]` does. `x$name` is equivalent to `x[["name", exact = FALSE]]`. Also, the partial matching behavior of `[]` can be controlled using the `exact` argument.

`getElement(x, name)` is a version of `x[[name, exact = TRUE]]` which for formally classed (S4) objects returns `slot(x, name)`, hence providing access to even more general list-like objects.

`[]` and `[]` are sometimes applied to other recursive objects such as [calls](#) and [expressions](#). Pairlists (such as calls) are coerced to lists for extraction by `[]`, but all three operators can be used for replacement.

`[]` can be applied recursively to lists, so that if the single index *i* is a vector of length *p*, `alist[[i]]` is equivalent to `alist[[i1]]...[[ip]]` providing all but the final indexing results in a list.

Attempts to extract a non-existent element by name return `NULL`.

Note that in all three kinds of replacement, a value of `NULL` deletes the corresponding item of the list. To set entries to `NULL`, you need `x[i] <- list(NULL)`.

When `$<-` is applied to a `NULL` *x*, it first coerces *x* to `list()`. This is what also happens with `[]<-` where in R versions before 4.0.0, a length one value resulted in a length one (atomic) *vector*.

Environments

Both `$` and `[]` can be applied to environments. Only character indices are allowed and no partial matching is done. The semantics of these operations are those of `get(i, env = x, inherits = FALSE)`. If no match is found then `NULL` is returned. The replacement versions, `$<-` and `[]<-`, can also be used. Again, only character arguments are allowed. The semantics in this case are those of `assign(i, value, env = x, inherits = FALSE)`. Such an assignment will either create a new binding or change the existing binding in *x*.

NAs in indexing

When extracting, a numerical, logical or character NA index picks an unknown element and so returns NA in the corresponding element of a logical, integer, numeric, complex or character result, and `NULL` for a list. (It returns `00` for a raw result.)

When replacing (that is using indexing on the lhs of an assignment) NA does not select any element to be replaced. As there is ambiguity as to whether an element of the rhs should be used or not, this is only allowed if the rhs value is of length one (so the two interpretations would have the same outcome). (The documented behaviour of S was that an NA replacement index ‘goes nowhere’ but uses up an element of `value`: Becker, Chambers, and Wilks (1988, page 359). However, that has not been true of other implementations.)

Argument matching

Note that these operations do not match their index arguments in the standard way: argument names are ignored and positional matching only is used. So `m[j = 2, i = 1]` is equivalent to `m[2, 1]` and **not** to `m[1, 2]`.

This may not be true for methods defined for them; for example it is not true for the `data.frame` methods described in `[.data.frame]` which warn if `i` or `j` is named and have undocumented behaviour in that case.

To avoid confusion, do not name index arguments (but `drop` and `exact` must be named).

S4 methods

These operators are also implicit S4 generics, but as primitives, S4 methods will be dispatched only on S4 objects `x`.

The implicit generics for the `$` and `$<-` operators do not have `name` in their signature because the grammar only allows symbols or string constants for the `name` argument.

Character indices

Character indices can in some circumstances be partially matched (see `pmatch`) to the names or dimnames of the object being subsetting (but never for subassignment). Unlike S (Becker et al. 1988, page 358), R never uses partial matching when extracting by `[`, and partial matching is not by default used by `[[` (see argument `exact`).

Thus the default behaviour is to use partial matching only when extracting from recursive objects (except environments) by `$`. Even in that case, warnings can be switched on by `options(warnPartialMatchDollar = TRUE)`.

Neither empty (`" "`) nor NA indices match any names, not even empty nor missing names. If any object has no names or appropriate dimnames, they are taken as all `" "` and so match nothing.

Error conditions

Attempting to apply a subsetting operation to objects for which this is not possible signals an error of class `notSubsettableError`. The `object` component of the error condition contains the non-subsettable object.

Subscript out of bounds errors are signaled as errors of class `subscriptOutOfBoundsError`. The `object` component of the error condition contains the object being subsetting. The integer `subscript` component is zero for vector subscripting, and for multiple subscripts indicates which subscript was out of bounds. The `index` component contains the erroneous index.

Examples

```

x <- 1:12
m <- matrix(1:6, nrow = 2, dimnames = list(c("a", "b"), LETTERS[1:3]))
li <- list(pi = pi, e = exp(1))
x[10]                # the tenth element of x
x <- x[-1]            # delete the 1st element of x
m[1,]                # the first row of matrix m
m[1, , drop = FALSE] # is a 1-row matrix
m[,c(TRUE,FALSE,TRUE)]# logical indexing
m[cbind(c(1,2,1),3:1)]# matrix numeric index
ci <- cbind(c("a", "b", "a"), c("A", "C", "B"))
m[ci]                # matrix character index
m <- m[,-1]           # delete the first column of m
li[[1]]              # the first element of list li
y <- list(1, 2, a = 4, 5)
y[c(3, 4)]           # a list containing elements 3 and 4 of y
y$a                  # the element of y named a

## non-integer indices are truncated:
(i <- 3.999999999) # "4" is printed
(1:5)[i]          # 3

## named atomic vectors, compare "[" and "[[" :
nx <- c(ABC = 123, pi = pi)
nx[1] ; nx["pi"] # keeps names, whereas "[" does not:
nx[[1]] ; nx[["pi"]]

## recursive indexing into lists
z <- list(a = list(b = 9, c = "hello"), d = 1:5)
unlist(z)
z[[c(1, 2)]]
z[[c(1, 2, 1)]] # both "hello"
z[[c("a", "b")]] <- "new"
unlist(z)

## check $ and [[ for environments
e1 <- new.env()
e1$a <- 10
e1[["a"]]
e1[["b"]] <- 20
e1$b
ls(e1)

## partial matching - possibly with warning :
stopifnot(identical(li$p, pi))
op <- options(warnPartialMatchDollar = TRUE)
stopifnot( identical(li$p, pi), #-- a warning
  inherits(tryCatch(li$p, warning = identity), "warning"))
## revert the warning option:
options(op)

```

Description

Extract or replace subsets of data frames.

Usage

```
## S3 method for class 'data.frame'
x[i, j, drop = ]
## S3 replacement method for class 'data.frame'
x[i, j] <- value
## S3 method for class 'data.frame'
x[..., exact = TRUE]]
## S3 replacement method for class 'data.frame'
x[[i, j]] <- value
## S3 replacement method for class 'data.frame'
x$name <- value
```

Arguments

<code>x</code>	data frame.
<code>i, j, ...</code>	elements to extract or replace. For <code>[</code> and <code>[[</code> , these are numeric or character or, for <code>[</code> only, empty or logical. Numeric values are coerced to integer as if by <code>as.integer</code> . For replacement by <code>[</code> , a logical matrix is allowed.
<code>name</code>	a literal character string or a name (possibly backtick quoted).
<code>drop</code>	logical. If <code>TRUE</code> the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but not to drop if only one row is left.
<code>value</code>	a suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If <code>NULL</code> , deletes the column if a single column is selected.
<code>exact</code>	logical: see <code>[</code> , and applies to column names.

Details

Data frames can be indexed in several modes. When `[` and `[[` are used with a single vector index (`x[i]` or `x[[i]]`), they index the data frame as if it were a list. In this usage a `drop` argument is ignored, with a warning.

There is no `data.frame` method for `$`, so `x$name` uses the default method which treats `x` as a list (with partial matching of column names if the match is unique, see [Extract](#)). The replacement method (for `$`) checks `value` for the correct number of rows, and replicates it if necessary.

When `[` and `[[` are used with two indices (`x[i, j]` and `x[[i, j]]`) they act like indexing a matrix: `[[` can only be used to select one element. Note that for each selected column, `xj` say, typically (if it is not matrix-like), the resulting column will be `xj[i]`, and hence rely on the corresponding `[` method, see the examples section.

If `[` returns a data frame it will have unique (and non-missing) row names, if necessary transforming the row names using [make.unique](#). Similarly, if columns are selected column names will be transformed to be unique if necessary (e.g., if columns are selected more than once, or if more than one column of a given name is selected if the data frame has duplicate column names).

When `drop = TRUE`, this is applied to the subsetting of any matrices contained in the data frame as well as to the data frame itself.

The replacement methods can be used to add whole column(s) by specifying non-existent column(s), in which case the column(s) are added at the right-hand edge of the data frame and numerical indices must be contiguous to existing indices. On the other hand, rows can be added at any row after the current last row, and the columns will be in-filled with missing values. Missing values in the indices are not allowed for replacement.

For `[` the replacement value can be a list: each element of the list is used to replace (part of) one column, recycling the list as necessary. If columns specified by number are created, the names (if any) of the corresponding list elements are used to name the columns. If the replacement is not selecting rows, list values can contain `NULL` elements which will cause the corresponding columns to be deleted. (See the Examples.)

Matrix indexing (`x[i]` with a logical or a 2-column integer matrix `i`) using `[` is not recommended. For extraction, `x` is first coerced to a matrix. For replacement, logical matrix indices must be of the same dimension as `x`. Replacements are done one column at a time, with multiple type coercions possibly taking place.

Both `[` and `[[` extraction methods partially match row names. By default neither partially match column names, but `[[` will if `exact = FALSE` (and with a warning if `exact = NA`). If you want to exact matching on row names use `match`, as in the examples.

Value

For `[` a data frame, list or a single column (the latter two only when dimensions have been dropped). If matrix indexing is used for extraction a vector results. If the result would be a data frame an error results if undefined columns are selected (as there is no general concept of a 'missing' column in a data frame). Otherwise if a single column is selected and this is undefined the result is `NULL`.

For `[[` a column of the data frame or `NULL` (extraction with one index) or a length-one vector (extraction with two indices).

For `$`, a column of the data frame (or `NULL`).

For `[<-`, `[[<-` and `$<-`, a data frame.

Coercion

The story over when replacement values are coerced is a complicated one, and one that has changed during R's development. This section is a guide only.

When `[` and `[[` are used to add or replace a whole column, no coercion takes place but `value` will be replicated (by calling the generic function `rep`) to the right length if an exact number of repeats can be used.

When `[` is used with a logical matrix, each value is coerced to the type of the column into which it is to be placed.

When `[` and `[[` are used with two indices, the column will be coerced as necessary to accommodate the value.

Note that when the replacement value is an array (including a matrix) it is *not* treated as a series of columns (as `data.frame` and `as.data.frame` do) but inserted as a single column.

Warning

The default behaviour when only one *row* is left is equivalent to specifying `drop = FALSE`. To drop from a data frame to a list, `drop = TRUE` has to be specified explicitly.

Arguments other than `drop` and `exact` should not be named: there is a warning if they are and the behaviour differs from the description here.

See Also

`subset` which is often easier for extraction, `data.frame`, `Extract`.

Examples

```
sw <- swiss[1:5, 1:4] # select a manageable subset

sw[1:3]      # select columns
sw[, 1:3]    # same
sw[4:5, 1:3] # select rows and columns
sw[1]        # a one-column data frame
sw[, 1, drop = FALSE] # the same
sw[, 1]      # a (unnamed) vector
sw[[1]]      # the same
sw$Fert      # the same (possibly w/ warning, see ?Extract)

sw[1,]       # a one-row data frame
sw[1,, drop = TRUE] # a list

sw["C", ] # partially matches
sw[match("C", row.names(sw)), ] # no exact match
try(sw[, "Ferti"]) # column names must match exactly

sw[sw$Fertility > 90,] # logical indexing, see also ?subset
sw[c(1, 1:2), ]      # duplicate row, unique row names are created

sw[sw <= 6] <- 6 # logical matrix indexing
sw

## adding a column
sw["new1"] <- LETTERS[1:5] # adds a character column
sw[["new2"]] <- letters[1:5] # ditto
sw[, "new3"] <- LETTERS[1:5] # ditto
sw$new4 <- 1:5
sapply(sw, class)
sw$new # -> NULL: no unique partial match
sw$new4 <- NULL # delete the column
sw
sw[6:8] <- list(letters[10:14], NULL, aa = 1:5)
# update col. 6, delete 7, append
sw

## matrices in a data frame
A <- data.frame(x = 1:3, y = I(matrix(4:9, 3, 2)),
               z = I(matrix(letters[1:9], 3, 3)))
A[1:3, "y"] # a matrix
A[1:3, "z"] # a matrix
A[, "y"]    # a matrix
stopifnot(identical(colnames(A), c("x", "y", "z")), ncol(A) == 3L,
           identical(A[, "y"], A[1:3, "y"]),
           inherits(A[, "y"], "AsIs"))

## keeping special attributes: use a class with a
## "as.data.frame" and "[" method;
## "avector" := vector that keeps attributes. Could provide a constructor
```

```
## avector <- function(x) { class(x) <- c("avector", class(x)); x }
as.data.frame.avector <- as.data.frame.vector

`[,.avector` <- function(x,i,...) {
  r <- NextMethod("[")
  mostattributes(r) <- attributes(x)
  r
}

d <- data.frame(i = 0:7, f = gl(2,4),
               u = structure(11:18, unit = "kg", class = "avector"))
str(d[2:4, -1]) # 'u' keeps its "unit"
```

Extract.factor

Extract or Replace Parts of a Factor

Description

Extract or replace subsets of factors.

Usage

```
## S3 method for class 'factor'
x[... , drop = FALSE]
## S3 method for class 'factor'
x[[...]]
## S3 replacement method for class 'factor'
x[...] <- value
## S3 replacement method for class 'factor'
x[[...]] <- value
```

Arguments

<code>x</code>	a factor.
<code>...</code>	a specification of indices – see Extract .
<code>drop</code>	logical. If true, unused levels are dropped.
<code>value</code>	character: a set of levels. Factor values are coerced to character.

Details

When unused levels are dropped the ordering of the remaining levels is preserved.

If `value` is not in `levels(x)`, a missing value is assigned with a warning.

Any [contrasts](#) assigned to the factor are preserved unless `drop = TRUE`.

The `[ [` method supports argument `exact`.

Value

A factor with the same set of levels as `x` unless `drop = TRUE`.

See Also

[factor](#), [Extract](#).

Examples

```
## following example(factor)
(ff <- factor(substring("statistics", 1:10, 1:10), levels = letters))
ff[, drop = TRUE]
factor(letters[7:10])[2:3, drop = TRUE]
```

Extremes

Maxima and Minima

Description

Returns the (regular or **parallel**) maxima and minima of the input values.

`pmax*`() and `pmin*`() take one or more vectors as arguments, recycle them to common length and return a single vector giving the ‘*parallel*’ maxima (or minima) of the argument vectors.

Usage

```
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)

pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)

pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

Arguments

<code>...</code>	numeric or character arguments (see Note).
<code>na.rm</code>	a logical (TRUE or FALSE) indicating whether missing values should be removed.

Details

`max` and `min` return the maximum or minimum of *all* the values present in their arguments, as [integer](#) if all are logical or integer, as [double](#) if all are numeric, and character otherwise.

If `na.rm` is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are `+Inf` and `-Inf` (in this order!) which ensures *transitivity*, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x` `max(x) == -Inf` and `min(x) == +Inf` whenever `length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the ‘parallel’ maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is

the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs (of non-zero length) are recycled if necessary. Attributes (see [attributes](#): such as [names](#) or [dim](#)) are copied from the first argument (if applicable, e.g., *not* for an S4 object).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordering.)

`max` and `min` are generic functions: methods can be defined for them individually or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

By definition the min/max of a numeric vector containing an NaN is NaN, except that the min/max of any vector containing an NA is NA even if it also contains an NaN. Note that `max(NA, Inf) == NA` even though the maximum would be `Inf` whatever the missing value actually is.

Character versions are sorted lexicographically, and this depends on the collating sequence of the locale in use: the help for [‘Comparison’](#) gives details. The max/min of an empty character vector is defined to be character NA. (One could argue that as `" "` is the smallest character element, the maximum should be `" "`, but there is no obvious candidate for the minimum.)

Value

For `min` or `max`, a length-one vector. For `pmin` or `pmax`, a vector of length the longest of the input vectors, or length zero if one of the inputs had zero length.

The type of the result will be that of the highest of the inputs in the hierarchy integer < double < character.

For `min` and `max` if there are only numeric inputs and all are empty (after possible removal of NAs), the result is double (`Inf` or `-Inf`).

S4 methods

`max` and `min` are part of the S4 [Summary](#) group generic. Methods for them must use the signature `x, ..., na.rm`.

Note

‘Numeric’ arguments are vectors of type integer and numeric, and logical (coerced to integer). For historical reasons, NULL is accepted as equivalent to `integer(0)`.

`pmax` and `pmin` will also work on classed S3 or S4 objects with appropriate methods for comparison, `is.na` and `rep` (if recycling of arguments is needed).

See Also

[range](#) (both min and max) and [which.min](#) ([which.max](#)) for the *arg min*, i.e., the location where an extreme value occurs.

[‘plotmath’](#) for the use of `min` in plot annotation.

Examples

```
require(stats); require(graphics)
min(5:1, pi) #-> one number
pmin(5:1, pi) #-> 5 numbers

x <- sort(rnorm(100)); cH <- 1.35
pmin(cH, quantile(x)) # no names
pmin(quantile(x), cH) # has names
plot(x, pmin(cH, pmax(-cH, x)), type = "b", main = "Huber's function")

cut01 <- function(x) pmax(pmin(x, 1), 0)
curve(x^2 - 1/4, -1.4, 1.5, col = 2)
curve(cut01(x^2 - 1/4), col = "blue", add = TRUE, n = 500)
## pmax(), pmin() preserve attributes of *first* argument
D <- diag(x = (3:1)/4) ; n0 <- numeric()
stopifnot(identical(D, cut01(D)),
           identical(n0, cut01(n0)),
           identical(n0, cut01(NULL)),
           identical(n0, pmax(3:1, n0, 2)),
           identical(n0, pmax(n0, 4)))
```

extSoftVersion

Report Versions of Third-Party Software

Description

Report versions of (external) third-party software used.

Usage

```
extSoftVersion()
```

Details

The reports the versions of third-party software libraries in use. These are often external but might have been compiled into R when it was installed.

With dynamic linking, these are the versions of the libraries linked to in this session: with static linking, of those compiled in.

Value

A named character vector, currently with components

zlib	The version of zlib in use.
bzlib	The version of bzlib (from bzip2) in use.
xz	The version of liblzma (from xz) in use.
libdeflate	The version of libdeflate (if any, otherwise "") used when R was built.
zstd	The version of libzstd (from zstd) in use (if any, otherwise "").
PCRE	The version of PCRE in use. PCRE1 has versions < 10.00, PCRE2 has versions >= 10.00.
ICU	The version of ICU in use (if any, otherwise "").

TRE	The version of <code>libtre</code> in use.
iconv	The implementation and version of the <code>iconv</code> library in use (if known).
readline	The version of <code>readline</code> in use (if any, otherwise <code>" "</code>). If using the emulation by <code>libedit</code> aka <code>editline</code> this will be <code>"EditLine wrapper"</code> preceded by the <code>readline</code> version it emulates: that is most likely to be seen on macOS.
BLAS	Name of the binary/executable file with the implementation of BLAS in use (if known, otherwise <code>" "</code>).

Note that the values for `bzlib` and `pcre` normally contain a date as well as the version number, and that for `tre` includes several items separated by spaces, the version number being the second.

For `iconv` this will give the implementation as well as the version, for example `"GNU libiconv 1.14"`, `"glibc 2.18"` or `"win_iconv"` (which has no version number).

The name of the binary/executable file for BLAS can be used as an indication of which implementation is in use. Typically, the R version of BLAS will appear as `libR.so` (`libR.dylib`), `R` or `libRblas.so` (`libRblas.dylib`), depending on how R was built. Note that `libRblas.so` (`libRblas.dylib`) may also be shown for an external BLAS implementation that had been copied, hard-linked or renamed by the system administrator. For an external BLAS, a shared object file will be given and its path/name may indicate the vendor/version. The detection does not work on Windows nor for some uses of the Accelerate framework on macOS.

See Also

`libcurlVersion` for the version of `libCurl`.

`La_version` for the version of LAPACK in use.

`La_library` for binary/executable file with LAPACK in use.

`grSoftVersion` for third-party graphics software.

`tclVersion` in package `tcltk` for the version of Tcl/Tk.

`pcre_config` for PCRE configuration options.

`connection` for how to use the file and connection compression methods `"zlib"`, `"bzlib"`, `"xz"`, `"libdeflate"`, and `"zstd"`.

Examples

```
extSoftVersion()
## the PCRE version
sub(".*", "", extSoftVersion()["PCRE"])
```

factor

Factors

Description

The function `factor` is used to encode a vector as a factor (the terms ‘category’ and ‘enumerated type’ are also used for factors). If argument `ordered` is `TRUE`, the factor levels are assumed to be ordered. For compatibility with S there is also a function `ordered`.

`is.factor`, `is.ordered`, `as.factor` and `as.ordered` are the membership and coercion functions for these classes.

Usage

```
factor(x = character(), levels, labels = levels,
       exclude = NA, ordered = is.ordered(x), nmax = NA)

ordered(x = character(), ...)

is.factor(x)
is.ordered(x)

as.factor(x)
as.ordered(x)

addNA(x, ifany = FALSE)

.valid.factor(object)
```

Arguments

<code>x</code>	a vector of data, usually taking a small number of distinct values.
<code>levels</code>	an optional vector of the unique values (as character strings) that <code>x</code> might have taken. The default is the unique set of values taken by <code>as.character(x)</code> , sorted into increasing order of <code>x</code> . Note that this set can be specified as smaller than <code>sort(unique(x))</code> .
<code>labels</code>	<i>either</i> an optional character vector of labels for the levels (in the same order as <code>levels</code> after removing those in <code>exclude</code>), <i>or</i> a character string of length 1. Duplicated values in <code>labels</code> can be used to map different values of <code>x</code> to the same factor level.
<code>exclude</code>	a vector of values to be excluded when forming the set of levels. This may be factor with the same level set as <code>x</code> or should be a character.
<code>ordered</code>	logical flag to determine if the levels should be regarded as ordered (in the order given).
<code>nmax</code>	an upper bound on the number of levels; see ‘Details’.
<code>...</code>	(in <code>ordered(.)</code>): any of the above, apart from <code>ordered</code> itself.
<code>ifany</code>	only add an NA level if it is used, i.e. if <code>any(is.na(x))</code> .
<code>object</code>	an R object.

Details

The type of the vector `x` is not restricted; it only must have an `as.character` method and be sortable (by `order`).

Ordered factors differ from factors only in their class, but methods and model-fitting functions may treat the two classes quite differently, see `options("contrasts")`.

The encoding of the vector happens as follows. First all the values in `exclude` are removed from `levels`. If `x[i]` equals `levels[j]`, then the *i*-th element of the result is *j*. If no match is found for `x[i]` in `levels` (which will happen for excluded values) then the *i*-th element of the result is set to `NA`.

Normally the ‘levels’ used as an attribute of the result are the reduced set of levels after removing those in `exclude`, but this can be altered by supplying `labels`. This should either be a set of

new labels for the levels, or a character string, in which case the levels are that character string with a sequence number appended.

`factor(x, exclude = NULL)` applied to a factor without `NA`s is a no-operation unless there are unused levels: in that case, a factor with the reduced level set is returned. If `exclude` is used, since R version 3.4.0, excluding non-existing character levels is equivalent to excluding nothing, and when `exclude` is a `character` vector, that is applied to the levels of `x`. Alternatively, `exclude` can be factor with the same level set as `x` and will exclude the levels present in `exclude`.

The codes of a factor may contain `NA`. For a numeric `x`, set `exclude = NULL` to make `NA` an extra level (prints as '`<NA>`'); by default, this is the last level.

If `NA` is a level, the way to set a code to be missing (as opposed to the code of the missing level) is to use `is.na` on the left-hand-side of an assignment (as in `is.na(f)[i] <- TRUE`; indexing inside `is.na` does not work). Under those circumstances missing values are currently printed as '`<NA>`', i.e., identical to entries of level `NA`.

`is.factor` is generic: you can write methods to handle specific classes of objects, see [Internal-Methods](#).

Where `levels` is not supplied, `unique` is called. Since factors typically have quite a small number of levels, for large vectors `x` it is helpful to supply `nmax` as an upper bound on the number of unique values.

When using `c` to combine a (possibly ordered) factor with other objects, if all objects are (possibly ordered) factors, the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result), equivalent to how `unlist` operates on a list of factor objects.

Value

`factor` returns an object of class `"factor"` which has a set of integer codes the length of `x` with a `"levels"` attribute of mode `character` and unique (`!anyDuplicated(.)`) entries. If argument `ordered` is true (or `ordered()` is used) the result has class `c("ordered", "factor")`. Undocumented for a long time, `factor(x)` loses all `attributes(x)` but `"names"`, and resets `"levels"` and `"class"`.

Applying `factor` to an ordered or unordered factor returns a factor (of the same type) with just the levels which occur: see also `[.factor` for a more transparent way to achieve this.

`is.factor` returns `TRUE` or `FALSE` depending on whether its argument is of type factor or not. Correspondingly, `is.ordered` returns `TRUE` when its argument is an ordered factor and `FALSE` otherwise.

`as.factor` coerces its argument to a factor. It is an abbreviated (sometimes faster) form of `factor`.

`as.ordered(x)` returns `x` if this is ordered, and `ordered(x)` otherwise.

`addNA` modifies a factor by turning `NA` into an extra level (so that `NA` values are counted in tables, for instance).

`.valid.factor(object)` checks the validity of a factor, currently only `levels(object)`, and returns `TRUE` if it is valid, otherwise a string describing the validity problem. This function is used for `validObject(<factor>)`.

Warning

The interpretation of a factor depends on both the codes and the `"levels"` attribute. Be careful only to compare factors with the same set of levels (in the same order). In particular, `as.numeric`

applied to a factor is meaningless, and may happen by implicit coercion. To transform a factor `f` to approximately its original numeric values, `as.numeric(levels(f)) [f]` is recommended and slightly more efficient than `as.numeric(as.character(f))`.

The levels of a factor are by default sorted, but the sort order may well depend on the locale at the time of creation, and should not be assumed to be ASCII.

There are some anomalies associated with factors that have NA as a level. It is suggested to use them sparingly, e.g., only for tabulation purposes.

Comparison operators and group generic methods

There are "factor" and "ordered" methods for the [group generic Ops](#) which provide methods for the [Comparison](#) operators, and for the [min](#), [max](#), and [range](#) generics in [Summary](#) of "ordered". (The rest of the groups and the [Math](#) group generate an error as they are not meaningful for factors.)

Only `==` and `!=` can be used for factors: a factor can only be compared to another factor with an identical set of levels (not necessarily in the same ordering) or to a character vector. Ordered factors are compared in the same way, but the general dispatch mechanism precludes comparing ordered and unordered factors.

All the comparison operators are available for ordered factors. Collation is done by the levels of the operands: if both operands are ordered factors they must have the same level set.

Note

In earlier versions of R, storing character data as a factor was more space efficient if there is even a small proportion of repeats. However, identical character strings now share storage, so the difference is small in most cases. (Integer values are stored in 4 bytes whereas each reference to a character string needs a pointer of 4 or 8 bytes.)

See Also

[\[.factor\]](#) for subsetting of factors.

[gl](#) for construction of balanced factors and [C](#) for factors with specified contrasts. [levels](#) and [nlevels](#) for accessing the levels, and [unclass](#) to get integer codes.

Examples

```
(ff <- factor(substring("statistics", 1:10, 1:10), levels = letters))
as.integer(ff)           # the internal codes
(f. <- factor(ff))       # drops the levels that do not occur
ff[, drop = TRUE]        # the same, more transparently

factor(letters[1:20], labels = "letter")

class(ordered(4:1))      # "ordered", inheriting from "factor"
z <- factor(LETTERS[3:1], ordered = TRUE)
## and "relational" methods work:
stopifnot(sort(z)[c(1,3)] == range(z), min(z) < max(z))
```

```
## suppose you want "NA" as a level, and to allow missing values.
(x <- factor(c(1, 2, NA), exclude = NULL))
is.na(x)[2] <- TRUE
x # [1] 1      <NA> <NA>
is.na(x)
# [1] FALSE  TRUE  FALSE

## More rational, since R 3.4.0 :
factor(c(1:2, NA), exclude = "" ) # keeps <NA> , as
factor(c(1:2, NA), exclude = NULL) # always did
## exclude = <character>
z # ordered levels 'A < B < C'
factor(z, exclude = "C") # does exclude
factor(z, exclude = "B") # ditto

## Now, labels maybe duplicated:
## factor() with duplicated labels allowing to "merge levels"
x <- c("Man", "Male", "Man", "Lady", "Female")
## Map from 4 different values to only two levels:
(xf <- factor(x, levels = c("Male", "Man", "Lady", "Female"),
               labels = c("Male", "Male", "Female", "Female")))
#> [1] Male  Male  Male  Female Female
#> Levels: Male Female

## Using addNA()
Month <- airquality$Month
table(addNA(Month))
table(addNA(Month, ifany = TRUE))
```

file.access

Ascertain File Accessibility

Description

Utility function to access information about files on the user's file systems.

Usage

```
file.access(names, mode = 0)
```

Arguments

names	character vector containing file names. Tilde-expansion will be done: see path.expand .
mode	integer specifying access mode required: see 'Details'.

Details

The mode value can be the exclusive or (`xor`), i.e., a partial sum of the following values, and hence must be in `0:7`,

0 test for existence.

1 test for execute permission.

2 test for write permission.

4 test for read permission.

Permission will be computed for real user ID and real group ID (rather than the effective IDs).

Please note that it is not a good idea to use this function to test before trying to open a file. On a multi-tasking system, it is possible that the accessibility of a file will change between the time you call `file.access()` and the time you try to open the file. It is better to wrap file open attempts in `try`.

Value

An integer vector with values 0 for success and -1 for failure.

Note

This was written as a replacement for the S-PLUS function `access`, a wrapper for the C function of the same name, which explains the return value encoding. Note that the return value is **false** for **success**.

See Also

`file.info` for more details on permissions, `Sys.chmod` to change permissions, and `try` for a ‘test it and see’ approach.

`file_test` for shell-style file tests.

Examples

```
fa <- file.access(dir("."))

table(fa) # count successes & failures
```

file.choose	<i>Choose a File Interactively</i>
-------------	------------------------------------

Description

Choose a file interactively.

Usage

```
file.choose(new = FALSE)
```

Arguments

new	Logical: choose the style of dialog box presented to the user: at present only new = FALSE is used.
-----	---

Value

A character vector of length one giving the file path.

See Also

[list.files](#) for non-interactive selection.

file.info

Extract File Information

Description

Utility function to extract information about files on the user's file systems.

Usage

```
file.info(..., extra_cols = TRUE)

file.mode(...)
file.mtime(...)
file.size(...)
```

Arguments

... character vectors containing file paths. Tilde-expansion is done: see [path.expand](#).

extra_cols logical: return all cols rather than just the first six.

Details

What constitutes a 'file' is OS-dependent but includes directories. (However, directory names must not include a trailing backslash or slash on Windows.) See also the section in the help for [file.exists](#) on case-insensitive file systems.

The file 'mode' follows POSIX conventions, giving three octal digits summarizing the permissions for the file owner, the owner's group and for anyone respectively. Each digit is the logical *or* of read (4), write (2) and execute/search (1) permissions.

See [files](#) for how file paths with marked encodings are interpreted.

On unix alike: On most systems symbolic links are followed, so information is given about the file to which the link points rather than about the link.

On Windows: File modes are probably only useful on NTFS file systems, and it seems all three digits refer to the file's owner. The execute/search bits are set for directories, and for files based on their extensions (e.g., '.exe', '.com', '.cmd' and '.bat' files). [file.access](#) will give a more reliable view of read/write access availability to the R process.

UTF-8-encoded file names not valid in the current locale can be used.

Junction points and symbolic links are followed, so information is given about the file/directory to which the link points rather than about the link.

Value

For `file.info()`, data frame with row names the file names and columns

<code>size</code>	double: File size in bytes.
<code>isdir</code>	logical: Is the file a directory?
<code>mode</code>	integer of class <code>"octmode"</code> . The file permissions, printed in octal, for example 644.
<code>mtime, ctime, atime</code>	object of class <code>"POSIXct"</code> : file modification, 'last status change' and last access times.

On unix alike: **uid:** integer, the user ID of the file's owner.

gid: integer, the group ID of the file's group.

uname: character, uid interpreted as a user name.

grname: character, gid interpreted as a group name. Unknown user and group names will be NA.

On Windows only: **exe:** character indicating the sort of executable. Possible values are `"no"`, `"msdos"`, `"win16"`, `"win32"`, `"win64"` and `"unknown"`. Note that a file (e.g., a script file) can be executable according to the mode bits but not executable in this sense.

uname: character, user name.

udomain: character, user domain name. User name and domain will be NA when they cannot be resolved, e.g. because of insufficient permissions or a network failure.

If `extra_cols` is false, only the first six columns are returned: as these can all be found from a single C system call this can be faster. (However, properly configured systems will use a 'name service cache daemon' to speed up the name lookups.)

Entries for non-existent or non-readable files will be NA.

The `uid`, `gid`, `uname` and `grname` columns may not be supplied on a non-POSIX Unix-alike system, and except `uname` will not be on Windows.

What is meant by the three file times depends on the OS and file system. On Windows native file systems `ctime` is the file creation time (something which is not recorded on most Unix-alike file systems). What is meant by 'file access' and hence the 'last access time' is system-dependent.

The resolution of the file times depends on both the OS and the type of the file system. Modern file systems typically record times to an accuracy of a microsecond or better: notable exceptions are HFS+ on macOS (recorded in seconds) and modification time on older FAT systems (recorded in increments of 2 seconds). Note that `"POSIXct"` times are by default printed in whole seconds: to change that see [strftime](#).

`file.mode()`, `file.mtime()` and `file.size()` are fast convenience wrappers returning just one of the columns.

Note

Some (now old) unix alike systems allow files of more than 2Gb to be created but not accessed by the `stat` system call. Such files may show up as non-readable (and very likely not be readable by any of R's input functions).

See Also

[Sys.readlink](#) to find out about symbolic links, [files](#), [file.access](#), [list.files](#), and [DateTimeClasses](#) for the date formats.

[Sys.chmod](#) to change permissions.

Examples

```
ncol(finf <- file.info(dir())) # at least six
finf # the whole list
## Those that are more than 100 days old :
finf <- file.info(dir(), extra_cols = FALSE)
finf[difftime(Sys.time(), finf[, "mtime"], units = "days") > 100 , 1:4]

file.info("no-such-file-exists")

## E.g., for R-core, in a R-devel version:
if(Sys.info()[["sysname"]] == "Linux")
  sort(file.mtime(file.path(R.home("bin"),
                           c("",
                               file.path(c("", "exec"), "R"))))
      ))
```

file.path

*Construct Path to File***Description**

Construct the path to a file from components in a platform-independent way.

Usage

```
file.path(..., fsep = .Platform$file.sep)
```

Arguments

... character vectors. [Long vectors](#) are not supported.
 fsep the path separator to use (assumed to be ASCII).

Details

The implementation is designed to be fast (faster than [paste](#)) as this function is used extensively in R itself.

It can also be used for environment paths such as PATH and R_LIBS with fsep = .Platform\$path.sep.

Trailing path separators are invalid for Windows file paths apart from ‘/’ and ‘d: /’ (although some functions/utilities do accept them), so a trailing / or \ is removed there.

Value

A character vector of the arguments concatenated term-by-term and separated by fsep if all arguments have positive length; otherwise, an empty character vector (unlike [paste](#)).

An element of the result will be marked (see [Encoding](#)) as UTF-8 if run in a UTF-8 locale (when marked inputs are converted to UTF-8) or if a component of the result is marked as UTF-8, or as Latin-1 in a non-Latin-1 locale.

Note

The components are by default separated by / (not \) on Windows.

See Also

[basename](#), [normalizePath](#), [path.expand](#).

file.show

Display One or More Text Files

Description

Display one or more (plain) text files, in a platform-specific way, typically via a ‘pager’.

Usage

```
file.show(..., header = rep("", nfiles),
          title = "R Information",
          delete.file = FALSE, pager = getOption("pager"),
          encoding = "")
```

Arguments

...	one or more character vectors containing the names of the files to be displayed. Paths will undergo tilde expansion .
header	character vector (of the same length as the number of files specified in ...) giving a header for each file being displayed. Defaults to empty strings.
title	an overall title for the display. If a single separate window is used for the display, title will be used as the window title. If multiple windows are used, their titles should combine the title and the file-specific header.
delete.file	should the files be deleted after display? Used for temporary files.
pager	the pager to be used, see ‘Details’.
encoding	character string giving the encoding to be assumed for the file(s).

Details

This function provides the core of the R help system, but it can be used for other purposes as well, such as [page](#).

How the pager is implemented is highly system-dependent.

The basic Unix version concatenates the files (using the headers) to a temporary file, and displays it in the pager selected by the `pager` argument, which is a character vector specifying a system command (a full path or a command found on the `PATH`) to run on the set of files. The ‘factory-fresh’ default is to use ‘`R_HOME/bin/pager`’, which is a shell script running the command-line specified by the environment variable `PAGER` whose default is set at configuration, usually to `less`. On a Unix-alike `more` is used if `pager` is empty.

Most GUI systems will use a separate pager window for each file, and let the user leave it up while R continues running. The selection of such pagers could either be done using special pager names being intercepted by lower-level code (such as “`internal`” and “`console`” on Windows), or by letting `pager` be an R function which will be called with arguments (`files`, `header`, `title`, `delete.file`) corresponding to the first four arguments of `file.show` and take care of interfacing to the GUI.

The R.app GUI on macOS uses its internal pager irrespective of the setting of `pager`.

Not all implementations will honour `delete.file`. In particular, using an external pager on Windows does not, as there is no way to know when the external application has finished with the file.

Examples

```
file.show(file.path(R.home("doc"), "COPYRIGHTS"))
```

files

File Manipulation

Description

These functions provide a low-level interface to the computer's file system.

Usage

```
file.create(..., showWarnings = TRUE)
file.exists(...)
file.remove(...)
file.rename(from, to)
file.append(file1, file2)
file.copy(from, to, overwrite = recursive, recursive = FALSE,
          copy.mode = TRUE, copy.date = FALSE)
file.symlink(from, to)
file.link(from, to)
```

Arguments

<code>..., file1, file2</code>	character vectors, containing file names or paths.
<code>from, to</code>	character vectors, containing file names or paths. For <code>file.copy</code> and <code>file.symlink</code> <code>to</code> can alternatively be the path to a single existing directory.
<code>overwrite</code>	logical; should existing destination files be overwritten?
<code>showWarnings</code>	logical; should the warnings on failure be shown?
<code>recursive</code>	logical. If <code>to</code> is a directory, should directories in <code>from</code> be copied (and their contents)? (Like <code>cp -R</code> on POSIX OSes.)
<code>copy.mode</code>	logical: should file permission bits be copied where possible?
<code>copy.date</code>	logical: should file dates be preserved where possible? See <code>Sys.setFileTime</code> .

Details

The ... arguments are concatenated to form one character string: you can specify the files separately or as one vector. All of these functions expand path names: see [path.expand](#). (`file.exists` silently reports false for paths that would be too long after expansion: the rest will give a warning.)

`file.create` creates files with the given names if they do not already exist and truncates them if they do. They are created with the maximal read/write permissions allowed by the ‘[umask](#)’ setting (where relevant). By default a warning is given (with the reason) if the operation fails.

`file.exists` returns a logical vector indicating whether the files named by its argument exist. (Here ‘exists’ is in the sense of the system’s `stat` call: a file will be reported as existing only if you have the permissions needed by `stat`. Existence can also be checked by [file.access](#), which might use different permissions and so obtain a different result. Note that the existence of a file does not imply that it is readable: for that use [file.access](#).) What constitutes a ‘file’ is system-dependent, but should include directories. (However, directory names must not include a trailing backslash or slash on Windows.) Note that if the file is a symbolic link on a Unix-alike, the result indicates if the link points to an actual file, not just if the link exists. On Windows, the result is unreliable for a broken symbolic link (junction). Lastly, note the *different* function [exists](#) which checks for existence of R objects.

`file.remove` attempts to remove the files named in its argument. On most Unix platforms ‘file’ includes *empty* directories, symbolic links, fifos and sockets. On Windows, ‘file’ means a regular file and not, say, an empty directory.

`file.rename` attempts to rename files (and `from` and `to` must be of the same length). Where file permissions allow this will overwrite an existing element of `to`. This is subject to the limitations of the OS’s corresponding system call (see something like `man 2 rename` on a Unix-alike): in particular in the interpretation of ‘file’: most platforms will not rename files from one file system to another. **NB:** This means that renaming a file from a temporary directory to the user’s filesystem or during package installation will often fail. (On Windows, `file.rename` can rename files but not directories across volumes.) On platforms which allow directories to be renamed, typically neither or both of `from` and `to` must a directory, and if `to` exists it must be an empty directory.

`file.append` attempts to append the files named by its second argument to those named by its first. The R subscript recycling rule is used to align names given in vectors of different lengths.

`file.copy` works in a similar way to `file.append` but with the arguments in the natural order for copying. Copying to existing destination files is skipped unless `overwrite = TRUE`. The `to` argument can specify a single existing directory. If `copy.mode = TRUE` file read/write/execute permissions are copied where possible, restricted by ‘[umask](#)’. (On Windows this applies only to files.) Other security attributes such as ACLs are not copied. On a POSIX filesystem the targets of symbolic links will be copied rather than the links themselves, and hard links are copied separately. Using `copy.date = TRUE` may or may not copy the timestamp exactly (for example, fractional seconds may be omitted), but is more likely to do so as from R 3.4.0.

`file.symlink` and `file.link` make symbolic and hard links on those file systems which support them. For `file.symlink` the `to` argument can specify a single existing directory. (Unix and macOS native filesystems support both. Windows has hard links to files on NTFS file systems and concepts related to symbolic links on recent versions: see the section below on the Windows version of this help page. What happens on a FAT or SMB-mounted file system is OS-specific.)

File arguments with a marked encoding (see [Encoding](#)) are if possible translated to the native encoding, except on Windows where Unicode file operations are used (so marking as UTF-8 can be used to access file paths not in the native encoding on suitable file systems).

Value

These functions return a logical vector indicating which operation succeeded for each of the files attempted. Using a missing value for a file or path name will always be regarded as a failure.

If `showWarnings = TRUE`, `file.create` will give a warning for an unexpected failure.

Case-insensitive file systems

Case-insensitive file systems are the norm on Windows and macOS, but can be found on all OSes (for example a FAT-formatted USB drive is probably case-insensitive).

These functions will most likely match existing files regardless of case on such file systems: however this is an OS function and it is possible that file names might be mapped to upper or lower case.

Warning

Always check the return value of these functions when used in package code. This is especially important for `file.rename`, which has OS-specific restrictions (and note that the session temporary directory is commonly on a different file system from the working directory): it is only portable to use `file.rename` to change file name(s) within a single directory.

Examples

```
cat("file A\n", file = "A")
cat("file B\n", file = "B")
file.append("A", "B")
file.create("A") # (trashing previous)
file.append("A", rep("B", 10))
if(interactive()) file.show("A") # -> the 10 lines from 'B'
file.copy("A", "C")
dir.create("tmp")
file.copy(c("A", "B"), "tmp")
list.files("tmp") # -> "A" and "B"
setwd("tmp")
file.remove("A") # the tmp/A file
file.symlink(file.path("../", c("A", "B")), ".")
# |--> (TRUE,FALSE) : ok for A but not B as it exists already
setwd("../")
unlink("tmp", recursive = TRUE)
```

```
file.remove("A", "B", "C")
```

files2

Manipulation of Directories and File Permissions

Description

These functions provide a low-level interface to the computer's file system.

Usage

```
dir.exists(paths)
dir.create(path, showWarnings = TRUE, recursive = FALSE, mode = "0777")
Sys.chmod(paths, mode = "0777", use_umask = TRUE)
Sys.umask(mode = NA)
```

Arguments

<code>path</code>	a character vector containing a single path name. Tilde expansion (see path.expand) is done. Necessarily a non-empty string.
<code>paths</code>	character vectors containing file or directory paths. Tilde expansion (see path.expand) is done.
<code>showWarnings</code>	logical; should the warnings on failure be shown?
<code>recursive</code>	logical. Should elements of the path other than the last be created? If true, like the Unix command <code>mkdir -p</code> .
<code>mode</code>	the mode to be used on Unix-alikes: it will be coerced by as.octmode . For <code>Sys.chmod</code> it is recycled along <code>paths</code> .
<code>use_umask</code>	logical: should the mode be restricted by the <code>umask</code> setting?

Details

`dir.exists` checks that the paths exist (in the same sense as [file.exists](#)) and are directories.

`dir.create` creates the last element of the path, unless `recursive = TRUE`. Trailing path separators are discarded. The mode will be modified by the `umask` setting in the same way as for the system function `mkdir`. What modes can be set is OS-dependent, and it is unsafe to assume that more than three octal digits will be used. For more details see your OS's documentation on the system call `mkdir`, e.g. `man 2 mkdir` (and not that on the command-line utility of that name).

One of the idiosyncrasies of Windows is that directory creation may report success but create a directory with a different name, for example `dir.create("G.S.")` creates `"G.S"`. This is undocumented, and what are the precise circumstances is unknown (and might depend on the version of Windows). Also avoid directory names with a trailing space.

`Sys.chmod` sets the file permissions of one or more files. It may not be supported on a system (when a warning is issued). See the comments for `dir.create` for how modes are interpreted. Changing mode on a symbolic link is unlikely to work (nor be necessary). For more details see your OS's documentation on the system call `chmod`, e.g. `man 2 chmod` (and not that on the command-line utility of that name). Whether this changes the permission of a symbolic link or its target is

OS-dependent (although to change the target is more common, and POSIX does not support modes for symbolic links: BSD-based Unixes do, though).

`Sys.umask` sets the `umask` and returns the previous value: as a special case `mode = NA` just returns the current value. It may not be supported (when a warning is issued and `"0"` is returned). For more details see your OS's documentation on the system call `umask`, e.g. `man 2 umask`.

How modes are handled depends on the file system, even on Unix-alikes (although their documentation is often written assuming a POSIX file system). So treat documentation cautiously if you are using, say, a FAT/FAT32 or network-mounted file system.

See the help on [files](#) for how file paths with marked encodings are interpreted.

Value

`dir.exists` returns a logical vector of `TRUE` or `FALSE` values (without names).

`dir.create` and `Sys.chmod` return invisibly a logical vector indicating if the operation succeeded for each of the files attempted. Using a missing value for a path name will always be regarded as a failure. `dir.create` indicates failure if the directory already exists. If `showWarnings = TRUE`, `dir.create` will give a warning for an unexpected failure (e.g., not for a missing value nor for an already existing component for `recursive = TRUE`).

`Sys.umask` returns the previous value of the `umask`, as a length-one object of class `"octmode"`: the visibility flag is off unless `mode` is `NA`.

See also the section in the help for [file.exists](#) on case-insensitive file systems for the interpretation of `path` and `paths`.

[file.info](#), [file.exists](#), [file.path](#), [list.files](#), [unlink](#), [basename](#), [path.expand](#).

Examples

```
## Not run:
## Fix up maximal allowed permissions in a file tree
Sys.chmod(list.dirs("."), "777")
f <- list.files(".", all.files = TRUE, full.names = TRUE, recursive = TRUE)
Sys.chmod(f, (file.mode(f) | "664"))

## End(Not run)
```

find.package

Find Packages

Description

Find the paths to one or more packages.

Usage

```
find.package(package, lib.loc = NULL, quiet = FALSE,
             verbose = getOption("verbose"))

path.package(package, quiet = FALSE)

packageNotFoundError(package, lib.loc, call = NULL)
```

Arguments

<code>package</code>	character vector: the names of packages.
<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to checking the loaded namespaces, then all libraries currently known in <code>.libPaths()</code> .
<code>quiet</code>	logical. Should this not give warnings or an error if the package is not found?
<code>verbose</code>	a logical. If TRUE, additional diagnostics are printed, notably when a package is found more than once.
<code>call</code>	call expression.

Details

`find.package` returns the paths to the locations where the given packages are found. If `lib.loc` is NULL, then loaded namespaces are searched before the libraries. If a package is found more than once, the first match is used. Unless `quiet = TRUE` a warning will be given about the named packages which are not found, and an error if none are. If `verbose` is true, warnings about packages found more than once are given. For a package to be returned it must contain either a 'Meta' subdirectory or a 'DESCRIPTION' file containing a valid `version` field, but it need not be installed (it could be a source package if `lib.loc` was set suitably).

`find.package` is not usually the right tool to find out if a package is available for use: the only way to do that is to use `require` to try to load it. It need not be installed for the correct platform, it might have a version requirement not met by the running version of R, there might be dependencies which are not available, ...

`path.package` returns the paths from which the named packages were loaded, or if none were named, for all currently attached packages. Unless `quiet = TRUE` it will warn if some of the packages named are not attached, and give an error if none are.

`packageNotFoundError` creates an error condition object of class `packageNotFoundError` for signaling errors. The condition object contains the fields `package` and `lib.loc`.

Value

A character vector of paths of package directories.

See Also

`path.expand` and `normalizePath` for path standardization.

Examples

```
try(find.package("knitr"))
## will not give an error, maybe a warning about *all* locations it is found:
find.package("kitty", quiet=TRUE, verbose=TRUE)

## Find all .libPaths() entries a package is found:
findPkgAll <- function(pkg)
  unlist(lapply(.libPaths(), function(lib)
    find.package(pkg, lib, quiet=TRUE, verbose=FALSE)))

findPkgAll("MASS")
findPkgAll("knitr")
```

findInterval

Find Interval Numbers or Indices

Description

Given a vector of non-decreasing breakpoints in `vec`, find the interval containing each element of `x`; i.e., if `i <- findInterval(x, v)`, for each index `j` in `x` $v_{i_j} \leq x_j < v_{i_j+1}$ where $v_0 := -\infty$, $v_{N+1} := +\infty$, and $N <- \text{length}(v)$. At the two boundaries, the returned index may differ by 1, depending on the optional arguments `rightmost.closed` and `all.inside`.

Usage

```
findInterval(x, vec, rightmost.closed = FALSE, all.inside = FALSE,
  left.open = FALSE, checkSorted = TRUE, checkNA = TRUE)
```

Arguments

<code>x</code>	numeric.
<code>vec</code>	numeric, sorted (weakly) increasingly, of length <code>N</code> , say.
<code>rightmost.closed</code>	logical; if true, the rightmost interval, <code>vec[N-1] .. vec[N]</code> is treated as <i>closed</i> , see below.
<code>all.inside</code>	logical; if true, the returned indices are coerced into <code>1, ..., N-1</code> , i.e., 0 is mapped to 1 and <code>N</code> to <code>N-1</code> .
<code>left.open</code>	logical; if true all the intervals are open at left and closed at right; in the formulas below, $\leq$ should be swapped with $<$ (and $>$ with $\geq$), and <code>rightmost.closed</code> means ‘leftmost is closed’. This may be useful, e.g., in survival analysis computations.
<code>checkSorted</code>	logical indicating if <code>vec</code> should be checked, i.e., <code>is.unsorted(vec)</code> is asserted to be false. Setting this to <code>FALSE</code> skips the check gaining speed, but may return nonsense results in case <code>vec</code> is not sorted.
<code>checkNA</code>	logical indicating if each <code>x[i]</code> should be checked as with <code>is.na(.)</code> . Setting this to <code>FALSE</code> in case of NAs in <code>x[]</code> may result in platform-dependent nonsense.

Details

The function `findInterval` finds the index of one vector `x` in another, `vec`, where the latter must be non-decreasing. Where this is trivial, equivalent to `apply(outer(x, vec, `>=`), 1, sum)`, as a matter of fact, the internal algorithm uses interval search ensuring $O(n \log N)$ complexity where `n <- length(x)` (and `N <- length(vec)`). For (almost) sorted `x`, it will be even faster, basically $O(n)$.

This is the same computation as for the empirical distribution function, and indeed, `findInterval(t, sort(X))` is *identical* to $nF_n(t; X_1, \dots, X_n)$ where F_n is the empirical distribution function of $X_1, \dots, X_n$.

When `rightmost.closed = TRUE`, the result for `x[j] = vec[N]` ($= \max vec$), is `N - 1` as for all other values in the last interval.

`left.open = TRUE` is occasionally useful, e.g., for survival data. For (anti-)symmetry reasons, it is equivalent to using “mirrored” data, i.e., the following is always true:

```
identical(
  findInterval(x, v, left.open= TRUE, ...) ,
  N - findInterval(-x, -v[N:1], left.open=FALSE, ...) )
```

where `N <- length(vec)` as above.

Value

vector of length `length(x)` with values in `0:N` (and `NA`) where `N <- length(vec)`, or values coerced to `1:(N-1)` if and only if `all.inside = TRUE` (equivalently coercing all `x` values *inside* the intervals). Note that `NAs` are propagated from `x`, and `Inf` values are allowed in both `x` and `vec`.

Author(s)

Martin Maechler

See Also

`approx(*, method = "constant")` which is a generalization of `findInterval()`, `ecdf` for computing the empirical distribution function which is (up to a factor of n) also basically the same as `findInterval(.)`.

Examples

```
x <- 2:18
v <- c(5, 10, 15) # create two bins [5,10) and [10,15)
cbind(x, findInterval(x, v))

N <- 100
X <- sort(round(stats::rt(N, df = 2), 2))
tt <- c(-100, seq(-2, 2, length.out = 201), +100)
it <- findInterval(tt, X)
tt[it < 1 | it >= N] # only first and last are outside range(X)
stopifnot(identical(it,
  ## Suppressing the checks is faster *BUT* dangerous, unless
  ## you *know* (like here) that the breakpoints are sorted
  ## and the input contains no missing values, respectively.
```

```

    findInterval(tt, X, checkSorted=FALSE, checkNA=FALSE)
  )

  ## 'left.open = TRUE' means "mirroring" :
  N <- length(v)
  stopifnot(identical(
    findInterval(x, v, left.open=TRUE) ,
    N - findInterval(-x, -v[N:1])))

```

 force

Force Evaluation of an Argument

Description

Forces the evaluation of a function argument.

Usage

```
force(x)
```

Arguments

x a formal argument of the enclosing function.

Details

`force` forces the evaluation of a formal argument. This can be useful if the argument will be captured in a closure by the lexical scoping rules and will later be altered by an explicit assignment or an implicit assignment in a loop or an apply function.

Note

This is semantic sugar: just evaluating the symbol will do the same thing (see the examples).

`force` does not force the evaluation of other [promises](#). (It works by forcing the promise that is created when the actual arguments of a call are matched to the formal arguments of a closure, the mechanism which implements *lazy evaluation*.)

Examples

```

f <- function(y) function() y
lf <- vector("list", 5)
for (i in seq_along(lf)) lf[[i]] <- f(i)
lf[[1]]() # returns 5

g <- function(y) { force(y); function() y }
lg <- vector("list", 5)
for (i in seq_along(lg)) lg[[i]] <- g(i)
lg[[1]]() # returns 1

## This is identical to
g <- function(y) { y; function() y }

```

forceAndCall	<i>Call a function with Some Arguments Forced</i>
--------------	---

Description

Call a function with a specified number of leading arguments forced before the call if the function is a closure.

Usage

```
forceAndCall(n, FUN, ...)
```

Arguments

n	number of leading arguments to force.
FUN	function to call.
...	arguments to FUN.

Details

`forceAndCall` calls the function `FUN` with arguments specified in `...`. If the value of `FUN` is a closure then the first `n` arguments to the function are evaluated (i.e. their delayed evaluation promises are forced) before executing the function body. If the value of `FUN` is a primitive then the call `FUN(...)` is evaluated in the usual way.

`forceAndCall` is intended to help defining higher order functions like [apply](#) to behave more reasonably when the result returned by the function applied is a closure that captured its arguments.

See Also

[force](#), [promise](#), [closure](#).

Foreign	<i>Foreign Function Interface</i>
---------	-----------------------------------

Description

Functions to make calls to compiled code that has been loaded into R.

Usage

```
.C(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.Fortran(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
```

Arguments

<code>.NAME</code>	a character string giving the name of a C function or Fortran subroutine, or an object of class <code>"NativeSymbolInfo"</code> , <code>"RegisteredNativeSymbol"</code> or <code>"NativeSymbol"</code> referring to such a name.
<code>...</code>	arguments to be passed to the foreign function. Up to 65.
<code>NAOK</code>	if TRUE then any <code>NA</code> or <code>NaN</code> or <code>Inf</code> values in the arguments are passed on to the foreign function. If FALSE, the presence of <code>NA</code> or <code>NaN</code> or <code>Inf</code> values is regarded as an error.
<code>PACKAGE</code>	if supplied, confine the search for a character string <code>.NAME</code> to the DLL given by this argument (plus the conventional extension, <code>' .so'</code> , <code>' .dll'</code> , ...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see 'Note').
<code>DUP, ENCODING</code>	For back-compatibility, accepted but ignored.

Details

These functions can be used to make calls to compiled C and Fortran code. Later interfaces are `.Call` and `.External` which are more flexible and have better performance.

These functions are `primitive`, and `.NAME` is always matched to the first argument supplied (which should not be named). The other named arguments follow `...` and so cannot be abbreviated. For clarity, should avoid using names in the arguments passed to `...` that match or partially match `.NAME`.

Value

A list similar to the `...` list of arguments passed in (including any names given to the arguments), but reflecting any changes made by the C or Fortran code.

Argument types

The mapping of the types of R arguments to C or Fortran arguments is

R	C	Fortran
integer	int *	integer
numeric	double *	double precision
– or –	float *	real
complex	Rcomplex *	double complex
logical	int *	integer
character	char **	[see below]
raw	unsigned char *	not allowed
list	SEXP *	not allowed
other	SEXP	not allowed

Note: The C types corresponding to `integer` and `logical` are `int`, not `long` as in S. This difference matters on most 64-bit platforms, where `int` is 32-bit and `long` is 64-bit (but not on 64-bit Windows).

Note: The Fortran type corresponding to `logical` is `integer`, not `logical`: the difference matters on some Fortran compilers.

Numeric vectors in R will be passed as type `double *` to C (and as `double precision` to Fortran) unless the argument has attribute `Csingle` set to `TRUE` (use `as.single` or `single`). This mechanism is only intended to be used to facilitate the interfacing of existing C and Fortran code.

The C type `Rcomplex` is defined in `'Complex.h'` as a `typedef struct {double r; double i;}`. It may or may not be equivalent to the C99 `double complex` type, depending on the compiler used.

Logical values are sent as 0 (`FALSE`), 1 (`TRUE`) or `INT_MIN = -2147483648` (`NA`, but only if `NAOK = TRUE`), and the compiled code should return one of these three values: however non-zero values other than `INT_MIN` are mapped to `TRUE`.

Missing (`NA`) string values are passed to `.C` as the string `"NA"`. As the C `char` type can represent all possible bit patterns there appears to be no way to distinguish missing strings from the string `"NA"`. If this distinction is important use `.Call`.

Using a character string with `.Fortran` is deprecated and will give a warning. It passes the first (only) character string of a character vector as a C character array to Fortran: that may be usable as `character*255` if its true length is passed separately. Only up to 255 characters of the string are passed back. (How well this works, and even if it works at all, depends on the C and Fortran compilers and the platform.)

Lists, functions or other R objects can (for historical reasons) be passed to `.C`, but the `.Call` interface is much preferred. All inputs apart from atomic vectors should be regarded as read-only, and all apart from vectors (including lists), functions and environments are now deprecated.

Fortran symbol names

All Fortran compilers known to be usable to compile R map symbol names to lower case, and so does `.Fortran`.

Symbol names containing underscores are not valid Fortran 77 (although they are valid in Fortran 9x). Many Fortran 77 compilers will allow them but may translate them in a different way to names not containing underscores. Such names will often work with `.Fortran` (since how they are translated is detected when R is built and the information used by `.Fortran`), but portable code should not use Fortran names containing underscores.

Use `.Fortran` with care for compiled Fortran 9x code: it may not work if the Fortran 9x compiler used differs from the Fortran compiler used when configuring R, especially if the subroutine name is not lower-case or includes an underscore. The most portable way to call Fortran 9x code from R is to use `.C` and the Fortran 2003 module `iso_c_binding` to provide a C interface to the Fortran code.

Copying of arguments

Character vectors are copied before calling the compiled code and to collect the results. For other atomic vectors the argument is copied before calling the compiled code if it is otherwise used in the calling code.

Non-atomic-vector objects are read-only to the C code and are never copied.

This behaviour can be changed by setting `options(CBoundsCheck = TRUE)`. In that case raw, logical, integer, double and complex vector arguments are copied both before and after calling the compiled code. The first copy made is extended at each end by guard bytes, and on return it is checked that these are unaltered. For `.C`, each element of a character vector uses guard bytes.

Note

If one of these functions is to be used frequently, do specify `PACKAGE` (to confine the search to a single DLL) or pass `.NAME` as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see `PACKAGE = "base"` for symbols linked into R. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.

formals

Access to and Manipulation of the Formal Arguments

Description

Get or set the formal arguments of a `function`.

Usage

```
formals(fun = sys.function(sys.parent()), envir = parent.frame())
formals(fun, envir = environment(fun)) <- value
```

Arguments

<code>fun</code>	a <code>function</code> , or see ‘Details’.
<code>envir</code>	<code>environment</code> in which the function should be defined (or found via <code>get()</code> in the first case and when <code>fun</code> a character string).
<code>value</code>	a <code>list</code> (or <code>pairlist</code> , hence possibly <code>NULL</code>) of R expressions.

Details

For the first form, `fun` can also be a character string naming the function to be manipulated, which is searched for in `envir`, by default from the parent frame. If it is not specified, the function calling `formals` is used.

Only *closures*, i.e., non-primitive functions, have formals, not primitive functions.

Note that `formals(args(f))` gives a formal argument list for all functions `f`, primitive or not.

Value

`formals` returns the formal argument list of the function specified, as a `pairlist`, or `NULL` for a non-function or primitive.

The replacement form sets the formals of a function to the list/pairlist on the right hand side, and (potentially) resets the environment of the function, dropping `attributes`.

See Also

`formalArgs` (from **methods**), a shortcut for `names(formals(.))`. `args` for a human-readable version, *and* as intermediary to get `formals` of a primitive function. `alist` to *construct* a typical `formals` value, see the examples.

The three parts of a (non-primitive) `function` are its `formals`, `body`, and `environment`.

Examples

```
require(stats)
formals(lm)

## If you just want the names of the arguments, use formalArgs instead.
names(formals(lm))
methods::formalArgs(lm)      # same

## formals returns a pairlist. Arguments with no default have type symbol (aka name).
str(formals(lm))

## formals returns NULL for primitive functions. Use it in combination with
## args for this case.
is.primitive(`+`)
formals(`+`)
formals(args(`+`))

## You can overwrite the formal arguments of a function (though this is
## advanced, dangerous coding).
f <- function(x) a + b
formals(f) <- alist(a = , b = 3)
f      # function(a, b = 3) a + b
f(2)   # result = 5
```

format

Encode in a Common Format

Description

Format an R object for pretty printing, notably encoding vector or column elements into a common format.

Usage

```
format(x, ...)
```

Default S3 method:

```
format(x, trim = FALSE, digits = NULL, nsmall = 0L,
       justify = c("left", "right", "centre", "none"),
       width = NULL, na.encode = TRUE, scientific = NA,
       big.mark = "", big.interval = 3L,
       small.mark = "", small.interval = 5L,
       decimal.mark = getOption("OutDec"),
       zero.print = NULL, drop0trailing = FALSE, ...)
```

```
## S3 method for class 'data.frame'
format(x, ..., justify = "none", cut.names = TRUE)

## S3 method for class 'factor'
format(x, ...)

## S3 method for class 'AsIs'
format(x, width = 12, ...)
```

Arguments

<code>x</code>	any R object (conceptually); typically numeric.
<code>trim</code>	logical; if FALSE, logical, numeric and complex values are right-justified to a common width: if TRUE the leading blanks for justification are suppressed.
<code>digits</code>	a positive integer indicating how many significant digits are to be used for numeric and complex <code>x</code> . The default, NULL, uses <code>getOption("digits")</code> . This is a suggestion: enough decimal places will be used so that the smallest (in magnitude) number has this many significant digits, and also to satisfy <code>nsmall</code> . (For more, notably the interpretation for complex numbers see signif .)
<code>nsmall</code>	the minimum number of digits to the right of the decimal point in formatting real/complex numbers in non-scientific formats. Allowed values are $0 \leq \text{nsmall} \leq 20$.
<code>justify</code>	should a <i>character</i> vector be left-justified (the default), right-justified, centred or left alone. Can be abbreviated.
<code>cut.names</code>	logical passed to the <code>list</code> method of <code>as.data.frame()</code> .
<code>width</code>	default method: the <i>minimum</i> field width or NULL or 0 for no restriction. AsIs method: the <i>maximum</i> field width for non-character objects. NULL corresponds to the default 12.
<code>na.encode</code>	logical: should NA strings be encoded? Note this only applies to elements of character vectors, not to numerical, complex nor logical NAs, which are always encoded as "NA".
<code>scientific</code>	either a logical specifying whether elements of a real or complex vector should be encoded in scientific format, or an integer penalty (see options("scipen")). Missing values correspond to the current default penalty.
<code>...</code>	further arguments passed to or from other methods.
<code>big.mark</code> , <code>big.interval</code> , <code>small.mark</code> , <code>small.interval</code> , <code>decimal.mark</code> , <code>zero.print</code> , <code>drop0trailing</code>	used for prettying (longish) numerical and complex sequences. Passed to prettyNum : that help page explains the details.

Details

`format` is a generic function. Apart from the methods described here there are methods for dates (see [format.Date](#)), date-times (see [format.POSIXct](#)) and for other classes such as `format.octmode` and `format.dist`.

`format.data.frame` formats the data frame column by column, applying the appropriate method of `format` for each column. Methods for columns are often similar to `as.character` but offer more control. Matrix and data-frame columns will be converted to separate columns in the result, and character columns (normally all) will be given class "[AsIs](#)".

`format.factor` converts the factor to a character vector and then calls the default method (and so `justify` applies).

`format.AsIs` deals with columns of complicated objects that have been extracted from a data frame. Character objects and (atomic) matrices are passed to the default method (and so `width` does not apply). Otherwise it calls `toString` to convert the object to character (if a vector or list, element by element) and then right-justifies the result.

Justification for character vectors (and objects converted to character vectors by their methods) is done on display width (see `nchar`), taking double-width characters and the rendering of special characters (as escape sequences, including escaping backslash but not double quote: see `print.default`) into account. Thus the width is as displayed by `print(quote = FALSE)` and not as displayed by `cat`. Character strings are padded with blanks to the display width of the widest. (If `na.encode = FALSE` missing character strings are not included in the width computations and are not encoded.)

Numeric vectors are encoded with the minimum number of decimal places needed to display all the elements to at least the `digits` significant digits. However, if all the elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit; see also the argument documentation for `big.*`, `small.*` etc, above. See the note in `print.default` about `digits >= 16`.

Raw vectors are converted to their 2-digit hexadecimal representation by `as.character`.

`format.default(x)` now provides a “minimal” string when `isS4(x)` is true.

While the internal code respects the option `getOption("OutDec")` for the ‘decimal mark’ in general, `decimal.mark` takes precedence over that option. Similarly, `scientific` takes precedence over `getOption("scipen")`.

Value

An object of similar structure to `x` containing character representations of the elements of the first argument `x` in a common format, and in the current locale’s encoding.

For character, numeric, complex or factor `x`, `dims` and `dimnames` are preserved on matrices/arrays and names on vectors: no other attributes are copied.

If `x` is a list, the result is a character vector obtained by applying `format(x, ...)` (instead of `format.default(x, ...)` in R <= 4.5.z) to each element of the list (after `unlisting` elements which are themselves lists), and then collapsing the result for each element with `paste0(collapse = ", ")`. The defaults in this case are `trim = TRUE`, `justify = "none"` since one does not usually want alignment in the collapsed strings.

See Also

`format.info` indicates how an atomic vector would be formatted.

`formatC`, `paste`, `as.character`, `sprintf`, `print`, `prettyNum`, `toString`, `encodeString`.

Examples

```
format(1:10)
format(1:10, trim = TRUE)

zz <- data.frame("(row names)"= c("aaaaa", "b"), check.names = FALSE)
format(zz)
format(zz, justify = "left")

## use of nsmall
format(13.7)
format(13.7, nsmall = 3)
format(c(6.0, 13.1), digits = 2)
format(c(6.0, 13.1), digits = 2, nsmall = 1)

## use of scientific
format(2^31-1)
format(2^31-1, scientific = TRUE)
## scientific = numeric scipen (= {sci}entific notation {pen}alty) :
x <- c(1e5, 1000, 10, 0.1, .001, .123)
t(sapply(setNames(,-4:1),
          \(sci) sapply(x, format, scientific=sci)))

## a list
z <- list(a = letters[1:3], b = (-pi+0i)^((-2:2)/2), c = c(1,10,100,1000),
          d = c("a", "longer", "character", "string"),
          q = quote( a + b ), e = expression(1+x))
## can you find the "2" small differences?
(f1 <- format(z, digits = 2))
(f2 <- format(z, digits = 2, justify = "left", trim = FALSE))
f1 == f2 ## 2 FALSE, 4 TRUE

## A "minimal" format() for S4 objects without their own format() method:
cc <- methods::getClassDef("standardGeneric")
format(cc) ## "<S4 class .....>"
```

format.info

format(.) Information

Description

Information is returned on how `format(x, digits, nsmall)` would be formatted.

Usage

```
format.info(x, digits = NULL, nsmall = 0)
```

Arguments

<code>x</code>	an atomic vector; a potential argument of <code>format(x, ...)</code> .
<code>digits</code>	how many significant digits are to be used for numeric and complex <code>x</code> . The default, <code>NULL</code> , uses <code>getOption("digits")</code> .
<code>nsmall</code>	(see <code>format(..., nsmall)</code>).

Value

An *integer vector* of length 1, 3 or 6, say *r*.

For logical, integer and character vectors a single element, the width which would be used by `format` if `width = NULL`.

For numeric vectors:

<code>r[1]</code>	width (in characters) used by <code>format(x)</code>
<code>r[2]</code>	number of digits after decimal point.
<code>r[3]</code>	in <code>0:2</code> ; if ≥ 1 , <i>exponential</i> representation would be used, with exponent length of <code>r[3]+1</code> .

For a complex vector the first three elements refer to the real parts, and there are three further elements corresponding to the imaginary parts.

See Also

`format` (notably about `digits >= 16`), `formatC`.

Examples

```
dd <- options("digits") ; options(digits = 7) #-- for the following
format.info(123)      # 3 0 0
format.info(pi)       # 8 6 0
format.info(1e8)      # 5 0 1 - exponential "1e+08"
format.info(1e222)    # 6 0 2 - exponential "1e+222"

x <- pi*10^c(-10,-2,0:2,8,20)
names(x) <- formatC(x, width = 1, digits = 3, format = "g")
cbind(sapply(x, format))
t(sapply(x, format.info))

## using at least 8 digits right of "."
t(sapply(x, format.info, nsmall = 8))

# Reset old options:
options(dd)
```

format.pval

Format P Values

Description

`format.pval` is intended for formatting p-values.

Usage

```
format.pval(pv, digits = max(1, getOption("digits") - 2),
            eps = .Machine$double.eps, na.form = "NA", ...)
```

Arguments

<code>pv</code>	a numeric vector.
<code>digits</code>	how many significant digits are to be used.
<code>eps</code>	a numerical tolerance: see ‘Details’.
<code>na.form</code>	character representation of NAs.
<code>...</code>	further arguments to be passed to <code>format</code> such as <code>nsmall</code> .

Details

`format.pval` is mainly an auxiliary function for `print.summary.lm` etc., and does separate formatting for fixed, floating point and very small values; those less than `eps` are formatted as "`<[eps]`" (where ‘`[eps]`’ stands for `format(eps, digits)`).

Value

A character vector.

Examples

```
format.pval(c(stats::runif(5), pi^-100, NA))
format.pval(c(0.1, 0.0001, 1e-27))
```

formatC

*Formatting Using C-style Formats***Description**

`formatC()` formats numbers individually and flexibly using C style format specifications.

`prettyNum()` is used for “prettifying” (possibly formatted) numbers, also in `format.default`.

`.format.zeros(x)`, an auxiliary function of `prettyNum()`, re-formats the zeros in a vector `x` of formatted numbers.

Usage

```
formatC(x, digits = NULL, width = NULL,
        format = NULL, flag = "", mode = NULL,
        big.mark = "", big.interval = 3L,
        small.mark = "", small.interval = 5L,
        decimal.mark = getOption("OutDec"),
        preserve.width = "individual",
        zero.print = NULL, replace.zero = TRUE,
        drop0trailing = FALSE)

prettyNum(x, big.mark = "", big.interval = 3L,
          small.mark = "", small.interval = 5L,
          decimal.mark = getOption("OutDec"), input.d.mark = decimal.mark,
          preserve.width = c("common", "individual", "none"),
          zero.print = NULL, replace.zero = FALSE,
```

```

drop0trailing = FALSE, is.cmplx = NA,
...)

.format.zeros(x, zero.print, nx = suppressWarnings(as.numeric(x)),
  replace = FALSE, warn.non.fitting = TRUE)

```

Arguments

- x** an atomic numerical or character object, possibly `complex` only for `prettyNum()`, typically a vector of real numbers. Any class is discarded, with a warning.
- digits** the desired number of digits after the decimal point (`format = "f"`) or *significant* digits (`format = "g"`, `"e"` or `"fg"`).
Default: 2 for integer, 4 for real numbers. If less than 0, the C default of 6 digits is used. If specified as more than 50, 50 will be used with a warning unless `format = "f"` where it is limited to typically 324. (Not more than 15–21 digits need be accurate, depending on the OS and compiler used. This limit is just a precaution against segfaults in the underlying C runtime.)
- width** the total field width; if both `digits` and `width` are unspecified, `width` defaults to 1, otherwise to `digits + 1`. `width = 0` will use `width = digits`, `width < 0` means left justify the number in this field (equivalent to `flag = "-"`). If necessary, the result will have more characters than `width`. For character data this is interpreted in characters (not bytes nor display width).
- format** equal to `"d"` (for integers), `"f"`, `"e"`, `"E"`, `"g"`, `"G"`, `"fg"` (for reals), or `"s"` (for strings). Default is `"d"` for integers, `"g"` for reals.
`"f"` gives numbers in the usual `xxx.xxx` format; `"e"` and `"E"` give `n.ddde+nn` or `n.dddE+nn` (scientific format); `"g"` and `"G"` put `x[i]` into scientific format only if it saves space to do so *and* drop trailing zeros and decimal point - unless `flag` contains `"#"` which keeps trailing zeros for the `"g"`, `"G"` formats.
`"fg"` (our own hybrid format) uses fixed format as `"f"`, but `digits` as the minimum number of *significant* digits. This can lead to quite long result strings, see examples below. Note that unlike `signif` this prints large numbers with more significant digits than `digits`. Trailing zeros are *dropped* in this format, unless `flag` contains `"#"`.
- flag** for `formatC`, a character string giving a format modifier as in Kernighan and Ritchie (1988, page 243) or the C+99 standard.
`"0"` pads leading zeros;
`"-"` does left adjustment,
`"+"` ensures a sign in all cases, i.e., `"+"` for positive numbers ,
`" "` if the first character is not a sign, the space character `" "` will be used instead.
`"#"` specifies “an alternative output form”, specifically depending on `format`.
`"' "` on some platform–locale combination, activates “thousands’ grouping” for decimal conversion,
`"I"` in some versions of ‘glibc’ allow for integer conversion to use the locale’s alternative output digits, if any.

There can be more than one of these flags, in any order. Other characters used to have no effect for character formatting, but signal an error since R 3.4.0.

mode	"double" (or "real"), "integer" or "character". Default: Determined from the storage mode of x.
big.mark	character; if not empty used as mark between every big.interval decimals <i>before</i> (hence big) the decimal point.
big.interval	see big.mark above; defaults to 3.
small.mark	character; if not empty used as mark between every small.interval decimals <i>after</i> (hence small) the decimal point.
small.interval	see small.mark above; defaults to 5.
decimal.mark	the character to be used to indicate the numeric decimal point.
input.d.mark	if x is <code>character</code> , the character known to have been used as the numeric decimal point in x.
preserve.width	string specifying if the string widths should be preserved where possible in those cases where marks (big.mark or small.mark) are added. "common", the default, corresponds to <code>format</code> -like behavior whereas "individual" is the default in <code>formatC()</code> . Value can be abbreviated.
zero.print	logical, character string or NULL specifying if and how <i>zeros</i> should be formatted specially. Useful for pretty printing 'sparse' objects.
replace.zero, replace	logical; if zero.print is a character string, indicates if the exact zero entries in x should be simply replaced by zero.print. Otherwise, depending on the widths of the respective strings, the (formatted) zeroes are <i>partly</i> replaced by zero.print and then padded with " " to the right were applicable. In that case (false <code>replace[.zero]</code>), if the zero.print string does not fit, a warning is produced (if <code>warn.non.fitting</code> is true). This works via <code>prettyNum()</code> , which calls <code>.format.zeros(*, replace=replace.zero)</code> three times in this case, see the 'Details'.
warn.non.fitting	logical; if it is true, <code>replace[.zero]</code> is false and the zero.print string does not fit, a <code>warning</code> is signalled.
drop0trailing	logical, indicating if trailing zeros, i.e., "0" <i>after</i> the decimal mark, should be removed; also drops "e+00" in exponential formats. This is simply passed to <code>prettyNum()</code> , see the 'Details'.
is.cmplx	optional logical, to be used when x is "character" to indicate if it stems from <code>complex</code> vector or not. By default (NA), x is checked to 'look like' complex.
...	arguments passed to <code>format</code> .
nx	numeric vector of the same length as x, typically the numbers of which the character vector x is the pre-format.

Details

For numbers, `formatC()` calls `prettyNum()` when needed which itself calls `.format.zeros(*, replace=replace.zero)`. ("when needed": when `zero.print` is not NULL, `drop0trailing` is true, or one of `big.mark`, `small.mark`, or `decimal.mark` is not at default.)

If you set `format` it overrides the setting of `mode`, so `formatC(123.45, mode = "double", format = "d")` gives 123.

The rendering of scientific format is platform-dependent: some systems use `n.ddde+nnn` or `n.ddden` rather than `n.ddde+nn`.

`formatC` does not necessarily align the numbers on the decimal point, so `formatC(c(6.11, 13.1), digits = 2, format = "fg")` gives `c("6.1", " 13")`. If you want common formatting for several numbers, use `format`.

`prettyNum` is the utility function for prettifying `x`. `x` can be complex (or `format(<complex>)`), here. If `x` is not a character, `format(x[i], ...)` is applied to each element, and then it is left unchanged if all the other arguments are at their defaults. Use the `input.d.mark` argument for `prettyNum(x)` when `x` is a character vector not resulting from something like `format(<number>)` with a period as decimal mark.

Because `gsub` is used to insert the `big.mark` and `small.mark`, special characters need escaping. In particular, to insert a single backslash, use `"\\\\\\`.

The C doubles used for R numerical vectors have signed zeros, which `formatC` may output as `-0`, `-0.000 ...`.

There is a warning if `big.mark` and `decimal.mark` are the same: that would be confusing to those reading the output.

Value

A character object of same size and attributes as `x` (after discarding any class), in the current locale's encoding.

Unlike `format`, each number is formatted individually. Looping over each element of `x`, the C function `sprintf(...)` is called for numeric inputs (inside the C function `str_signif`).

`formatC`: for character `x`, do simple (left or right) padding with white space.

Note

The default for `decimal.mark` in `formatC()` was changed in R 3.2.0: for use within `print` methods in packages which might be used with earlier versions: use `decimal.mark = getOption("OutDec")` explicitly.

Author(s)

`formatC` was originally written by Bill Dunlap for S-PLUS, later much improved by Martin Maechler.

It was first adapted for R by Friedrich Leisch and since much improved by the R Core team.

stopifnot(pnv == "1+1i", pnv == format(zv),
          pnv == prettyNum(zv, drop0trailing = TRUE))
## more digits change the picture:
options(digits = 8)
head(fv <- format(zv), 3)
prettyNum(fv)
prettyNum(fv, drop0trailing = TRUE) # a bit nicer
options(op)

## The ' flag :
doLC <- FALSE # <= R warns, so change to TRUE manually if you want see the effect
if(doLC) {
  oldLC <- Sys.getlocale("LC_NUMERIC")
  Sys.setlocale("LC_NUMERIC", "de_CH.UTF-8")
}
formatC(1.234 + 10^(0:4), format = "fg", width = 11, flag = "'")
## --> ..... "      1'001" "      10'001"   on supported platforms
if(doLC) ## revert, typically to "C" :
  Sys.setlocale("LC_NUMERIC", oldLC)

```

formatDL

*Format Description Lists***Description**

Format vectors of items and their descriptions as 2-column tables or LaTeX-style description lists.

Usage

```

formatDL(x, y, style = c("table", "list"),
         width = 0.9 * getOption("width"), indent = NULL)

```

Arguments

<code>x</code>	a vector giving the items to be described, or a list of length 2 or a matrix with 2 columns giving both items and descriptions.
<code>y</code>	a vector of the same length as <code>x</code> with the corresponding descriptions. Only used if <code>x</code> does not already give the descriptions.
<code>style</code>	a character string specifying the rendering style of the description information. Can be abbreviated. If "table", a two-column table with items and descriptions as columns is produced (similar to Texinfo's <code>@table</code> environment). If "list", a LaTeX-style tagged description list is obtained.
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.
<code>indent</code>	a positive integer specifying the indentation of the second column in table style, and the indentation of continuation lines in list style. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> for table style and <code>width/9</code> for list style.

Details

After extracting the vectors of items and corresponding descriptions from the arguments, both are coerced to character vectors.

In table style, items with more than `indent - 3` characters are displayed on a line of their own.

Value

a character vector with the formatted entries.

Examples

```
## Provide a nice summary of the numerical characteristics of the
## machine R is running on:
writeLines(formatDL(unlist(.Machine)))
## Inspect Sys.getenv() results in "list" style (by default, these are
## printed in "table" style):
writeLines(formatDL(Sys.getenv(), style = "list"))
```

function

*Function Definition***Description**

These functions provide the base mechanisms for defining new functions in the R language.

Usage

```
function( arglist ) expr
\ ( arglist ) expr
return(value)
```

Arguments

<code>arglist</code>	empty or one or more (comma-separated) ‘name’ or ‘name = expression’ terms and/or the special token <code>...</code>
<code>expr</code>	an expression.
<code>value</code>	an expression.

Details

The names in an argument list can be back-quoted non-standard names (see ‘[backquote](#)’).

If `value` is missing, `NULL` is returned. If it is a single expression, the value of the evaluated expression is returned. (The expression is evaluated as soon as `return` is called, in the evaluation frame of the function and before any `on.exit` expression is evaluated.)

If the end of a function is reached without calling `return`, the value of the last evaluated expression is returned.

The shorthand form `\(x) x + 1` is parsed as `function(x) x + 1`. It may be helpful in making code containing simple function expressions more readable.

Technical details

This type of function is not the only type in R: they are called *closures* (a name with origins in LISP) to distinguish them from [primitive](#) functions.

A closure has three components, its [formals](#) (its argument list), its [body](#) (`expr` in the ‘Usage’ section) and its [environment](#) which provides the enclosure of the evaluation frame when the closure is used.

There is an optional further component if the closure has been byte-compiled. This is not normally user-visible, but is indicated when functions are printed.

See Also

[args](#).

[formals](#), [body](#) and [environment](#) for accessing the component parts of a function.

[debug](#) for debugging; using [invisible](#) inside `return(. )` for returning *invisibly*.

Examples

```
norm <- function(x) sqrt(x**x)
norm(1:4)

## An anonymous function:
(function(x, y){ z <- x^2 + y^2; x+y+z })(0:7, 1)
```

funprog

Common Higher-Order Functions in Functional Programming Languages

Description

`Reduce` uses a binary function to successively combine the elements of a given vector and a possibly given initial value.

`Filter` extracts the elements of a vector for which a predicate (logical) function gives true.

`Find` **and** `Position` give the first or last such element and its position in the vector, respectively.

`Map` applies a function to the corresponding elements of given vectors.

`Negate` creates the negation of a given function.

Usage

```
Reduce(f, x, init, right = FALSE, accumulate = FALSE, simplify = TRUE)
Filter(f, x)
Find(f, x, right = FALSE, nomatch = NULL)
Map(f, ...)
Negate(f)
Position(f, x, right = FALSE, nomatch = NA_integer_)
```

Arguments

<code>f</code>	a function of the appropriate arity (binary for <code>Reduce</code> , unary for <code>Filter</code> , <code>Find</code> and <code>Position</code> , k -ary for <code>Map</code> if this is called with k arguments). An arbitrary predicate function for <code>Negate</code> .
<code>x</code>	a vector.
<code>init</code>	an R object of the same kind as the elements of <code>x</code> .
<code>right</code>	a logical indicating whether to proceed from left to right (default) or from right to left.

<code>accumulate</code>	a logical indicating whether the successive reduce combinations should be accumulated. By default, only the final combination is used.
<code>simplify</code>	a logical indicating whether accumulated results should be simplified (by unlisting) in case they all are length one.
<code>nomatch</code>	the value to be returned in the case when “no match” (no element satisfying the predicate) is found.
<code>...</code>	vectors to which the function is <code>Map()</code> ped, and other arguments of <code>mapply</code> passed to it, e.g., <code>MoreArgs</code> .

Details

If `init` is given, `Reduce` logically adds it to the start (when proceeding left to right) or the end of `x`, respectively. If this possibly augmented vector v has $n > 1$ elements, `Reduce` successively applies f to the elements of v from left to right or right to left, respectively. I.e., a left reduce computes $l_1 = f(v_1, v_2)$, $l_2 = f(l_1, v_3)$, etc., and returns $l_{n-1} = f(l_{n-2}, v_n)$, and a right reduce does $r_{n-1} = f(v_{n-1}, v_n)$, $r_{n-2} = f(v_{n-2}, r_{n-1})$ and returns $r_1 = f(v_1, r_2)$. (E.g., if v is the sequence (2, 3, 4) and f is division, left and right reduce give $(2/3)/4 = 1/6$ and $2/(3/4) = 8/3$, respectively.) If v has only a single element, this is returned; if there are no elements, `NULL` is returned. Thus, it is ensured that f is always called with 2 arguments.

The current implementation is non-recursive to ensure stability and scalability.

`Reduce` is patterned after Common Lisp’s `reduce`. A reduce is also known as a fold (e.g., in Haskell) or an accumulate (e.g., in the C++ Standard Template Library). The accumulative version corresponds to Haskell’s scan functions.

`Filter` applies the unary predicate function f to each element of `x`, coercing to logical if necessary, and returns the subset of `x` for which this gives true. Note that possible NA values are currently always taken as false; control over NA handling may be added in the future. `Filter` corresponds to `filter` in Haskell or ‘`remove-if-not`’ in Common Lisp.

`Find` and `Position` are patterned after Common Lisp’s ‘`find-if`’ and ‘`position-if`’, respectively. If there is an element for which the predicate function gives true, then the first or last such element or its position is returned depending on whether `right` is false (default) or true, respectively. If there is no such element, the value specified by `nomatch` is returned. The current implementation is not optimized for performance.

`Map` is a simple wrapper to `mapply` which does not attempt to simplify the result, similar to Common Lisp’s `mapcar` (with arguments being recycled, however). Future versions may allow some control of the result type.

`Negate` corresponds to Common Lisp’s `complement`. Given a (predicate) function f , it creates a function which returns the logical negation of what f returns.

See Also

Function `clusterMap` and `mcmapply` (not Windows) in package **parallel** provide parallel versions of `Map`.

Examples

```
## A general-purpose adder:
add <- function(x) Reduce(`+`, x)
add(list(1, 2, 3))
## Like sum(), but can also used for adding matrices etc., as it will
## use the appropriate '+' method in each reduction step.
## More generally, many generics meant to work on arbitrarily many
```

```

## arguments can be defined via reduction:
FOO <- function(...) Reduce(FOO2, list(...))
FOO2 <- function(x, y) UseMethod("FOO2")
## FOO() methods can then be provided via FOO2() methods.

## A general-purpose cumulative adder:
cadd <- function(x) Reduce(`+`, x, accumulate = TRUE)
cadd(seq_len(7))

## A simple function to compute continued fractions:
cfrac <- function(x) Reduce(function(u, v) u + 1 / v, x, right = TRUE)
## Continued fraction approximation for pi:
cfrac(c(3, 7, 15, 1, 292))
## Continued fraction approximation for Euler's number (e):
cfrac(c(2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8))

## Map() now recycles similar to basic Ops:
Map(`+`, 1, 1 : 3) ; 1 + 1:3
Map(`+`, numeric(), 1 : 3) ; numeric() + 1:3

## Iterative function application:
Funcall <- function(f, ...) f(...)
## Compute log(exp(acos(cos(0))))
Reduce(Funcall, list(log, exp, acos, cos), 0, right = TRUE)
## n-fold iterate of a function, functional style:
Iterate <- function(f, n = 1)
  function(x) Reduce(Funcall, rep.int(list(f), n), x, right = TRUE)
## Continued fraction approximation to the golden ratio:
Iterate(function(x) 1 + 1 / x, 30)(1)
## which is the same as
cfrac(rep.int(1, 31))
## Computing square root approximations for x as fixed points of the
## function t |> (t + x / t) / 2, as a function of the initial value:
asqrt <- function(x, n) Iterate(function(t) (t + x / t) / 2, n)
asqrt(2, 30)(10) # Starting from a positive value => +sqrt(2)
asqrt(2, 30)(-1) # Starting from a negative value => -sqrt(2)

## A list of all functions in the base environment:
funs <- Filter(is.function, sapply(ls(baseenv()), get, baseenv()))
## Functions in base with more than 10 arguments:
names(Filter(function(f) length(formals(f)) > 10, funs))
## Number of functions in base with a '...' argument:
length(Filter(function(f)
  any(names(formals(f)) %in% "..."),
  funs))

## Find all objects in the base environment which are *not* functions:
Filter(Negate(is.function), sapply(ls(baseenv()), get, baseenv()))

```

Description

A call of `gc` causes a garbage collection to take place. `gcinfo` sets a flag so that automatic collection is either silent (`verbose = FALSE`) or prints memory usage statistics (`verbose =`

TRUE).

Usage

```
gc(verbose = getOption("verbose"), reset = FALSE, full = TRUE)
gcinfo(verbose)
```

Arguments

<code>verbose</code>	logical; if TRUE, the garbage collection prints statistics about cons cells and the space allocated for vectors.
<code>reset</code>	logical; if TRUE the values for maximum space used are reset to the current values.
<code>full</code>	logical; if TRUE a full collection is performed; otherwise only more recently allocated objects may be collected.

Details

A call of `gc` causes a garbage collection to take place. This will also take place automatically without user intervention, and the primary purpose of calling `gc` is for the report on memory usage. For an accurate report `full = TRUE` should be used.

It can be useful to call `gc` after a large object has been removed, as this may prompt R to return memory to the operating system.

R allocates space for vectors in multiples of 8 bytes: hence the report of "Vcells", a relic of an earlier allocator (that used a vector heap).

When `gcinfo(TRUE)` is in force, messages are sent to the message connection at each garbage collection of the form

```
Garbage collection 12 = 10+0+2 (level 0) ...
6.4 Mbytes of cons cells used (58%)
2.0 Mbytes of vectors used (32%)
```

Here the last two lines give the current memory usage rounded up to the next 0.1Mb and as a percentage of the current trigger value. The first line gives a breakdown of the number of garbage collections at various levels (for an explanation see *R Internals*).

Value

`gc` returns a matrix with rows "Ncells" (*cons cells*), usually 28 bytes each on 32-bit systems and 56 bytes on 64-bit systems, and "Vcells" (*vector cells*, 8 bytes each), and columns "used" and "gc trigger", each also interpreted in megabytes (rounded up to the next 0.1Mb).

If maxima have been set for either "Ncells" or "Vcells", a fifth column is printed giving the current limits in Mb (with NA denoting no limit).

The final two columns show the maximum space used since the last call to `gc(reset = TRUE)` (or since R started).

`gcinfo` returns the previous value of the flag.

See Also

[Memory](#) on R's memory management, and [gctorture](#) if you are an R developer.

[gc.time\(\)](#) reports *time* used for garbage collection.

[reg.finalizer](#) for actions to happen at garbage collection.

Examples

```
gc() #- do it now
gcinfo(TRUE) #-- in the future, show when R does it
##          vvvvvv use larger to *show* something
x <- integer(100000); for(i in 1:18) x <- c(x, i)
gcinfo(verbose = FALSE) #-- don't show it anymore

gc(TRUE)

gc(reset = TRUE)
```

gc.time

Report Time Spent in Garbage Collection

Description

This function reports the time spent in garbage collection so far in the R session while GC timing was enabled.

Usage

```
gc.time(on = TRUE)
```

Arguments

`on` logical; if TRUE, GC timing is enabled.

Details

Due to timer resolution this may be under-estimate.

This is a [primitive](#).

Value

A numerical vector of length 5 giving the user CPU time, the system CPU time, the elapsed time and children's user and system CPU times (normally both zero), of time spent doing garbage collection whilst GC timing was enabled.

Times of child processes are not available on Windows and will always be given as NA.

See Also

[gc](#), [proc.time](#) for the timings for the session.

Examples

```
gc.time()
```

gctorture	<i>Torture Garbage Collector</i>
-----------	----------------------------------

Description

Provokes garbage collection on (nearly) every memory allocation. Intended to ferret out memory protection bugs. Also makes R run *very* slowly, unfortunately.

Usage

```
gctorture(on = TRUE)
gctorture2(step, wait = step, inhibit_release = FALSE)
```

Arguments

on	logical; turning it on/off.
step	integer; run GC every step allocations; step = 0 turns the GC torture off.
wait	integer; number of allocations to wait before starting GC torture.
inhibit_release	logical; do not release free objects for re-use: use with caution.

Details

Calling `gctorture(TRUE)` instructs the memory manager to force a full GC on every allocation. `gctorture2` provides a more refined interface that allows the start of the GC torture to be deferred and also gives the option of running a GC only every `step` allocations.

The third argument to `gctorture2` is only used if R has been configured with a strict write barrier enabled. When this is the case all garbage collections are full collections, and the memory manager marks free nodes and enables checks in many situations that signal an error when a free node is used. This can help greatly in isolating unprotected values in C code. It does not detect the case where a node becomes free and is reallocated. The `inhibit_release` argument can be used to prevent such reallocation. This will cause memory to grow and should be used with caution and in conjunction with operating system facilities to monitor and limit process memory use.

`gctorture2` can also be invoked via environment variables at the start of the R session. `R_GCTORTURE` corresponds to the `step` argument, `R_GCTORTURE_WAIT` to `wait`, and `R_GCTORTURE_INHIBIT_RELEASE` to `inhibit_release`.

Value

Previous value of first argument.

Peter Dalgaard and Luke Tierney

get

*Return the Value of a Named Object***Description**

Search by name for an object (`get`) or zero or more objects (`mget`).

Usage

```
get(x, pos = -1, envir = as.environment(pos), mode = "any",
    inherits = TRUE)

mget(x, envir = as.environment(pos), mode = "any", ifnotfound,
     inherits = FALSE, pos = -1)

dynGet(x, ifnotfound = , minframe = 1L, inherits = FALSE)
```

Arguments

<code>x</code>	For <code>get</code> , an object name (given as a character string or a symbol). For <code>mget</code> , a character vector of object names.
<code>pos, envir</code>	where to look for the object (see ‘Details’); if omitted search as if the name of the object appeared unquoted in an expression.
<code>mode</code>	the mode or type of object sought: see the ‘Details’ section.
<code>inherits</code>	should the enclosing frames of the environment be searched?
<code>ifnotfound</code>	For <code>mget</code> , a list of values to be used if the item is not found: it will be coerced to a list if necessary. For <code>dynGet</code> any R object, e.g., a call to <code>stop()</code> .
<code>minframe</code>	integer specifying the minimal frame number to look into.

Details

The `pos` argument can specify the environment in which to look for the object in any of several ways: as a positive integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using `sys.frame` to access the currently active function calls). The default of `-1` indicates the current environment of the call to `get`. The `envir` argument is an alternative way to specify an environment.

These functions look to see if each of the name(s) `x` have a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See [environment](#) and *The R Language Definition* for details about the structure of environments and their enclosures.

If `mode` is specified then only objects of that type are sought. `mode` here is a mixture of the meanings of `typeof` and `mode`: "function" covers primitive functions and operators, "numeric", "integer" and "double" all refer to any numeric type, "symbol" and "name" are equivalent *but* "language" must be used (and not "call" or "("). Currently, `mode = "S4"` and `mode = "object"` are equivalent.

For `mget`, the values of `mode` and `ifnotfound` can be either the same length as `x` or of length 1. The argument `ifnotfound` must be a list containing either the value to use if the requested

item is not found or a function of one argument which will be called if the item is not found, with argument the name of the item being requested.

`dynGet()` is somewhat experimental and to be used *inside* another function. It looks for an object in the callers, i.e., the `sys.frame()`s of the function. Use with caution.

Value

For `get`, the object found. If no object is found an error results. If the object is the internal missing argument (aka `R_MissingArg` in C), a *classed* error, class `"getMissingError"` is signalled.

For `mget`, a named list of objects (found or specified *via* `ifnotfound`).

Note

The reverse (or “inverse”) of `a <- get(nam)` is `assign(nam, a)`, assigning `a` to name `nam`. `inherits = TRUE` is the default for `get` in R but not for S where it had a different meaning.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`exists` for checking whether an object exists; `get0` for an efficient way of both checking existence and getting an object.

`assign`, the inverse of `get()`, see above.

Use `getAnywhere` for searching for an object anywhere, including in other namespaces, and `getFromNamespace` to find an object in a specific namespace.

Examples

```
get("%o%")

## test mget
e1 <- new.env()
mget(letters, e1, ifnotfound = as.list(LETTERS))

## very low-level: get()ing the "missing argument", e.g., inside browser()
ls.str(E <- environment((\ (m) \(){}))()) # m : <missing>
str(E$m) # (empty) symbol
ee <- tryCatch(get("m", E), error = function(e) e)
str(ee)
ee
stopifnot(exprs = {
  inherits(ee, "missingArgError") # and
  inherits(ee, "getMissingError")
  ##
  inherits(tryCatch(get0("m", E), error=identity), "getMissingError")
  is.symbol(E$m) # => valid argument to get(), and *also* gets 'missing arg':
  inherits(tryCatch(get ( E$m ) , error=identity), "getMissingError")
})
```

getDLLRegisteredRoutines

Reflectance Information for C/Fortran routines in a DLL

Description

This function allows us to query the set of routines in a DLL that are registered with R to enhance dynamic lookup, error handling when calling native routines, and potentially security in the future. This function provides a description of each of the registered routines in the DLL for the different interfaces, i.e. `.C`, `.Call`, `.Fortran` and `.External`.

Usage

```
getDLLRegisteredRoutines(dll, addNames = TRUE)
```

Arguments

dll	a character string or <code>DLLInfo</code> object. The character string specifies the file name of the DLL of interest, and is given without the file name extension (e.g., the <code>'dll'</code> or <code>'so'</code>) and with no directory/path information. So a file <code>'MyPackage/libs/MyPackage.so'</code> would be specified as <code>'MyPackage'</code>. The <code>DLLInfo</code> objects can be obtained directly in calls to <code>dyn.load</code> and <code>library.dynam</code>, or can be found after the DLL has been loaded using <code>getLoadedDLLs</code>, which returns a list of <code>DLLInfo</code> objects (index-able by DLL file name). The <code>DLLInfo</code> approach avoids any ambiguities related to two DLLs having the same name but corresponding to files in different directories.
addNames	a logical value. If this is <code>TRUE</code>, the elements of the returned lists are named using the names of the routines (as seen by R via registration or raw name). If <code>FALSE</code>, these names are not computed and assigned to the lists. As a result, the call should be quicker. The name information is also available in the <code>NativeSymbolInfo</code> objects in the lists.

Details

This takes the registration information after it has been registered and processed by the R internals. In other words, it uses the extended information.

There is a `print` method for the class, which prints only the types which have registered routines.

Value

A list of class `"DLLRegisteredRoutines"` with four elements corresponding to the routines registered for the `.C`, `.Call`, `.Fortran` and `.External` interfaces. Each is a list (of class `"NativeRoutineList"`) with as many elements as there were routines registered for that interface.

Each element identifies a routine and is an object of class `"NativeSymbolInfo"`. An object of this class has the following fields:

name	the registered name of the routine (not necessarily the name in the C code).
------	--

address	the memory address of the routine as resolved in the loaded DLL. This may be NULL if the symbol has not yet been resolved.
dll	an object of class <code>DLLInfo</code> describing the DLL. This is same for all elements returned.
numParameters	the number of arguments the native routine is to be called with.

See Also

[getLoadedDLLs](#), [getNativeSymbolInfo](#) for information on the entry points listed.

Examples

```
dlls <- getLoadedDLLs()
getDLLRegisteredRoutines(dlls[["base"]])

getDLLRegisteredRoutines("stats")
```

getLoadedDLLs

Get DLLs Loaded in Current Session

Description

This function provides a way to get a list of all the DLLs (see [dyn.load](#)) that are currently loaded in the R session.

Usage

```
getLoadedDLLs()
```

Details

This queries the internal table that manages the DLLs.

Value

An object of class `"DLLInfoList"` which is a [list](#) with an element corresponding to each DLL that is currently loaded in the session. Each element is an object of class `"DLLInfo"` which has the following entries.

name	the abbreviated name.
path	the fully qualified name of the loaded DLL.

dynamicLookup	a logical value indicating whether R uses only the registration information to resolve symbols or whether it searches the entire symbol table of the DLL.
handle	a reference to the C-level data structure that provides access to the contents of the DLL. This is an object of class "DLLHandle".

Note that the class `DLLInfo` has a method for `$` which can be used to resolve native symbols within that DLL. Therefore, one must access the R-level elements described above using `[[, e.g. x[["name"]] or x[["handle"]].`

Note

We are starting to use the `handle` elements in the DLL object to resolve symbols more directly in R.

```

```
getNativeSymbolInfo
```

Obtain a Description of one or more Native (C/Fortran) Symbols

Description

This finds and returns a description of one or more dynamically loaded or ‘exported’ built-in native symbols. For each name, it returns information about the name of the symbol, the library in which it is located and, if available, the number of arguments it expects and by which interface it should be called (i.e. `.Call`, `.C`, `.Fortran`, or `.External`). Additionally, it returns the address of the symbol and this can be passed to other C routines. Specifically, this provides a way to explicitly share symbols between different dynamically loaded package libraries. Also, it provides a way to query where symbols were resolved, and aids diagnosing strange behavior associated with dynamic resolution.

Usage

```
getNativeSymbolInfo(name, PACKAGE, unlist = TRUE,
                    withRegistrationInfo = FALSE)
```

Arguments

<code>name</code>	the name(s) of the native symbol(s).
<code>PACKAGE</code>	an optional argument that specifies to which DLL to restrict the search for this symbol. If this is "base", we search in the R executable itself.
<code>unlist</code>	a logical value which controls how the result is returned if the function is called with the name of a single symbol. If <code>unlist</code> is <code>TRUE</code> and the number of symbol names in <code>name</code> is one, then the <code>NativeSymbolInfo</code> object is returned. If it is <code>FALSE</code> , then a list of <code>NativeSymbolInfo</code> objects is returned. This is ignored if the number of symbols passed in <code>name</code> is more than one. To be compatible with earlier versions of this function, this defaults to <code>TRUE</code> .
<code>withRegistrationInfo</code>	a logical value indicating whether, if <code>TRUE</code> , to return information that was registered with R about the symbol and its parameter types if such information is available, or if <code>FALSE</code> to return just the address of the symbol.

Details

This uses the same mechanism for resolving symbols as is used in all the native interfaces (`.Call`, etc.). If the symbol has been explicitly registered by the DLL in which it is contained, information about the number of arguments and the interface by which it should be called will be returned. Otherwise, a generic native symbol object is returned.

Value

Generally, a list of `NativeSymbolInfo` elements whose elements can be indexed by the elements of `name` in the call. Each `NativeSymbolInfo` object is a list containing the following elements:

<code>name</code>	the name of the symbol, as given by the <code>name</code> argument.
<code>address</code>	if <code>withRegistrationInfo</code> is <code>FALSE</code> , this is the native memory address of the symbol which can be used to invoke the routine, and also to compare with other symbol addresses. This is an external pointer object and of class <code>NativeSymbol</code> . If <code>withRegistrationInfo</code> is <code>TRUE</code> and registration information is available for the symbol, then this is an object of class <code>RegisteredNativeSymbol</code> and is a reference to an internal data type that has access to the routine pointer and registration information. This too can be used in calls to <code>.Call</code> , <code>.C</code> , <code>.Fortran</code> and <code>.External</code> .
<code>dll</code>	a list containing 3 elements: name the short form of the library name which can be used as the value of the <code>PACKAGE</code> argument in the different native interface functions. path the fully qualified name of the DLL. dynamicLookup a logical value indicating whether dynamic resolution is used when looking for symbols in this library, or only registered routines can be located.

If the routine was explicitly registered by the dynamically loaded library, the list contains a fourth field

<code>numParameters</code>	the number of arguments that should be passed in a call to this routine.
----------------------------	--

Additionally, the list will have an additional class, being `CRoutine`, `CallRoutine`, `FortranRoutine` or `ExternalRoutine` corresponding to the R interface by which it should be invoked.

If any of the symbols is not found, an error is raised.

If `name` contains only one symbol name and `unlist` is `TRUE`, then the single `NativeSymbolInfo` is returned rather than the list containing that one element.

Note

The third element of the `NativeSymbolInfo` objects was renamed from `package` to `dll` in R version 3.6.0, for consistency with the names of the `NativeSymbolInfo` objects returned by `getDLLRegisteredRoutines()`.

Note

One motivation for accessing this reflectance information is to be able to pass native routines to C routines as function pointers in C. This allows us to treat native routines and R functions in a similar manner, such as when passing an R function to C code that makes callbacks to that function at different points in its computation (e.g., `nls`). Additionally, we can resolve the symbol just once and avoid resolving it repeatedly or using the internal cache.

gettext

Translate Text Messages

Description

Translation of text messages typically from calls to `stop()`, `warning()`, or `message()` happens when Native Language Support (NLS) was enabled in this build of R as it is almost always, see also the `bindtextdomain()` example.

The functions documented here are the low level building blocks used explicitly or implicitly in almost all such message producing calls and they attempt to translate character vectors or set where the translations are to be found.

Usage

```
gettext(..., domain = NULL, trim = TRUE)

ngettext(n, msg1, msg2, domain = NULL)

bindtextdomain(domain, dirname = NULL)

Sys.setLanguage(lang, unset = "en")
```

Arguments

<code>...</code>	one or more character vectors.
<code>trim</code>	logical indicating if the white space trimming in <code>gettext()</code> should happen. <code>trim = FALSE</code> may be needed for compiled code (C / C++) messages which often end with <code>'\n'</code> .
<code>domain</code>	the 'domain' for the translation, a character string, or <code>NULL</code> ; see 'Details'.
<code>n</code>	a non-negative integer.
<code>msg1</code>	the message to be used in English for <code>n = 1</code> .
<code>msg2</code>	the message to be used in English for <code>n = 0, 2, 3, ...</code>
<code>dirname</code>	the directory in which to find translated message catalogs for the domain.
<code>lang</code>	a <code>character</code> string specifying a language for which translations should be sought.
<code>unset</code>	a string, specifying the default language assumed to be current in the case <code>Sys.getenv("LANGUAGE")</code> is unset or empty.

Details

If `domain` is `NULL` (the default) in `gettext` or `ngettext`, the domain is inferred. If `gettext` or `ngettext` is called from a function in the namespace of package **pkg** including called via `stop()`, `warning()`, or `message()` from the function, or, say, evaluated as if called from that namespace, see the `evalq()` example, the domain is set to `"R-pkg"`. Otherwise there is no default domain and messages are not translated.

Setting `domain = NA` in `gettext` or `ngettext` suppresses any translation.

`" "` does not match any domain. In `gettext` or `ngettext`, `domain = " "` is effectively the same as `domain = NA`.

If the domain is found, each character string is offered for translation, and replaced by its translation into the current language if one is found.

The *language* to be used for message translation is determined by your OS default and/or the locale setting at R's startup, see `Sys.getlocale()`, and notably the `LANGUAGE` environment variable, and also `Sys.setLanguage()` here.

Conventionally the domain for R warning/error messages in package **pkg** is `"R-pkg"`, and that for C-level messages is `"pkg"`.

For `gettext`, when `trim` is true as by default, leading and trailing whitespace is ignored ("trimmed") when looking for the translation. R-level message catalogues from `xgettext2pot` contain only trimmed messages.

`ngettext` is used where the message needs to vary by a single integer. Translating such messages is subject to very specific rules for different languages: see the GNU `gettext` manual. The string

will often contain a single instance of `%d` to be used in `sprintf`. If English is used, `msg1` is returned if `n == 1` and `msg2` in all other cases.

`bindtextdomain` is typically a wrapper for the C function of the same name: your system may have a man page for it. With a non-NULL `dirname` it specifies where to look for message catalogues: with `dirname = NULL` it returns the current location. If NLS is not enabled, `bindtextdomain(*,*)` returns `NULL`. The special case `bindtextdomain(NULL)` calls C level `textdomain(textdomain(NULL))` for the purpose of flushing (i.e., emptying) the cache of already translated strings; it returns `TRUE` when NLS is enabled.

The utility `Sys.setLanguage(lang)` combines setting the `LANGUAGE` environment variable with flushing the translation cache by `bindtextdomain(NULL)`.

Value

For `gettext`, a character vector, one element per string in If translation is not enabled or no domain is found or no translation is found in that domain, the original strings are returned.

For `ngettext`, a character string.

For `bindtextdomain`, a character string giving the current base directory, or `NULL` if setting it failed.

For `Sys.setLanguage()`, the previous `LANGUAGE` setting with attribute `attr(*, "ok")`, a `logical` indicating success. Note that currently, using a non-existing language `lang` is still set and no translation will happen, without any `message`.

Warning

These functions were written assuming that environment variable `LANGUAGE` is supported by the implementation of `libintl`. This is almost universally true and (along with `gettext` et al.) became part of the 2024 POSIX specification. In 2025, however, it was still ignored by the implementation in `musl` (one of the implementations available on Alpine Linux).

See Also

`stop` and `warning` make use of `gettext` to translate messages.

`xgettext` (package `tools`) for extracting translatable strings from R source files.

Examples

```
bindtextdomain("R") # non-null if and only if NLS is enabled

for(n in 0:3)
  print(sprintf(ngettext(n, "%d variable has missing values",
                        "%d variables have missing values"),
              n))

## Not run: ## for translation, those strings should appear in R-pkg.pot as
msgid      "%d variable has missing values"
msgid_plural "%d variables have missing values"
msgstr[0] ""
msgstr[1] ""

## End(Not run)

miss <- "One only" # this line, or the next for the ngettext() below
miss <- c("one", "or", "another")
```

```

cat(ngettext(length(miss), "variable", "variables"),
    paste(sQuote(miss), collapse = ", "),
    ngettext(length(miss), "contains", "contain"), "missing values\n")

## better for translators would be to use
cat(sprintf(ngettext(length(miss),
    "variable %s contains missing values\n",
    "variables %s contain missing values\n"),
    paste(sQuote(miss), collapse = ", ")))

thisLang <- Sys.getenv("LANGUAGE", unset = NA) # so we can reset it
if(is.na(thisLang) || !nzchar(thisLang)) thisLang <- "en" # "factory" default
enT <- "empty model supplied"
Sys.setenv(LANGUAGE = "de") # may not always 'work'
gettext(enT, domain="R-stats") # "leeres Modell angegeben" (if translation works)
tget <- function() gettext(enT)
tget() # not translated as fn tget() is not from "stats" pkg/namespace
evalq(function() gettext(enT), asNamespace("stats"))() # *is* translated

## Sys.setLanguage() -- typical usage --
Sys.setLanguage("en") -> oldSet # does set LANGUAGE env.var
errMsg <- function(expr) tryCatch(expr, error=conditionMessage)
(errMsg(1 + "2") -> err)
Sys.setLanguage("fr")
errMsg(1 + "2")
Sys.setLanguage("de")
errMsg(1 + "2")
## Usually, you would reset the language to "previous" via
Sys.setLanguage(oldSet)

## A show off of translations -- platform (font etc) dependent:
## The translation languages available for "base" R in this version of R:
if(capabilities("NLS")) withAutoprint({
  langs <- list.files(bindtextdomain("R"),
    pattern = "[a-z]{2}_[A-Z]{2}|@quot)?$")
  langs
  txts <- sapply(setNames(langs),
    function(lang) { Sys.setLanguage(lang)
      gettext("incompatible dimensions", domain="R-stats") })
  cbind(txts)
  (nTrans <- length(unique(txts)))
  (not_translated <- names(txts[txts == txts[["en"]]]))
})

## Here, we reset to the *original* setting before the full example started:
if(nzchar(thisLang)) { ## reset to previous and check
  Sys.setLanguage(thisLang)
  stopifnot(identical(errMsg(1 + "2"), err))
} # else staying at 'de' ..

```

Description

`getwd` returns an absolute filepath representing the current working directory of the R process; `setwd(dir)` is used to set the working directory to `dir`.

Usage

```
getwd()  
setwd(dir)
```

Arguments

`dir` A character string: [tilde expansion](#) will be done.

Details

See [files](#) for how file paths with marked encodings are interpreted.

Value

`getwd` returns a character string or `NULL` if the working directory is not available. On Windows the path returned will use `/` as the path separator and be encoded in UTF-8. The path will not have a trailing `/` unless it is the root directory (of a drive or share on Windows).

`setwd` returns the current directory before the change, invisibly and with the same conventions as `getwd`. It will give an error if it does not succeed (including if it is not implemented).

Note

Note that the return value is said to be **an** absolute filepath: there can be more than one representation of the path to a directory and on some OSes the value returned can differ after changing directories and changing back to the same directory (for example if symbolic links have been traversed).

See Also

[list.files](#) for the *contents* of a directory.

[normalizePath](#) for a ‘canonical’ path name.

Examples

```
(WD <- getwd())  
if (!is.null(WD)) setwd(WD)
```

gl	<i>Generate Factor Levels</i>
----	-------------------------------

Description

Generate factors by specifying the pattern of their levels.

Usage

```
gl(n, k, length = n*k, labels = seq_len(n), ordered = FALSE)
```

Arguments

n	an integer giving the number of levels.
k	an integer giving the number of replications.
length	an integer giving the length of the result.
labels	an optional vector of labels for the resulting factor levels.
ordered	a logical indicating whether the result should be ordered or not.

Value

The result has levels from 1 to n with each value replicated in groups of length k out to a total length of length.

gl is modelled on the *GLIM* function of the same name.

See Also

The underlying `factor()`.

Examples

```
## First control, then treatment:
gl(2, 8, labels = c("Control", "Treat"))
## 20 alternating 1s and 2s
gl(2, 1, 20)
## alternating pairs of 1s and 2s
gl(2, 2, 20)
```

grep	<i>Pattern Matching and Replacement</i>
------	---

Description

grep, grepv, grepl, regexpr, gregexpr, regexec and gregexec search for matches to argument pattern within each element of a character vector: they differ in the format of and amount of detail in the results.

sub and gsub perform replacement of the first and all matches respectively within each element of a character vector.

Usage

```

grep(pattern, x, ignore.case = FALSE, perl = FALSE, value = FALSE,
      fixed = FALSE, useBytes = FALSE, invert = FALSE)

grepv(pattern, x, ignore.case = FALSE, perl = FALSE, value = TRUE,
      fixed = FALSE, useBytes = FALSE, invert = FALSE)

grepl(pattern, x, ignore.case = FALSE, perl = FALSE,
      fixed = FALSE, useBytes = FALSE)

sub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

gsub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

regexpr(pattern, text, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

gregexpr(pattern, text, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

regexec(pattern, text, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

gregexec(pattern, text, ignore.case = FALSE, perl = FALSE,
    fixed = FALSE, useBytes = FALSE)

```

Arguments

pattern	character string containing a regular expression (or character string for <code>fixed = TRUE</code>) to be matched in the given character vector. Coerced by as.character to a character string if possible. If a character vector of length 2 or more is supplied, the first element is used with a warning. Missing values are allowed except for <code>regexpr</code> , <code>gregexpr</code> and <code>regexec</code> .
x, text	a character vector where matches are sought, or an object which can be coerced by as.character to a character vector. Long vectors are supported.
ignore.case	logical. if <code>FALSE</code> , the pattern matching is <i>case sensitive</i> and if <code>TRUE</code> , case is ignored during matching.
perl	logical. Should Perl-compatible regexps be used?
value	logical. If <code>FALSE</code> , a vector containing the (integer) indices of the matches determined by <code>grep</code> is returned, and if <code>TRUE</code> , a vector containing the matching elements themselves is returned.
fixed	logical. If <code>TRUE</code> , pattern is a string to be matched as is. Overrides all conflicting arguments.
useBytes	logical. If <code>TRUE</code> the matching is done byte-by-byte rather than character-by-character. See ‘Details’.
invert	logical. If <code>TRUE</code> return indices or values for elements that do <i>not</i> match.
replacement	a replacement for the matched pattern in <code>sub</code> and <code>gsub</code> . Coerced to character if possible. For <code>fixed = FALSE</code> this can include backreferences <code>"\1"</code> to <code>"\9"</code>

to parenthesized subexpressions of `pattern`. For `perl = TRUE` only, it can also contain `"\U"` or `"\L"` to convert the rest of the replacement to upper or lower case and `"\E"` to end case conversion. If a character vector of length 2 or more is supplied, the first element is used with a warning. If `NA`, all elements in the result corresponding to matches will be set to `NA`.

Details

Arguments which should be character strings or character vectors are coerced to character if possible.

Each of these functions operates in one of three modes:

1. `fixed = TRUE`: use exact matching.
2. `perl = TRUE`: use Perl-style regular expressions.
3. `fixed = FALSE`, `perl = FALSE`: use POSIX 1003.2 extended regular expressions (the default).

See the help pages on [regular expression](#) for details of the different types of regular expressions.

The two `*sub` functions differ only in that `sub` replaces only the first occurrence of a `pattern` whereas `gsub` replaces all occurrences. If `replacement` contains backreferences which are not defined in `pattern` the result is undefined (but most often the backreference is taken to be `" "`).

For `regexpr`, `gregexpr`, `regexec` and `gregexec` it is an error for `pattern` to be `NA`, otherwise `NA` is permitted and gives an `NA` match.

`grep` and `grepv` only differ in the default of the `value` argument.

Both `grep` and `grepl` take missing values in `x` as not matching a non-missing `pattern`.

The main effect of `useBytes = TRUE` is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales, but for `regexpr` it changes the interpretation of the output. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes" (see [Encoding](#)).

Caseless matching does not make much sense for bytes in a multibyte locale, and you should expect it only to work for ASCII characters if `useBytes = TRUE`.

`regexpr` and `gregexpr` with `perl = TRUE` allow Python-style named captures, but not for *long vector* inputs.

Invalid inputs in the current locale are warned about up to 5 times.

Caseless matching with `perl = TRUE` for non-ASCII characters depends on the PCRE library being compiled with 'Unicode property support', which PCRE2 is by default.

Value

`grep(value = FALSE)` returns a vector of the indices of the elements of `x` that yielded a match (or not, for `invert = TRUE`). This will be an integer vector unless the input is a *long vector*, when it will be a double vector.

`grep(value = TRUE)` returns a character vector containing the selected elements of `x` (after coercion, preserving names but no other attributes).

`grepl` returns a logical vector (match or not for each element of `x`).

`sub` and `gsub` return a character vector of the same length and with the same attributes as `x` (after possible coercion to character). Elements of character vectors `x` which are not substituted will be returned unchanged (including any declared encoding if `useBytes = FALSE`). If `useBytes = FALSE` a non-ASCII substituted result will often be in UTF-8 with a marked encoding (e.g., if there

is a UTF-8 input, and in a multibyte locale unless `fixed = TRUE`). Such strings can be re-encoded by `enc2native`. If any of the inputs is marked as "bytes", elements of character vectors `x` which are substituted will be returned marked as "bytes", but the encoding flag on elements not substituted is unspecified (it may be the original or "bytes"). If none of the inputs is marked as "bytes", but `useBytes = TRUE` is given explicitly, the encoding flag is unspecified even on the substituted elements (it may be "bytes" or "unknown", possibly invalid in the current encoding). Mixed use of "bytes" and other marked encodings is discouraged, but if still desired one may use `iconv` to re-encode the result e.g. to UTF-8 with suitably substituted invalid bytes.

`regexpr` returns an integer vector of the same length as `text` giving the starting position of the first match or `-1` if there is none, with attribute `"match.length"`, an integer vector giving the length of the matched text (or `-1` for no match). The match positions and lengths are in characters unless `useBytes = TRUE` is used, when they are in bytes (as they are for ASCII-only matching; in either case an attribute `useBytes` with value `TRUE` is set on the result). If named capture is used there are further attributes `"capture.start"`, `"capture.length"` and `"capture.names"`.

`gregexpr` returns a list of the same length as `text` each element of which is of the same form as the return value for `regexpr`, except that the starting positions of every (disjoint) match are given.

`regexec` returns a list of the same length as `text` each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` a vector giving the lengths of the matches (or `-1` for no match). The interpretation of positions and length and the attributes follows `regexpr`.

`gregexec` returns the same as `regexec`, except that to accommodate multiple matches per element of `text`, the integer sequences for each match are made into columns of a matrix, with one matrix per element of `text` with matches.

Where matching failed because of resource limits (especially for `perl = TRUE`) this is regarded as a non-match, usually with a warning.

Warning

The POSIX 1003.2 mode of `gsub` and `gregexpr` does not work correctly with repeated word-boundaries (e.g., `pattern = "\\b"`). Use `perl = TRUE` for such matches (but that may not work as expected with non-ASCII inputs, as the meaning of 'word' is system-dependent).

Performance considerations

If you are doing a lot of regular expression matching, including on very long strings, you will want to consider the options used. Generally `perl = TRUE` will be faster than the default regular expression engine, and `fixed = TRUE` faster still (especially when each pattern is matched only a few times).

If you are working with texts with non-ASCII characters, which can be easily turned into ASCII (e.g. by substituting fancy quotes), doing so is likely to improve performance.

If you are working in a single-byte locale (though not common since R 4.2) and have marked UTF-8 strings that are representable in that locale, convert them first as just one UTF-8 string will force all the matching to be done in Unicode, which attracts a penalty of around $3 \times$ for the default POSIX 1003.2 mode.

While `useBytes = TRUE` will improve performance further, because the strings will not be checked before matching and the actual matching will be faster, it can produce unexpected results so is best avoided. With `fixed = TRUE` and `useBytes = FALSE`, optimizations are in place that take advantage of byte-based matching working for such patterns in UTF-8. With `useBytes =`

TRUE, character ranges, wildcards, and other regular expression patterns may produce unexpected results.

PCRE-based matching by default used to put additional effort into ‘studying’ the compiled pattern when `x/text` has length 10 or more. That study may use the PCRE JIT compiler on platforms where it is available (see [pcre_config](#)). As from PCRE2 (PCRE version ≥ 10.00 as reported by `extSoftVersion`), there is no study phase, but the patterns are optimized automatically when possible, and PCRE JIT is used when enabled. The details are controlled by `options` `PCRE_study` and `PCRE_use_JIT`. (Some timing comparisons can be seen by running file ‘tests/PCRE.R’ in the R sources (and perhaps installed).) People working with PCRE and very long strings can adjust the maximum size of the JIT stack by setting environment variable `R_PCRE_JIT_STACK_MAXSIZE` before JIT is used to a value between 1 and 1000 in MB: the default is 64. When JIT is not used with PCRE version < 10.30 (that is with PCRE1 and old versions of PCRE2), it might also be wise to set the option `PCRE_limit_recursion`.

Warning

An all too common mis-usage is to pass unnamed arguments which are then matched to one or more of `ignore.case`, `perl`, `value`, `fixed`, `useBytes` and `invert`. So it is good practice to name all the arguments (especially as `x/text` is not the first argument).

Note

Aspects will be platform-dependent as well as locale-dependent: for example the implementation of character classes (except `[:digit:]` and `[:xdigit:]`). One can expect results to be consistent for ASCII inputs and when working in UTF-8 mode (when most platforms will use Unicode character tables, although those are updated frequently and subject to some degree of interpretation – is a circled capital letter alphabetic or a symbol?). However, results in 8-bit encodings can differ considerably between platforms, modes and from the UTF-8 versions.

Source

The C code for POSIX-style regular expression matching has changed over the years. As from R 2.10.0 (Oct 2009) the TRE library of Ville Laurikari (<https://github.com/laurikari/tre>) is used. The POSIX standard does give some room for interpretation, especially in the handling of invalid regular expressions and the collation of character ranges, so the results will have changed slightly over the years.

For Perl-style matching PCRE2 or PCRE (<https://www.pcre.org>) is used: again the results may depend (slightly) on the version of PCRE in use.

Examples

```
grep("[a-z]", letters)

txt <- c("arm", "foot", "lefroo", "bafoobar")
if(length(i <- grep("foo", txt)))
  cat("'foo' appears at least once in\n\t", txt, "\n")
i # 2 and 4
txt[i]

## Double all 'a' or 'b's; "\" must be escaped, i.e., 'doubled'
gsub("([ab])", "\\1_\\1", "abc and ABC")

txt <- c("The", "licenses", "for", "most", "software", "are",
  "designed", "to", "take", "away", "your", "freedom",
  "to", "share", "and", "change", "it.",
  "", "By", "contrast,", "the", "GNU", "General", "Public", "License",
  "is", "intended", "to", "guarantee", "your", "freedom", "to",
  "share", "and", "change", "free", "software", "--",
  "to", "make", "sure", "the", "software", "is",
  "free", "for", "all", "its", "users")
( i <- grep("[gu]", txt) ) # indices
stopifnot( txt[i] == grep("[gu]", txt, value = TRUE) )

## Note that for some implementations character ranges are
## locale-dependent (but not currently). Then [b-e] in locales such as
## en_US may include B as the collation order is aAbBcCdDe ...
(ot <- sub("[b-e]", ".", txt))
txt[ot != gsub("[b-e]", ".", txt)]#- gsub does "global" substitution
## In caseless matching, ranges include both cases:
a <- grep("[b-e]", txt, value = TRUE)
b <- grep("[b-e]", txt, ignore.case = TRUE, value = TRUE)
setdiff(b, a)

txt[gsub("g", "#", txt) !=
  gsub("g", "#", txt, ignore.case = TRUE)] # the "G" words

regexpr("en", txt)

gregexpr("e", txt)

## Using grepl() for filtering
## Find functions with argument names matching "warn":
findArgs <- function(env, pattern) {
  nms <- ls(envir = as.environment(env))
  nms <- nms[is.na(match(nms, c("F", "T")))] # <-- work around "checking hack"
```

```

aa <- sapply(nms, function(.) { o <- get(.)
  if(is.function(o)) names(formals(o)) })
iw <- sapply(aa, function(a) any(grepl(pattern, a, ignore.case=TRUE)))
aa[iw]
}
findArgs("package:base", "warn")

## trim trailing white space
str <- "Now is the time      "
sub(" +$", "", str) ## spaces only
## what is considered 'white space' depends on the locale.
sub("[:space:]+$", "", str) ## white space, POSIX-style
## what PCRE considered white space changed in version 8.34: see ?regex
sub("\\s+$", "", str, perl = TRUE) ## PCRE-style white space

## capitalizing
txt <- "a test of capitalizing"
gsub("(\\w)(\\w*)", "\\U\\1\\L\\2", txt, perl=TRUE)
gsub("\\b(\\w)", "\\U\\1", txt, perl=TRUE)

txt2 <- "useRs may fly into JFK or laGuardia"
gsub("(\\w)(\\w*)(\\w)", "\\U\\1\\E\\2\\U\\3", txt2, perl=TRUE)
sub("(\\w)(\\w*)(\\w)", "\\U\\1\\E\\2\\U\\3", txt2, perl=TRUE)

## named capture
notables <- c(" Ben Franklin and Jefferson Davis",
  "\tMillard Fillmore")
# name groups 'first' and 'last'
name.rex <- "(?<first>[[:upper:]]+[[:lower:]]+)(?<last>[[:upper:]]+[[:lower:]]+)"
(parsed <- regexpr(name.rex, notables, perl = TRUE))
gregexpr(name.rex, notables, perl = TRUE)[[2]]
parse.one <- function(res, result) {
  m <- do.call(rbind, lapply(seq_along(res), function(i) {
    if(result[i] == -1) return("")
    st <- attr(result, "capture.start")[i, ]
    substring(res[i], st, st + attr(result, "capture.length")[i, ] - 1)
  }))
  colnames(m) <- attr(result, "capture.names")
  m
}
parse.one(notables, parsed)

## Decompose a URL into its components.
## Example by LT (http://www.cs.uiowa.edu/~luke/R/regex.html).
x <- "http://stat.umn.edu:80/xyz"
m <- regexec("^(([^\:]+)://)?([^\:\/]+)(:([0-9]+))?(/.*)", x)
m
regmatches(x, m)
## Element 3 is the protocol, 4 is the host, 6 is the port, and 7
## is the path. We can use this to make a function for extracting the
## parts of a URL:
URL_parts <- function(x) {
  m <- regexec("^(([^\:]+)://)?([^\:\/]+)(:([0-9]+))?(/.*)", x)
  parts <- do.call(rbind,
    lapply(regmatches(x, m), `[`, c(3L, 4L, 6L, 7L)))
  colnames(parts) <- c("protocol", "host", "port", "path")
  parts
}

```

```

}
URL_parts(x)

## gregexec() may match multiple times within a single string.
pattern <- "[[:alpha:]]+([[:digit:]]+)"
s <- "Test: A1 BC23 DEF456"
m <- gregexec(pattern, s)
m
regmatches(s, m)

## Before gregexec() was implemented, one could emulate it by running
## regexec() on the regmatches obtained via gregexpr(). E.g.:
lapply(regmatches(s, gregexpr(pattern, s)),
       function(e) regmatches(e, regexec(pattern, e)))

```

grepRaw

*Pattern Matching for Raw Vectors***Description**

grepRaw searches for substring pattern matches within a raw vector x.

Usage

```
grepRaw(pattern, x, offset = 1L, ignore.case = FALSE,
        value = FALSE, fixed = FALSE, all = FALSE, invert = FALSE)
```

Arguments

pattern	raw vector containing a regular expression (or fixed pattern for fixed = TRUE) to be matched in the given raw vector. Coerced by charToRaw to a character string if possible.
x	a raw vector where matches are sought, or an object which can be coerced by charToRaw to a raw vector. Long vectors are not supported.
ignore.case	if FALSE, the pattern matching is <i>case sensitive</i> and if TRUE, case is ignored during matching.
offset	an integer specifying the offset from which the search should start. Must be positive. The beginning of line is defined to be at that offset so "^" will match there.
value	logical. Determines the return value: see 'Value'.
fixed	logical. If TRUE, pattern is a pattern to be matched as is.
all	logical. If TRUE all matches are returned, otherwise just the first one.
invert	logical. If TRUE return indices or values for elements that do <i>not</i> match. Ignored (with a warning) unless value = TRUE.

Details

Unlike `grep`, seeks matching patterns within the raw vector `x`. This has implications especially in the `all = TRUE` case, e.g., patterns matching empty strings are inherently infinite and thus may lead to unexpected results.

The argument `invert` is interpreted as asking to return the complement of the match, which is only meaningful for `value = TRUE`. Argument `offset` determines the start of the search, not of the complement. Note that `invert = TRUE` with `all = TRUE` will split `x` into pieces delimited by the pattern including leading and trailing empty strings (consequently the use of regular expressions with `"^"` or `"$"` in that case may lead to less intuitive results).

Some combinations of arguments such as `fixed = TRUE` with `value = TRUE` are supported but are less meaningful.

Value

`grepRaw(value = FALSE)` returns an integer vector of the offsets at which matches have occurred. If `all = FALSE` then it will be either of length zero (no match) or length one (first matching position).

`grepRaw(value = TRUE, all = FALSE)` returns a raw vector which is either empty (no match) or the matched part of `x`.

`grepRaw(value = TRUE, all = TRUE)` returns a (potentially empty) list of raw vectors corresponding to the matched parts.

Warning

An all too common mis-usage is to pass unnamed arguments which are then matched to one or more of `ignore.case`, `value`, `fixed`, `all` or `invert`. So it is good practice to name all the arguments.

Source

The TRE library of Ville Laurikari (<https://github.com/laurikari/tre/>) is used except for `fixed = TRUE`.

See Also

[regular expression](#) (aka [regexp](#)) for the details of the pattern specification.

[grep](#) for matching character vectors.

Examples

```
grepRaw("no match", "textText") # integer(0): no match
grepRaw("adf", "adadfadfdadadf") # 3 - the first match
grepRaw("adf", "adadfadfdadadf", all=TRUE, fixed=TRUE)
## [1] 3 6 13 -- three matches
```

groupGeneric

*S3 Group Generic Functions***Description**

Group generic methods can be defined for the following pre-specified groups of functions, `Math`, `Ops`, `matrixOps`, `Summary` and `Complex`. (There are no objects of these names in base R, but there are in the **methods** package.)

A method defined for an individual member of the group takes precedence over a method defined for the group as a whole.

Usage

```
## S3 methods for group generics have prototypes:
Math(x, ...)
Ops(e1, e2)
Complex(z)
Summary(..., na.rm = FALSE)
matrixOps(x, y)
```

Arguments

<code>x, y, z, e1, e2</code>	objects.
<code>...</code>	further arguments passed to methods.
<code>na.rm</code>	logical: should missing values be removed?

Details

There are five *groups* for which S3 methods can be written, namely the "Math", "Ops", "Summary", "matrixOps", and "Complex" groups. These are not R objects in base R, but methods can be supplied for them and base R contains `factor`, `data.frame` and `difftime` methods for the first three groups. (There is also a `ordered` method for Ops, `POSIXt` and `Date` methods for Math and Ops, `package_version` methods for Ops and Summary, as well as a `ts` method for Ops in package **stats**.)

1. Group "Math":

- `abs`, `sign`, `sqrt`,
 `floor`, `ceiling`, `trunc`,
 `round`, `signif`
- `exp`, `log`, `expm1`, `log1p`,
 `cos`, `sin`, `tan`,
 `cospi`, `sinpi`, `tanpi`,
 `acos`, `asin`, `atan`
 `cosh`, `sinh`, `tanh`,
 `acosh`, `asinh`, `atanh`
- `lgamma`, `gamma`, `digamma`, `trigamma`
- `cumsum`, `cumprod`, `cummax`, `cummin`

Members of this group dispatch on `x`. Most members accept only one argument, but members `log`, `round` and `signif` accept one or two arguments, and `trunc` accepts one or more.

2. Group "Ops":

- "+", "-", "*", "/", "^", "%%", "%/%"
- "&", "|", "!"
- "==", "!=", "<", "<=", ">=", ">"

This group contains both binary and unary operators (+, − and !): when a unary operator is encountered the Ops method is called with one argument and e2 is missing.

The classes of both arguments are considered in dispatching any member of this group. For each argument its vector of classes is examined to see if there is a matching specific (preferred) or Ops method. If a method is found for just one argument or the same method is found for both, it is used. If different methods are found, then the generic chooseOpsMethod() is called to pick the appropriate method. (See ?chooseOpsMethod for details). If chooseOpsMethod() does not resolve the method, then there is a warning about ‘incompatible methods’: in that case or if no method is found for either argument the internal method is used.

Note that the `data.frame` methods for the comparison ("Compare": ==, <, ...) and logic ("Logic": & | and !) operators return a logical `matrix` instead of a data frame, for convenience and back compatibility.

If the members of this group are called as functions, any argument names are removed to ensure that positional matching is always used.

3. Group "matrixOps":

- "%*%"

This group currently contains the matrix multiply `%*%` binary operator only, where at least `crossprod()` and `tcrossprod()` are meant to follow. Members of the group have the same dispatch semantics (using *both* arguments) as the Ops group.

4. Group "Summary":

- all, any
- sum, prod
- min, max
- range

Members of this group dispatch on the first argument supplied.

Note that the `data.frame` methods for the "Summary" and "Math" groups require “numeric-alike” columns x, i.e., fulfilling

```
is.numeric(x) || is.logical(x) || is.complex(x)
```

5. Group "Complex":

- Arg, Conj, Im, Mod, Re

Members of this group dispatch on z.

Note that a method will be used for one of these groups or one of its members *only* if it corresponds to a "class" attribute, as the internal code dispatches on `oldClass` and not on `class`. This is for efficiency: having to dispatch on, say, `Ops.integer` would be too slow.

The number of arguments supplied for primitive members of the "Math" group generic methods is not checked prior to dispatch.

There is no lazy evaluation of arguments for group-generic functions.

Technical Details

These functions are all primitive and [internal generic](#).

The details of method dispatch and variables such as `.Generic` are discussed in the help for [UseMethod](#). There are a few small differences:

- For the operators of group `Ops`, the object `.Method` is a length-two character vector with elements the methods selected for the left and right arguments respectively. (If no method was selected, the corresponding element is `" "`.)
- Object `.Group` records the group used for dispatch (if a specific method is used this is `" "`).

Note

Package **methods** does contain objects with these names, which it has re-used in confusing similar (but different) ways. See the help for that package.

[methods](#) for methods of non-internal generic functions.

[S4groupGeneric](#) for group generics for S4 methods.

Examples

```
require(utils)

d.fr <- data.frame(x = 1:9, y = stats::rnorm(9))
class(1 + d.fr) == "data.frame" ##-- add to d.f. ...

methods("Math")
methods("Ops")
methods("Summary")
methods("Complex") # none in base R
```

grouping

Grouping Permutation

Description

`grouping` returns a permutation which rearranges its first argument such that identical values are adjacent to each other. Also returned as attributes are the group-wise partitioning and the maximum group size.

Usage

```
grouping(...)
```

Arguments

... a sequence of numeric, character or logical vectors, all of the same length, or a classed R object.

Details

The function partially sorts the elements so that identical values are adjacent. NA values come last. This is guaranteed to be stable, so ties are preserved, and if the data are already grouped/sorted, the grouping is unchanged. This is useful for aggregation and is particularly fast for character vectors.

Under the covers, the "radix" method of [order](#) is used, and the same caveats apply, including restrictions on character encodings and lack of support for [long vectors](#) (those with 2^{31} or more elements). Real-valued numbers are slightly rounded to account for numerical imprecision.

Like [order](#), for a classed R object the grouping is based on the result of [xtfrm](#).

Value

An object of class "grouping", the representation of which should be considered experimental and subject to change. It is an integer vector with two attributes:

ends	subscripts in the result corresponding to the last member of each group
maxgrpn	the maximum group size

See Also

[order](#), [xtfrm](#).

Examples

```
(ii <- grouping(x <- c(1, 1, 3:1, 1:4, 3), y <- c(9, 9:1), z <- c(2, 1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x, y, z)[, ii]
```

gzcon

(De)compress I/O Through Connections

Description

[gzcon](#) provides a modified connection that wraps an existing connection, and decompresses reads or compresses writes through that connection. Standard [gzip](#) headers are assumed.

Usage

```
gzcon(con, level = 6, allowNonCompressed = TRUE, text = FALSE)
```

Arguments

con	a connection.
level	integer between 0 and 9, the compression level when writing.
allowNonCompressed	logical. When reading, should non-compressed input be allowed?
text	logical. Should the connection be text-oriented? This is distinct from the mode of the connection (must always be binary). If TRUE, pushBack works on the connection, otherwise readBin and friends apply.

Details

If `con` is open then the modified connection is opened. Closing the wrapper connection will also close the underlying connection.

Reading from a connection which does not supply a `gzip` magic header is equivalent to reading from the original connection if `allowNonCompressed` is true, otherwise an error.

Compressed output will contain embedded NUL bytes, and so `con` is not permitted to be a `textConnection` opened with `open = "w"`. Use a writable `rawConnection` to compress data into a variable.

The original connection becomes unusable: any object pointing to it will now refer to the modified connection. For this reason, the new connection needs to be closed explicitly.

Value

An object inheriting from class `"connection"`. This is the same connection *number* as supplied, but with a modified internal structure. It has binary mode.

See Also

`gzfile`

Examples

```
## Uncompress a data file from a URL
z <- gzcon(url("https://www.stats.ox.ac.uk/pub/datasets/csb/ch12.dat.gz"))
# read.table can only read from a text-mode connection.
raw <- textConnection(readLines(z))
close(z)
dat <- read.table(raw)
close(raw)
dat[1:4, ]

## gzfile and gzcon can inter-work.
## Of course here one would use gzfile, but file() can be replaced by
## any other connection generator.
zzfil <- tempfile(fileext = ".gz")
zz <- gzfile(zzfil, "w")
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzcon(file(zzfil, "rb")))
close(zz)
unlink(zzfil)

zzfil2 <- tempfile(fileext = ".gz")
zz <- gzcon(file(zzfil2, "wb"))
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile(zzfil2))
close(zz)
unlink(zzfil2)
```

hexmode

*Integer Numbers Displayed in Hexadecimal***Description**

Integers which are displayed in hexadecimal (short ‘hex’) format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Arithmetic works as for integers, and non-integer valued mathematical functions typically work by truncating the result to integer.

Usage

```
as.hexmode(x)

## S3 method for class 'hexmode'
as.character(x, keepStr = FALSE, ...)

## S3 method for class 'hexmode'
format(x, width = NULL, upper.case = FALSE, ...)

## S3 method for class 'hexmode'
print(x, ...)
```

Arguments

<code>x</code>	an object, for the methods inheriting from class "hexmode".
<code>keepStr</code>	a logical indicating that names and dimensions should be kept; set TRUE for back compatibility, if needed.
<code>width</code>	NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.
<code>upper.case</code>	a logical indicating whether to use upper-case letters or lower-case letters (default).
<code>...</code>	further arguments passed to or from other methods.

Details

Class "hexmode" consists of integer vectors with that class attribute, used primarily to ensure that they are printed in hex. Subsetting (`[]`) works too, as do arithmetic or other mathematical operations, albeit truncated to integer.

`as.character(x)` drops all [attributes](#) (unless when `keepStr=TRUE` where it keeps, `dim`, `dimnames` and `names` for back compatibility) and converts each entry individually, hence with no leading zeroes, whereas in `format()`, when `width = NULL` (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

`as.hexmode` can convert integers (of [type](#) "integer" or "double") and character vectors whose elements contain only 0–9, a–f, A–F (or are NA) to class "hexmode".

There is a `!` method and methods for `|` and `&`: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

See Also

`octmode`, `sprintf` for other options in converting integers to hex, `strtoi` to convert hex strings to integers.

Examples

```
i <- as.hexmode("7fffffff")
i; class(i)
identical(as.integer(i), .Machine$integer.max)

hm <- as.hexmode(c(NA, 1)); hm
as.integer(hm)

Xm <- as.hexmode(1:16)
Xm # print()s via format()
stopifnot(nchar(format(Xm)) == 2)
Xm[-16] # *no* leading zeroes!
stopifnot(format(Xm[-16]) == c(1:9, letters[1:6]))

## Integer arithmetic (remaining "hexmode"):
16*Xm
Xm^2
-Xm
(fac <- factorial(Xm[1:12])) # !1, !2, !3, !4 .. in hexadecimals
as.integer(fac) # indeed the same as factorial(1:12)
```

Hyperbolic

*Hyperbolic Functions***Description**

These functions give the obvious hyperbolic functions. They respectively compute the hyperbolic cosine, sine, tangent, and their inverses, arc-cosine, arc-sine, arc-tangent (or ‘*area cosine*’, etc).

Usage

```
cosh(x)
sinh(x)
tanh(x)
acosh(x)
asinh(x)
atanh(x)
```

Arguments

`x` a numeric or complex vector

Details

These are [internal generic primitive](#) functions: methods can be defined for them individually or via the [Math](#) group generic.

Branch cuts are consistent with the inverse trigonometric functions *asin et seq*, and agree with those defined in Abramowitz and Stegun (1972, figure 4.7 on page 86). The behaviour actually

on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

S4 methods

All are S4 generic functions: methods can be defined for them individually or via the [Math](#) group generic.

The logistic distribution function [plogis](#) is a shifted version of `tanh()` for numeric `x`.

iconv

Convert Character Vector between Encodings

Description

This uses system facilities to convert a character vector between encodings: the ‘i’ stands for ‘internationalization’.

Usage

```
iconv(x, from = "", to = "", sub = NA, mark = TRUE, toRaw = FALSE)
```

```
iconvlist()
```

Arguments

<code>x</code>	a character vector, or an object to be converted to a character vector by as.character , or a list with <code>NULL</code> and <code>raw</code> elements as returned by <code>iconv(toRaw = TRUE)</code> .
<code>from</code>	a character string describing the current encoding.
<code>to</code>	a character string describing the target encoding.
<code>sub</code>	character string. If not <code>NA</code> it is used to replace any non-convertible bytes in the input. (This would normally be a single character, but can be more.) If <code>"byte"</code> , the indication is <code>"<xx>"</code> with the hex code of the byte. If <code>"Unicode"</code> and converting from UTF-8, the Unicode point in the form <code>"<U+xxxx>"</code> , or if <code>c99</code> , a C99-style escape <code>"\uxxxx"</code> . (For points in a ‘supplementary plane’, <code>"\Uxxxxxxxx"</code> is used, with zero-padding)
<code>mark</code>	logical, for expert use. Should encodings be marked?
<code>toRaw</code>	logical. Should a list of raw vectors be returned rather than a character vector?

Details

The names of encodings and which ones are available are platform-dependent. All R platforms support "" (for the encoding of the current locale), "latin1" and "UTF-8". Generally case is ignored when specifying an encoding.

On most platforms `iconvlist` provides an alphabetical list of the supported encodings (including aliases). On 'musl' (as used by Alpine Linux and other lightweight Linux distributions) the listing is incomplete. On others, the information is on the man page for `iconv(5)` or elsewhere in the man pages (but beware that the system command `iconv` may not support the same set of encodings as the C functions R calls). Unfortunately, the names are rarely supported across all platforms.

Elements of `x` which cannot be converted (perhaps because they are invalid or because they cannot be represented in the target encoding) will be returned as NA (or NULL for `toRaw = TRUE`) unless `sub` is specified.

Most versions of `iconv` will allow transliteration by appending `'//TRANSLIT'` to the `to` encoding: see the examples.

Encoding "ASCII" is accepted, and on most systems "C" and "POSIX" are synonyms for ASCII. Where "ASCII//TRANSLIT" is unsupported by the OS, "ASCII" is used with `sub = "c99"` if from UTF-8, else `sub = "?"`. (However, musl's version of "ASCII" substitutes *.)

Elements of `x` with a declared encoding (UTF-8 or latin1, see [Encoding](#)) are converted from that encoding if `from = ""`, otherwise they are taken as being in the encoding specified by `from`.

Note that implementations of `iconv` typically do not do much validity checking and will often mis-convert inputs which are invalid in encoding `from`.

If `sub = "Unicode"` or `sub = "c99"` is used for a non-UTF-8 input it is the same as `sub = "byte"`.

Value

If `toRaw = FALSE` (the default), the value is a character vector of the same length and the same attributes as `x` (after conversion to a character vector). If conversion fails for an element that element of the result is set to `NA_character_`. (NB: whether conversion fails is implementation-specific.) `NA_character_` inputs give `NA_character_` outputs.

If `mark = TRUE` (the default) the elements of the result have a declared encoding if `to` is "latin1" or "UTF-8", or if `to = ""` and the current locale's encoding is detected as Latin-1 (or its superset CP1252 on Windows) or UTF-8.

If `toRaw = TRUE`, the value is a list of the same length and the same attributes as `x` whose elements are either NULL (if conversion fails or the input was `NA_character_`) or a raw vector.

For `iconvlist()`, a character vector (typically of a few hundred elements) of known encoding names.

Implementation Details

There are three main implementations of `iconv` in use. Linux's most common C runtime, 'glibc', contains one. Several platforms supply versions or emulations of GNU 'libiconv', including previous versions of macOS and FreeBSD, in some cases with additional encodings. On Windows we use a version of Yukihiro Nakadaira's 'win_iconv', which is based on Windows' codepages. (We have added many encoding names for compatibility with other systems.) All three have `iconvlist`, ignore case in encoding names and support `'//TRANSLIT'` (but with different results, and for 'win_iconv' currently a 'best fit' strategy is used except for `to = "ASCII"`).

The macOS 14 implementation is attributed to the 'Citrus Project': the Apple headers declare it as 'compatible' with GNU 'libiconv' 1.11 from 2006. However, it differs in significant ways

including using transliteration for conversions which cannot be represented exactly in the target encoding. (It seems this implementation is also used in recent versions of FreeBSD. Earlier versions of macOS used GNU ‘libiconv’ 1.11 and some CRAN builds still do.) For a failing conversion macOS 14 generally translated character(s) to ? but 14.1 gives an error (so an NA result in R).

Most commercial Unixes contain an implementation of `iconv` but none we have encountered have supported the encoding names we need: *R Installation and Administration* recommended installing GNU ‘libiconv’ on Solaris and AIX.

Some Linux distributions use ‘musl’ as their C runtime. This is less comprehensive than ‘glibc’: it does not support ‘//TRANSLIT’ but does inexact conversions (currently using ‘*’).

There are other implementations, e.g. NetBSD has used one from the Citrus project (which does not support ‘//TRANSLIT’) and there is an older FreeBSD port.

Note that you cannot rely on invalid inputs being detected, especially for `to = "ASCII"` where some implementations allow 8-bit characters and pass them through unchanged or with transliteration or substitution.

Some of the implementations have interesting extra encodings: for example GNU ‘libiconv’ and macOS 14 allow `to = "C99"` to use ‘\uxxxx’ escapes (or if needed ‘\Uxxxxxxxxxx’) for non-ASCII characters.

Byte Order Marks

most commonly known as ‘BOMs’.

Encodings using character units which are more than one byte in size can be written on a file in either big-endian or little-endian order: this applies most commonly to UCS-2, UTF-16 and UTF-32/UCS-4 encodings. Some systems will write the Unicode character U+FEFF at the beginning of a file in these encodings and perhaps also in UTF-8. In that usage the character is known as a BOM, and should be handled during input (see the ‘Encodings’ section under [connection](#): re-encoded connections have some special handling of BOMs). The rest of this section applies when this has not been done so `x` starts with a BOM.

Implementations will generally interpret a BOM for `from` given as one of "UCS-2", "UTF-16" and "UTF-32". Implementations differ in how they treat BOMs in `x` in other `from` encodings: they may be discarded, returned as character U+FEFF or regarded as invalid.

Note

The most portable name for the ISO 8859-15 encoding, commonly known as ‘Latin 9’, is "iso885915": most platforms support both "latin-9" and "latin9" but GNU ‘libiconv’ does not support the latter.

Encoding names "utf8", "mac" and "macroman" are not portable. "utf8" is converted to "UTF-8" for `from` and `to` by `iconv`, but not for e.g. `fileEncoding` arguments. "macintosh" is the official (and most widely supported) name for ‘Mac Roman’ (https://en.wikipedia.org/wiki/Mac_OS_Roman).

Using `sub` substitutes each non-convertible *byte* in the input, so when converting from UTF-8 a non-convertible character may be replaced by two or more bytes. Using `sub = "C99"` or `sub = "Unicode"` will be clearer.

Examples

```
## In principle, as not all systems have iconvlist
try(utils::head(iconvlist(), n = 50))

## Not run:
## convert from Latin-2 to UTF-8: two of the glibc iconv variants.
iconv(x, "ISO_8859-2", "UTF-8")
iconv(x, "LATIN2", "UTF-8")

## End(Not run)

## Both x below are in latin1 and will only display correctly in a
## locale that can represent and display latin1.
x <- "fran\xE7ais"
Encoding(x) <- "latin1"
x
charToRaw(xx <- iconv(x, "latin1", "UTF-8"))
xx

## The results in the comments are those from glibc and GNU libiconv
iconv(x, "latin1", "ASCII")          # NA
iconv(x, "latin1", "ASCII", "?")     # "fran?ais"
iconv(x, "latin1", "ASCII", "")      # "franais"
iconv(x, "latin1", "ASCII", "byte")  # "fran<e7>ais"
iconv(xx, "UTF-8", "ASCII", "Unicode") # "fran<U+00E7>ais"
iconv(xx, "UTF-8", "ASCII", "c99")   # "fran\\u00e7ais"

## Extracts from old R help files (they are nowadays in UTF-8)
x <- c("Ekstr\xF8m", "J\xF6reskog", "bi\xdfchen Z\xfccher")
Encoding(x) <- "latin1"
x
try(iconv(x, "latin1", "ASCII//TRANSLIT")) # platform-dependent
## glibc gives "Ekstroem" "Joreskog" "bisschen Zurcher"
## macOS 14 gives "Ekstrom" "J\"oreskog" "bisschen Z\"urcher"
## musl gives "Ekstr*m" "J*reskog" "bi*chen Z*rcher"
iconv(x, "latin1", "ASCII", sub = "byte")

## and for Windows' 'Unicode'
str(xx <- iconv(x, "latin1", "UTF-16LE", toRaw = TRUE))
iconv(xx, "UTF-16LE", "UTF-8")

emoji <- "\U0001f604"
iconv(emoji,, "latin1", sub = "Unicode") # "<U+1F604>"
iconv(emoji,, "latin1", sub = "c99")
```

Description

Controls the way collation is done by ICU (an optional part of the R build).

Usage

```
icuSetCollate(...)

icuGetCollate(type = c("actual", "valid"))
```

Arguments

`...` named arguments, see ‘Details’.

`type` a character string: either the "actual" locale in use for collation, or the most specific locale which would be "valid". Can be abbreviated.

Details

Optionally, R can be built to collate character strings by ICU (<https://icu.unicode.org/>). For such systems, `icuSetCollate` can be used to tune the way collation is done. On other builds calling this function does nothing, with a warning.

Possible arguments are

locale: A character string such as "da_DK" giving the language and country whose collation rules are to be used. If present, this should be the first argument.

case_first: "upper", "lower" or "default", asking for upper- or lower-case characters to be sorted first. The default is usually lower-case first, but not in all languages (not under the default settings for Danish, for example).

alternate_handling: Controls the handling of ‘variable’ characters (mainly punctuation and symbols). Possible values are "non_ignorable" (primary strength) and "shifted" (quaternary strength).

strength: Which components should be used? Possible values "primary", "secondary", "tertiary" (default), "quaternary" and "identical".

french_collation: In a French locale the way accents affect collation is from right to left, whereas in most other locales it is from left to right. Possible values "on", "off" and "default".

normalization: Should strings be normalized? Possible values are "on" and "off" (default). This affects the collation of composite characters.

case_level: An additional level between secondary and tertiary, used to distinguish large and small Japanese Kana characters. Possible values "on" and "off" (default).

hiragana_quaternary: Possible values "on" (sort Hiragana first at quaternary level) and "off".

Only the first three are likely to be of interest except to those with a detailed understanding of collation and specialized requirements.

Some special values are accepted for `locale`:

"none": ICU is not used for collation: the OS’s collation services are used instead.

"ASCII": ICU is not used for collation: the C function `strcmp` is used instead, which should sort byte-by-byte in (unsigned) numerical order.

"default": obtains the locale from the OS as is done at the start of the session (except on Windows). If environment variable `R_ICU_LOCALE` is set to a non-empty value, its value is used rather than consulting the OS, unless environment variable `LC_ALL` is set to 'C' (or unset but `LC_COLLATE` is set to 'C').

`"", "root"`: the ‘root’ collation: see https://www.unicode.org/reports/tr35/tr35-collation.html#Root_Collation.

For the specifications of ‘real’ ICU locales, see <https://unicode-org.github.io/icu/userguide/locale/>. Note that ICU does not report that a locale is not supported, but falls back to its idea of ‘best fit’ (which could be rather different and is reported by `icuGetCollate("actual")`, often `"root"`). Most English locales fall back to `"root"` as although e.g. `"en_GB"` is a valid locale (at least on some platforms), it contains no special rules for collation. Note that `"C"` is not a supported ICU locale and hence `R_ICU_LOCALE` should never be set to `"C"`.

Some examples are `case_level = "on"`, `strength = "primary"` to ignore accent differences and `alternate_handling = "shifted"` to ignore space and punctuation characters.

Initially ICU will not be used for collation if the OS is set to use the `C` locale for collation and `R_ICU_LOCALE` is not set. Once this function is called with a value for `locale`, ICU will be used until it is called again with `locale = "none"`. ICU will not be used once `Sys.setlocale` is called with a `"C"` value for `LC_ALL` or `LC_COLLATE`, even if `R_ICU_LOCALE` is set. ICU will be used again honoring `R_ICU_LOCALE` once `Sys.setlocale` is called to set a different collation order. Environment variables `LC_ALL` (or `LC_COLLATE`) take precedence over `R_ICU_LOCALE` if and only if they are set to `'C'`. Due to the interaction with other ways of setting the collation order, `R_ICU_LOCALE` should be used with care and only when needed.

All customizations are reset to the default for the locale if `locale` is specified: the collation engine is reset if the OS collation locale category is changed by `Sys.setlocale`.

Value

For `icuGetCollate`, a character string describing the ICU locale in use (which may be reported as `"ICU not in use"`). The ‘actual’ locale may be simpler than the requested locale: for example `"da"` rather than `"da_DK"`: English locales are likely to report `"root"`.

Note

Except on Windows, ICU is used by default wherever it is available. As it works internally in UTF-8, it will be most efficient in UTF-8 locales.

On Windows, `R` is normally built including ICU, but it will only be used if environment variable `R_ICU_LOCALE` had been set when `R` is started or after `icuSetCollate` is called to select the locale (as ICU and Windows differ in their idea of locale names). Note that `icuSetCollate(locale = "default")` should work reasonably well, but finds the system default ignoring environment variables such as `LC_COLLATE`.

See Also

[Comparison, sort](#).

[capabilities](#) for whether ICU is available; [extSoftVersion](#) for its version.

The ICU user guide chapter on collation (<https://unicode-org.github.io/icu/userguide/collation/>).

Examples

```
## These examples depend on having ICU available, and on the locale.
## As we don't know the current settings, we can only reset to the default.
if(capabilities("ICU")) withAutoprint({
  icuGetCollate()
```

```

icuGetCollate("valid")
x <- c("Aarhus", "aarhus", "safe", "test", "Zoo")
sort(x)
icuSetCollate(case_first = "upper"); sort(x)
icuSetCollate(case_first = "lower"); sort(x)

## Danish collates upper-case-first and with 'aa' as a single letter
icuSetCollate(locale = "da_DK", case_first = "default"); sort(x)
## Estonian collates Z between S and T
icuSetCollate(locale = "et_EE"); sort(x)
icuSetCollate(locale = "default"); icuGetCollate("valid")
})

```

identical

Test Objects for Exact Equality

Description

The safe and reliable way to test two objects for being *exactly* equal. It returns TRUE in this case, FALSE in every other case.

Usage

```

identical(x, y, num.eq = TRUE, single.NA = TRUE, attrib.as.set = TRUE,
          ignore.bytecode = TRUE, ignore.environment = FALSE,
          ignore.srcref = TRUE, extptr.as.ref = FALSE)

```

Arguments

x, y	any R objects.
num.eq	logical indicating if (double and complex non-NA) numbers should be compared using == ('equal'), or by bitwise comparison. The latter (non-default) differentiates between -0 and +0.
single.NA	logical indicating if there is conceptually just one numeric NA and one NaN; single.NA = FALSE differentiates bit patterns.
attrib.as.set	logical indicating if attributes of x and y should be treated as unordered tagged pairlists ("sets"); this currently also applies to slots of S4 objects. It may well be too strict to set attrib.as.set = FALSE.
ignore.bytecode	logical indicating if byte code should be ignored when comparing closures.
ignore.environment	logical indicating if their environments should be ignored when comparing closures.
ignore.srcref	logical indicating if their "srcref" attributes should be ignored when comparing closures.
extptr.as.ref	logical indicating whether external pointer objects should be compared as reference objects and considered identical only if they are the same object in memory. By default, external pointers are considered identical if the addresses they contain are identical.

Details

A call to `identical` is the way to test exact equality in `if` and `while` statements, as well as in logical expressions that use `&&` or `||`. In all these applications you need to be assured of getting a single logical value.

Users often use the comparison operators, such as `==` or `!=`, in these situations. It looks natural, but it is not what these operators are designed to do in R. They return an object like the arguments. If you expected `x` and `y` to be of length 1, but it happened that one of them was not, you will *not* get a single `FALSE`. Similarly, if one of the arguments is `NA`, the result is also `NA`. In either case, the expression `if (x == y) . . .` won't work as expected.

The function `all.equal` is also sometimes used to test equality this way, but was intended for something different: it allows for small differences in numeric results.

The computations in `identical` are also reliable and usually fast. There should never be an error. The only known way to kill `identical` is by having an invalid pointer at the C level, generating a memory fault. It will usually find inequality quickly. Checking equality for two large, complicated objects can take longer if the objects are identical or nearly so, but represent completely independent copies. For most applications, however, the computational cost should be negligible.

If `single.NA` is true, as by default, `identical` sees `NaN` as different from `NA_real_`, but all `NaN`s are equal (and all `NA` of the same type are equal).

Character strings (except those in marked encoding "bytes") are regarded as identical even if they are in different marked encodings but would agree when translated to UTF-8. A character string in marked encoding "bytes" is only regarded as identical to a character string in the same encoding and with the same content.

If `attrib.as.set` is true, as by default, comparison of attributes view them as a set (and not a vector, so order is not tested).

If `ignore.bytecode` is true (the default), the compiled bytecode of a function (see `cmpfun`) will be ignored in the comparison. If it is false, functions will compare equal only if they are copies of the same compiled object (or both are uncompiled). To check whether two different compiles are equal, you should compare the results of `disassemble()`.

You almost never want to use `identical` on datetimes of class "POSIXlt": not only can different times in the different time zones represent the same time and time zones have multiple names, but several of the components are optional.

Note that the strictest test for equality is

```
identical(x, y,
          num.eq = FALSE, single.NA = FALSE, attrib.as.set = FALSE,
          ignore.bytecode = FALSE, ignore.environment = FALSE,
          ignore.srcref = FALSE, extptr.as.ref = TRUE)
```

Value

A single logical value, `TRUE` or `FALSE`, never `NA` and never anything other than a single value.

See Also

[all.equal](#) for descriptions of how two objects differ; [Comparison](#) and [Logic](#) for element-wise comparisons.

Examples

```
identical(1, NULL) ## FALSE -- don't try this with ==
identical(1, 1.)   ## TRUE in R (both are stored as doubles)
identical(1, as.integer(1)) ## FALSE, stored as different types

x <- 1.0; y <- 0.999999999999
## how to test for object equality allowing for numeric fuzz :
(E <- all.equal(x, y))
identical(TRUE, E)
isTRUE(E) # alternative test
## If all.equal thinks the objects are different, it returns a
## character string, and the above expression evaluates to FALSE

## even for unusual R objects :
identical(.GlobalEnv, environment())

### ----- Pickyness Flags : -----

## the infamous example:
identical(0., -0.) # TRUE, i.e. not differentiated
identical(0., -0., num.eq = FALSE)
## similar:
identical(NaN, -NaN) # TRUE
identical(NaN, -NaN, single.NA = FALSE) # differ on bit-level

### For functions ("closure"s): -----
###      ~~~~~~
f <- function(x) x
f
g <- compiler::cmpfun(f)
g
identical(f, g) # TRUE, as bytecode is ignored by default
identical(f, g, ignore.bytecode=FALSE) # FALSE: bytecode differs

## GLM families contain several functions, some of which share an environment:
p1 <- poisson() ; p2 <- poisson()
identical(p1, p2) # FALSE
identical(p1, p2, ignore.environment=TRUE) # TRUE

## in interactive use, the 'keep.source' option is typically true:
op <- options(keep.source = TRUE) # and so, these have differing "srcfile" :
f1 <- function() {}
f2 <- function() {}
identical(f1, f2) # ignore.srcfile= TRUE : TRUE
identical(f1, f2, ignore.srcfile=FALSE) # FALSE
options(op) # revert to previous state
```

identity	<i>Identity Function</i>
----------	--------------------------

Description

A trivial identity function returning its argument.

Usage

```
identity(x)
```

Arguments

`x` an R object.

See Also

[diag](#) creates diagonal matrices, including identity ones.

ifelse	<i>Conditional Element Selection</i>
--------	--------------------------------------

Description

`ifelse` returns a value with the same shape as `test` which is filled with elements selected from either `yes` or `no` depending on whether the element of `test` is TRUE or FALSE.

Usage

```
ifelse(test, yes, no)
```

Arguments

<code>test</code>	an object which can be coerced to logical mode.
<code>yes</code>	return values for true elements of <code>test</code> .
<code>no</code>	return values for false elements of <code>test</code> .

Details

If `yes` or `no` are too short, their elements are recycled. `yes` will be evaluated if and only if any element of `test` is true, and analogously for `no`.

Missing values in `test` give missing values in the result.

Value

A vector of the same length and attributes (including dimensions and "class") as `test` and data values from the values of `yes` or `no`. The mode of the answer will be coerced from logical to accommodate first any values taken from `yes` and then any values taken from `no`.

Warning

The mode of the result may depend on the value of `test` (see the examples), and the class attribute (see `oldClass`) of the result is taken from `test` and may be inappropriate for the values selected from `yes` and `no`.

Sometimes it is better to use a construction such as

```
(tmp <- yes; tmp[!test] <- no[!test]; tmp)
```

, possibly extended to handle missing values in `test`.

Further note that `if(test) yes else no` is much more efficient and often much preferable to `ifelse(test, yes, no)` whenever `test` is a simple true/false result, i.e., when `length(test) == 1`.

The `srcref` attribute of functions is handled specially: if `test` is a simple true result and `yes` evaluates to a function with `srcref` attribute, `ifelse` returns `yes` including its attribute (the same applies to a false `test` and `no` argument). This functionality is only for backwards compatibility, the form `if(test) yes else no` should be used whenever `yes` and `no` are functions.

[if](#).

Examples

```
x <- c(6:-4)
sqrt(x)  #- gives warning
sqrt(ifelse(x >= 0, x, NA))  # no warning

## Note: the following also gives the warning !
ifelse(x >= 0, sqrt(x), NA)

## ifelse() strips attributes
## This is important when working with Dates and factors
x <- seq(as.Date("2000-02-29"), as.Date("2004-10-04"), by = "1 month")
## has many "yyyy-mm-29", but a few "yyyy-03-01" in the non-leap years
y <- ifelse(as.POSIXlt(x)$mday == 29, x, NA)
head(y) # not what you expected ... ==> need restore the class attribute:
class(y) <- class(x)
y
## This is a (not atypical) case where it is better *not* to use ifelse(),
## but rather the more efficient and still clear:
y2 <- x
y2[as.POSIXlt(x)$mday != 29] <- NA
## which gives the same as ifelse()+class() hack:
stopifnot(identical(y2, y))

## example of different return modes (and 'test' alone determining length):
yes <- 1:3
```

```
no <- pi^(1:4)
utils::str( ifelse(NA,    yes, no) ) # logical, length 1
utils::str( ifelse(TRUE,  yes, no) ) # integer, length 1
utils::str( ifelse(FALSE, yes, no) ) # double,  length 1
```

integer	<i>Integer Vectors</i>
---------	------------------------

Description

Creates or tests for objects of type "integer".

Usage

```
integer(length = 0)
as.integer(x, ...)
is.integer(x)
```

Arguments

length	a non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

Integer vectors exist so that data can be passed to C or Fortran code which expects them, and so that (small) integer data can be represented exactly and compactly.

Note that current implementations of R use 32-bit integers for integer vectors, so the range of representable integers is restricted to about $\pm 2 \times 10^9$: [doubles](#) can hold much larger integers exactly.

Value

`integer` creates a integer vector of the specified length. Each element of the vector is equal to 0. `as.integer` attempts to coerce its argument to be of integer type. The answer will be NA unless the coercion succeeds. Real values larger in modulus than the largest integer are coerced to NA (unlike S which gives the most extreme integer of the same sign). Non-integral numeric values are truncated towards zero (i.e., `as.integer(x)` equals `trunc(x)` there), and imaginary parts of complex numbers are discarded (with a warning). Character strings containing optional whitespace followed by either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as well as any allowed by the platform for real numbers. Like [as.vector](#) it strips attributes including names. (To ensure that an object `x` is of integer type without stripping attributes, use `storage.mode(x) <- "integer"`.)

`is.integer` returns TRUE or FALSE depending on whether its argument is of integer [type](#) or not, unless it is a factor when it returns FALSE.

Note

`is.integer(x)` does **not** test if `x` contains integer numbers! For that, use [round](#), as in the function `is.wholenumber(x)` in the examples.

References

See Also

`numeric`, `storage.mode`.
`round` (and `ceiling` and `floor` on that help page) to convert to integral values.

Examples

```
## as.integer() truncates:
x <- pi * c(-1:1, 10)
as.integer(x)

is.integer(1) # is FALSE !

is.wholenumber <-
  function(x, tol = .Machine$double.eps^0.5) abs(x - round(x)) < tol
is.wholenumber(1) # is TRUE
(x <- seq(1, 5, by = 0.5) )
is.wholenumber( x ) #--> TRUE FALSE TRUE ...
```

interaction

Compute Factor Interactions

Description

`interaction` computes a factor which represents the interaction of the given factors. The result of `interaction` is always unordered.

Usage

```
interaction(..., drop = FALSE, sep = ".", lex.order = FALSE)
```

Arguments

<code>...</code>	the factors for which <code>interaction</code> is to be computed, or a single list giving those factors.
<code>drop</code>	if <code>drop</code> is <code>TRUE</code> , unused factor levels are dropped from the result. The default is to retain all factor levels.
<code>sep</code>	string to construct the new level labels by joining the constituent ones.
<code>lex.order</code>	logical indicating if the order of factor concatenation should be lexically ordered.

Value

A factor which represents the interaction of the given factors. The levels are labelled as the levels of the individual factors joined by `sep` which is `.` by default.

By default, when `lex.order = FALSE`, the levels are ordered so the level of the first factor varies fastest, then the second and so on. This is the reverse of lexicographic ordering (which you can get by `lex.order = TRUE`), and differs from `:`. (It is done this way for compatibility with S.)

See Also

`factor`; `:` where `f:g` is similar to `interaction(f, g, sep = ":")` when `f` and `g` are factors.

Examples

```
a <- gl(2, 4, 8)
b <- gl(2, 2, 8, labels = c("ctrl", "treat"))
s <- gl(2, 1, 8, labels = c("M", "F"))
interaction(a, b)
interaction(a, b, s, sep = ":")
stopifnot(identical(a:s,
                    interaction(a, s, sep = ":", lex.order = TRUE)),
          identical(a:s:b,
                    interaction(a, s, b, sep = ":", lex.order = TRUE)))
```

interactive

Is R Running Interactively?

Description

Return `TRUE` when `R` is being used interactively and `FALSE` otherwise.

Usage

```
interactive()
```

Details

An interactive `R` session is one in which it is assumed that there is a human operator to interact with, so for example `R` can prompt for corrections to incorrect input or ask what to do next or if it is OK to move to the next plot.

GUI consoles will arrange to start `R` in an interactive session. When `R` is run in a terminal (via `Rterm.exe` on Windows), it assumes that it is interactive if ‘`stdin`’ is connected to a (pseudo-)terminal and not if ‘`stdin`’ is redirected to a file or pipe. Command-line options ‘`--interactive`’ (Unix) and ‘`--ess`’ (Windows, `Rterm.exe`) override the default assumption. (On a Unix-alike, whether the `readline` command-line editor is used is **not** overridden by ‘`--interactive`’.)

Embedded uses of `R` can set a session to be interactive or not.

Internally, whether a session is interactive determines

- how some errors are handled and reported, e.g. see `stop` and `options("showWarnCalls")`.
- whether one of ‘`--save`’, ‘`--no-save`’ or ‘`--vanilla`’ is required, and if `R` ever asks whether to save the workspace.

- the choice of default graphics device launched when needed and by `dev.new`: see `options("device")`
- whether graphics devices ever ask for confirmation of a new page.

In addition, R's own R code makes use of `interactive()`: for example `help`, `debugger` and `install.packages` do.

Note

This is a `primitive` function.

See Also

`source`, `.First`

Examples

```
.First <- function() if(interactive()) x11()
```

Internal

Call an Internal Function

Description

`.Internal` performs a call to an internal code which is built in to the R interpreter.

Only true R wizards should even consider using this function, and only R developers can add to the list of internal functions.

Usage

```
.Internal(call)
```

Arguments

`call` a call expression

See Also

`.Primitive`, `.External` (the nearest equivalent available to users).

Description

Many R-internal functions are *generic* and allow methods to be written for.

Details

The following primitive and internal functions are *generic*, i.e., you can write `methods` for them:

```
[, [[, $, [<-, [[<-, $<-,
length, length<-, lengths, dimnames, dimnames<-, dim, dim<-, names, names<-,
levels<-, @, @<-,
c, unlist, cbind, rbind,
as.character, as.complex, as.double, as.integer, as.logical, as.raw,
as.vector, as.call, as.environment is.array, is.matrix, is.na, anyNA,
is.nan, is.finite is.infinite is.numeric, nchar rep, rep.int rep_len
seq.int (which dispatches methods for "seq"), is.unsorted and xtfm
```

In addition, `as.numeric` is a synonym for `as.double` and dispatches methods for the latter, i.e., S3 methods are for `as.double`, whereas S4 methods are to be written for `as.numeric`.

Note that all of the `group generic` functions are also internal/primitive and allow methods to be written for them.

`.S3PrimitiveGenerics` is a character vector listing the primitives which are internal generic and not `group generic`, (not only for S3 but also S4). Similarly, the `.internalGenerics` character vector contains the names of the internal (via `.Internal(. .)`) non-primitive functions which are internally generic.

Note

For efficiency, internal dispatch only occurs on *objects*, that is those for which `is.object` returns true.

See Also

`methods` for the methods which are available.

Description

Return a (temporarily) invisible copy of an object.

Usage

```
invisible(x = NULL)
```

Arguments

`x` an arbitrary R object, by default `NULL`.

Details

This function can be useful when it is desired to have functions return values which can be assigned, but which do not print when they are not assigned.

This is a [primitive](#) function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[withVisible](#), [return](#), [function](#).

Examples

```
# These functions both return their argument
f1 <- function(x) x
f2 <- function(x) invisible(x)
f1(1)  # prints
f2(1)  # does not
```

is.finite

Finite, Infinite and NaN Numbers

Description

`is.finite` and `is.infinite` return a vector of the same length as `x`, indicating which elements are finite (not infinite and not missing) or infinite.

`Inf` and `-Inf` are positive and negative infinity whereas `NaN` means ‘Not a Number’. (These apply to numeric values and real and imaginary parts of complex values but not to values of integer vectors.) `Inf` and `NaN` (as well as [NA](#)) are [reserved](#) words in the R language.

Usage

```
is.finite(x)
is.infinite(x)
is.nan(x)
```

`Inf`
`NaN`

Arguments

`x` R object to be tested: the default methods handle atomic vectors.

Details

`is.finite` returns a vector of the same length as `x` the `j`-th element of which is `TRUE` if `x[j]` is finite (i.e., it is not one of the values `NA`, `NaN`, `Inf` or `-Inf`) and `FALSE` otherwise. Complex numbers are finite if both the real and imaginary parts are.

`is.infinite` returns a vector of the same length as `x` the `j`-th element of which is `TRUE` if `x[j]` is infinite (i.e., equal to one of `Inf` or `-Inf`) and `FALSE` otherwise. This will be false unless `x` is numeric or complex. Complex numbers are infinite if either the real or the imaginary part is.

`is.nan` tests if a numeric value is `NaN`. Do not test equality to `NaN`, or even use `identical`, since systems typically have many different `NaN` values. One of these is used for the numeric missing value `NA`, and `is.nan` is false for that value. A complex number is regarded as `NaN` if either the real or imaginary part is `NaN` but not `NA`. All elements of logical, integer and raw vectors are considered not to be `NaN`.

All three functions accept `NULL` as input and return a length zero result. The default methods accept character and raw vectors, and return `FALSE` for all entries. Prior to R version 2.14.0 they accepted all input, returning `FALSE` for most non-numeric values; cases which are not atomic vectors are now signalled as errors.

All three functions are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Value

A logical vector of the same length as `x`: `dim`, `dimnames` and `names` attributes are preserved.

Note

In R, basically all mathematical functions (including basic [Arithmetic](#)), are supposed to work properly with `+/- Inf` and `NaN` as input or output.

The basic rule should be that calls and relations with `Infs` really are statements with a proper mathematical *limit*.

Computations involving `NaN` will return `NaN` or perhaps `NA`: which of those two is not guaranteed and may depend on the R platform (since compilers may re-order computations).

[NA](#), ‘Not Available’ which is not a number as well, however usually used for missing values and applies to many modes, not just numeric and complex.

[Arithmetic](#), [double](#).

Examples

```

pi / 0 ## = Inf a non-zero number divided by zero creates infinity
0 / 0  ## = NaN

1/0 + 1/0 # Inf
1/0 - 1/0 # NaN

stopifnot(
  1/0 == Inf,
  1/Inf == 0
)
sin(Inf)
cos(Inf)
tan(Inf)

```

is.function

Is an Object of Type (Primitive) Function?

Description

Checks whether its argument is a (primitive) function.

Usage

```

is.function(x)
is.primitive(x)

```

Arguments

`x` an R object.

Details

`is.primitive(x)` tests if `x` is a [primitive](#) function, i.e, if `typeof(x)` is either "builtin" or "special".

Value

TRUE if `x` is a (primitive) function, and FALSE otherwise.

Examples

```

is.function(1) # FALSE
is.function(is.primitive) # TRUE: it is a function, but ..
is.primitive(is.primitive) # FALSE: it's not a primitive one, whereas
is.primitive(is.function) # TRUE: that one is

```

is.language	<i>Is an Object a Language Object?</i>
-------------	--

Description

is.language returns TRUE if x is a variable [name](#), a [call](#), or an [expression](#).

Usage

```
is.language(x)
```

Arguments

x object to be tested.

Note

A name is also known as ‘symbol’, from its type ([typeof](#)), see [is.symbol](#).

If [typeof](#)(x) == "language", then is.language(x) is always true, but the reverse does not hold as expressions or names y also fulfill is.language(y), see the examples.

This is a [primitive](#) function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Examples

```
ll <- list(a = expression(x^2 - 2*x + 1), b = as.name("Jim"),
          c = as.expression(exp(1)), d = call("sin", pi))
sapply(ll, typeof)
sapply(ll, mode)
stopifnot(sapply(ll, is.language))
```

is.object	<i>Is an Object ‘internally classed’?</i>
-----------	---

Description

A function mostly for internal use. It returns TRUE if the object x has the R internal OBJECT bit set, and FALSE otherwise. The OBJECT bit is set when a "class" attribute is added and removed when that attribute is removed, so this is a very efficient way to check if an object has a class attribute. (S4 objects always should.)

Note that typical basic (‘atomic’, see [is.atomic](#)) R vectors and arrays x are *not* objects in the above sense as [attributes](#)(x) does *not* contain "class".

Usage

```
is.object(x)
```

Arguments

`x` object to be tested.

Note

This is a [primitive](#) function.

See Also

[class](#), and [methods](#).
[isS4](#).

Examples

```
is.object(1) # FALSE
is.object(as.factor(1:3)) # TRUE
```

is.recursive

Is an Object Atomic or Recursive?

Description

`is.atomic` returns TRUE if `x` is of an atomic type and FALSE otherwise. `is.atomic(NULL)` returns FALSE since R version 4.4.0.

`is.recursive` returns TRUE if `x` has a recursive (list-like) structure and FALSE otherwise.

Usage

```
is.atomic(x)
is.recursive(x)
```

Arguments

`x` object to be tested.

Details

`is.atomic` is true for the [atomic](#) types ("logical", "integer", "numeric", "complex", "character" and "raw").

Most types of objects are regarded as recursive. Exceptions are the atomic types, NULL, symbols (as given by [as.name](#)), S4 objects with slots, external pointers, and—rarely visible from R—weak references and byte code, see [typeof](#).

It is common to call the atomic types ‘atomic vectors’, but note that [is.vector](#) imposes further restrictions: an object can be atomic but not a vector (in that sense).

These are [primitive](#) functions.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`is.list`, `is.language`, etc, and the demo (`"is.things"`).

Examples

```
require(stats)

is.a.r <- function(x) c(is.atomic(x), is.recursive(x))

is.a.r(c(a = 1, b = 3)) # TRUE FALSE
is.a.r(list())          # FALSE TRUE - a list is a list
is.a.r(list(2))         # FALSE TRUE
is.a.r(lm)              # FALSE TRUE
is.a.r(y ~ x)           # FALSE TRUE
is.a.r(expression(x+1)) # FALSE TRUE
is.a.r(quote(exp))      # FALSE FALSE
is.a.r(NULL)            # FALSE FALSE

# Reproduce pre-4.4 behavior of is.atomic()
is.atomicN <- function(x) is.atomic(x) || is.null(x)
is.atomicN(NULL) # TRUE
```

is.single

Is an Object of Single Precision Type?

Description

`is.single` reports an error. There are no single precision values in R.

Usage

```
is.single(x)
```

Arguments

`x` object to be tested.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

<code>is.unsorted</code>	<i>Test if an Object is Not Sorted</i>
--------------------------	--

Description

Test if an object is not sorted (in increasing order), without the cost of sorting it.

Usage

```
is.unsorted(x, na.rm = FALSE, strictly = FALSE)
```

Arguments

<code>x</code>	an R object with a class or a numeric, complex, character, logical or raw vector.
<code>na.rm</code>	logical. Should missing values be removed before checking?
<code>strictly</code>	logical indicating if the check should be for <i>strictly</i> increasing values.

Details

`is.unsorted` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Value

A length-one logical value. All objects of length 0 or 1 are sorted. Otherwise, the result will be NA except for atomic vectors and objects with an S3 class (where the `>=` or `>` method is used to compare `x[i]` with `x[i-1]` for `i` in `2:length(x)`) or with an S4 class where you have to provide a method for `is.unsorted()`.

Note

This function is designed for objects with one-dimensional indices, as described above. Data frames, matrices and other arrays may give surprising results.

See Also

[sort](#), [order](#).

ISOdatetime	<i>Date-time Conversion Functions from Numeric Representations</i>
-------------	--

Description

Convenience wrappers to create date-times from numeric representations.

Usage

```
ISOdatetime(year, month, day, hour, min, sec, tz = "")
ISOdate(year, month, day, hour = 12, min = 0, sec = 0, tz = "GMT")
```

Arguments

year, month, day	numerical values to specify a day.
hour, min, sec	numerical values for a time within a day. Fractional seconds are allowed.
tz	a time zone specification to be used for the conversion. "" is the current time zone and "GMT" is UTC. Invalid values are most commonly treated as UTC, on some platforms with a warning.

Details

`ISOdatetime` and `ISOdate` are convenience wrappers for `strptime` that differ only in their defaults and that `ISOdate` sets UTC as the time zone. For dates without times it would normally be better to use the `"Date"` class.

The main arguments will be recycled using the usual recycling rules.

Because these make use of `strptime`, only years in the range 0 : 9999 are accepted.

Value

An object of class `"POSIXct"`.

See Also

[DateTimeClasses](#) for details of the date-time classes; [strptime](#) for conversions from character strings.

isS4

Test for an S4 object

Description

Tests whether the object is an instance of an S4 class.

Usage

```
isS4(object)

asS4(object, flag = TRUE, complete = TRUE)
asS3(object, flag = TRUE, complete = TRUE)
```

Arguments

object	Any R object.
flag	Optional, logical: indicate direction of conversion.
complete	Optional, logical: whether conversion to S3 is completed. Not usually needed, but see the details section.

Details

Note that `isS4` does not rely on the **methods** package, so in particular it can be used to detect the need to [require](#) that package.

`asS3` uses the value of `complete` to control whether an attempt is made to transform `object` into a valid object of the implied S3 class. If `complete` is `TRUE`, then an object from an S4 class extending an S3 class will be transformed into an S3 object with the corresponding S3 class (see [S3Part](#)). This includes classes extending the pseudo-classes `array` and `matrix`: such objects will have their class attribute set to `NULL`.

`isS4` is [primitive](#).

Value

`isS4` always returns `TRUE` or `FALSE` according to whether the internal flag marking an S4 object has been turned on for this object.

`asS4` and `asS3` will turn this flag on or off, and `asS3` will set the class from the objects `.S3Class` slot if one exists. Note that `asS3` will *not* turn the object into an S3 object unless there is a valid conversion; that is, an object of type other than `"S4"` for which the S4 object is an extension, unless argument `complete` is `FALSE`.

See Also

[is.object](#) for a more general test; [Introduction](#) for general information on S4; [Classes_Details](#) for more on S4 class definitions.

Examples

```
isS4(pi) # FALSE
isS4(getClass("MethodDefinition")) # TRUE
```

`isSymmetric`

Test if a Matrix or other Object is Symmetric (Hermitian)

Description

Generic function to test if `object` is symmetric or not. Currently only a matrix method is implemented, where a [complex](#) matrix `Z` must be “Hermitian” for `isSymmetric(Z)` to be true, and (since R >= 4.5.0), `isSymmetric(Z, trans = "T")` checks for “simple” symmetry.

Usage

```
isSymmetric(object, ...)
## S3 method for class 'matrix'
isSymmetric(object, tol = 100 * .Machine$double.eps,
             toll = 8 * tol, trans = "C", ...)
```

Arguments

<code>object</code>	any R object; a <code>matrix</code> for the matrix method.
<code>tol</code>	numeric scalar ≥ 0 . Smaller differences are not considered, see <code>all.equal.numeric</code> .
<code>tol1</code>	numeric scalar ≥ 0 . <code>isSymmetric.matrix()</code> ‘pre-tests’ the first and last few rows for fast detection of ‘obviously’ asymmetric cases with this tolerance. Setting it to length zero will skip the pre-tests.
<code>trans</code>	a single <code>character</code> , only relevant for a <code>complex</code> matrix <code>Z</code> : if it is "C" (as by default), <code>Conj(t(Z))</code> must be the same as <code>Z</code> whereas otherwise (typically it is "T") <code>t(Z)</code> must equal <code>Z</code> . The argument name is inherited from LAPACK.
<code>...</code>	further arguments passed to methods; the matrix method passes these to <code>all.equal</code> . If the row and column names of <code>object</code> are allowed to differ for the symmetry check do use <code>check.attributes = FALSE</code> !

Details

The `matrix` method is used inside `eigen` by default to test symmetry of matrices *up to rounding error*, using `all.equal`. It might not be appropriate in all situations.

Note that a matrix `m` is only symmetric if its `rownames` and `colnames` are identical. Consider using `unname(m)`.

Value

logical indicating if `object` is symmetric or not.

See Also

`eigen` which calls `isSymmetric` when its `symmetric` argument is missing.

Examples

```
isSymmetric(D3 <- diag(3)) # -> TRUE

D3[2, 1] <- 1e-100
D3
isSymmetric(D3) # TRUE
isSymmetric(D3, tol = 0) # FALSE for zero-tolerance

## Complex Matrices - Hermitian or not
z <- sqrt(matrix(-1:2 + 0i, 2)); Z <- t(Conj(z)) %*% z
ZtZ <- t(z) %*% z
Z ; ZtZ
isSymmetric(Z) # TRUE
isSymmetric(Z + 1) # TRUE
isSymmetric(Z + 1i) # FALSE -- a Hermitian matrix has a *real* diagonal

colnames(D3) <- c("X", "Y", "Z")
isSymmetric(D3) # FALSE (as row and column names differ)
isSymmetric(D3, check.attributes=FALSE) # TRUE (as names are not checked)
```

jitter

*'Jitter' (Add Noise) to Numbers***Description**

Add a small amount of noise (“jitter”) to a numeric vector.

Usage

```
jitter(x, factor = 1, amount = NULL)
```

Arguments

<code>x</code>	numeric vector to which <i>jitter</i> should be added.
<code>factor</code>	numeric; used in calculation of <code>amount</code> when the provided <code>amount</code> is 0 or <code>NULL</code> .
<code>amount</code>	number or <code>NULL</code> ; when positive, specifies the amount of jitter; see Details, also for other cases.

Details

The result of `r <- x + amount * runif(n, -1, 1)` where `n <- length(x)`.

When `amount` is `NULL` (the default) `amount <- factor * d/5` where *d* is about the smallest difference between adjacent unique (up to fuzz) `x` values.

If `amount == 0`, `amount <- factor * (max(x) - min(x)) / 50`, (using only finite `x` values), which is the same as in S and the references. In the above cases, the final `amount` is always ensured to be positive.

The short `jitter()` function is itself a succinct definition.

Value

`jitter(x, ...)` returns a numeric of the same length as `x`, but with an `amount` of noise added in order to break ties.

[rug](#) which you may want to combine with `jitter`.

Examples

```
round(jitter(c(rep(1, 3), rep(1.2, 4), rep(3, 3))), 3)
## These two had failed with S-plus 3.x: max(x) - min(x) == 0
jitter(rep(0, 7))
jitter(rep(10000, 5))
```

kappa

Compute or Estimate the Condition Number of a Matrix

Description

The condition number of a regular (square) matrix is the product of the *norm* of the matrix and the norm of its inverse (or pseudo-inverse), and hence depends on the kind of matrix-norm.

`kappa()` computes by default (an estimate of) the 2-norm condition number of a matrix or of the *R* matrix of a *QR* decomposition, perhaps of a linear fit. The 2-norm condition number can be shown to be the ratio of the largest to the smallest *non-zero* singular value of the matrix.

`rcond()` computes an approximation of the reciprocal **condition** number, see the details.

Usage

```
kappa(z, ...)
## Default S3 method:
kappa(z, exact = FALSE,
      norm = NULL, method = c("qr", "direct"),
      inv_z = solve(z),
      triangular = FALSE, uplo = "U", ...)

## S3 method for class 'lm'
kappa(z, ...)
## S3 method for class 'qr'
kappa(z, ...)

.kappa_tri(z, exact = FALSE, LINPACK = TRUE, norm = NULL, uplo = "U", ...)

rcond(x, norm = c("O", "I", "1"), triangular = FALSE, uplo = "U", ...)
```

Arguments

<code>z, x</code>	a numeric or complex matrix or a result of <code>qr</code> or a fit from a class inheriting from "lm".
<code>exact</code>	logical. Should the result be exact (up to small rounding error) as opposed to fast (but quite inaccurate)?
<code>norm</code>	character string, specifying the matrix norm with respect to which the condition number is to be computed, see the function <code>norm()</code> . For <code>kappa()</code> , the default is "2", for <code>rcond()</code> it is "O", and for <code>.kappa_tri()</code> , the default depends on <code>exact</code> : if that is true, the default is "2", otherwise "O", meaning the One- or 1-norm. For <code>exact=FALSE</code> , the currently only other possible value is "I" for the infinity norm. For <code>exact=TRUE</code> , <code>norm</code> may be "2", or any of the possible type values in <code>norm(., type = *)</code> .

<code>method</code>	a partially matched character string specifying the method to be used; "qr" is the default for back-compatibility, mainly.
<code>inv_z</code>	for <code>exact=TRUE</code> , <code>norm != "2"</code> , (an approximation of) <code>solve(z)</code> ; could be the pseudo inverse or a fast approximate inverse of the matrix <code>z</code> . By default, <code>solve(z)</code> is the most expensive part of the condition computation when <code>exact</code> is true.
<code>triangular</code>	logical. If true, the matrix used is just the upper or lower triangular part of <code>z</code> (or <code>x</code>), depending on
<code>uplo</code>	character string, either "U" or "L". Used only when <code>triangular = TRUE</code> , indicates if the upper or lower triangular part of the matrix is to be used.
<code>LINPACK</code>	logical. If true and <code>z</code> is not complex, the LINPACK routine <code>dtrco()</code> is called; otherwise the relevant LAPACK routine is.
<code>...</code>	further arguments passed to or from other methods; for <code>kappa.*()</code> , notably LINPACK when <code>norm</code> is not "2".

Details

For `kappa()`, if `exact = FALSE` (the default) the condition number is estimated by a cheap approximation to the 1-norm of the triangular matrix R of the `qr(x)` decomposition $z = QR$. However, the exact 2-norm calculation (via `svd`) is also likely to be quick enough.

Note that the approximate 1- and Inf-norm condition numbers via `method = "direct"` are much faster to calculate, and `rcond()` computes these *reciprocal* condition numbers, also for complex matrices, using standard LAPACK routines. Currently, also the `kappa*()` functions compute these approximations whenever `exact` is false, i.e., by default.

`kappa` and `rcond` are different interfaces to *partly* identical functionality.

`.kappa_tri` is an internal function called by `kappa.qr` and `kappa.default`; `tri` is for *triangular* and its methods only consider the upper or lower triangular part of the matrix, depending on `uplo = "U"` or `"L"`, where `"U"` was internally hard wired before R 4.4.0.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The condition number, *kappa*, or an approximation if `exact = FALSE`.

Author(s)

The design was inspired by (but differs considerably from) the `S` function of the same name described in Chambers (1992).

kappa(A) # -> Inf
kappa(A, exact=TRUE) # 8.675057e+15 ( 2-norm )

## now for the 1-norm :
try(kappa(A, exact=TRUE, norm = "1")) #-> Error: computationally singular
try(kappa(A, exact=TRUE, norm = "1",
          inv_z = solve(A, tol = 1e-19))) # 5.22057e16 on x86_64 Linux with GCC

```

kronecker

Kronecker Products on Arrays

Description

Computes the generalised Kronecker product of two arrays, X and Y.

Usage

```

kronecker(X, Y, FUN = "*", make.dimnames = FALSE, ...)
X %x% Y

```

Arguments

X	a vector or array.
Y	a vector or array.
FUN	a function; it may be a quoted string.

```

make.dimnames
      logical: provide dimnames that are the product of the dimnames of X and Y.
...
      optional arguments to be passed to FUN.

```

Details

If X and Y do not have the same number of dimensions, the smaller array is padded with dimensions of size one. The returned array comprises submatrices constructed by taking X one term at a time and expanding that term as `FUN(x, Y, ...)`.

`%x%` is an alias for `kronecker` (where `FUN` is hardwired to `"*"`).

Value

An array A with dimensions `dim(X) * dim(Y)`.

Examples

```

# simple scalar multiplication
( M <- matrix(1:6, ncol = 2) )
kronecker(4, M)
# Block diagonal matrix:
kronecker(diag(1, 3), M)

# ask for dimnames

fred <- matrix(1:12, 3, 4, dimnames = list(LETTERS[1:3], LETTERS[4:7]))
bill <- c("happy" = 100, "sad" = 1000)
kronecker(fred, bill, make.dimnames = TRUE)

bill <- outer(bill, c("cat" = 3, "dog" = 4))
kronecker(fred, bill, make.dimnames = TRUE)

```

l10n_info

Localization Information

Description

Report on localization information.

Usage

```
l10n_info()
```

Details

‘A Latin-1 locale’ includes supersets (for printable characters) such as Windows codepage 1252 but not Latin-9 (ISO 8859-15).

On **Windows** (where the resulting list contains `codepage` and `system.codepage` components additionally), common codepages are 1252 (Western European), 1250 (Central European), 1251 (Cyrillic), 1253 (Greek), 1254 (Turkish), 1255 (Hebrew), 1256 (Arabic), 1257 (Baltic), 1258 (Vietnamese), 874 (Thai), 932 (Japanese), 936 (Simplified Chinese), 949 (Korean) and 950 (Traditional Chinese). Codepage 28605 is Latin-9 and 65001 is UTF-8 (where supported). R does not allow the C locale, and uses 1252 as the default codepage.

Value

A list with three logical elements and further OS-specific elements:

<code>MBCS</code>	If a multi-byte character set in use?
<code>UTF-8</code>	Is this known to be a UTF-8 locale?
<code>Latin-1</code>	Is this known to be a Latin-1 locale?

Not on Windows:

<code>codeset</code>	character. The encoding name as reported by the OS, possibly "". (Added in R 4.1.0. Encoding names are OS-specific.)
----------------------	--

Only on Windows:

<code>codepage</code>	integer: the Windows codepage corresponding to the locale R is using (and not necessarily that Windows is using).
<code>system.codepage</code>	integer: the Windows system/ANSI codepage (the codepage Windows is using). Added in R 4.1.0.

```

labels

Find Labels from Object

Description

Find a suitable set of labels from an object for use in printing or plotting, for example. A generic function.

Usage

```
labels(object, ...)
```

Arguments

`object` any R object: the function is generic.
`...` further arguments passed to or from other methods.

Value

A character vector or list of such vectors. For a vector the results is the names or `seq_along(x)` and for a data frame or array it is the `dimnames` (with `NULL` expanded to `seq_len(d[i])`).

References

Chambers JM, Hastie TJ (1992). *Statistical Models in S*. Chapman & Hall, London. ISBN 9780412830402.

lapply

*Apply a Function over a List or Vector***Description**

`lapply` returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

`sapply` is a user-friendly version and wrapper of `lapply` by default returning a vector, matrix or, if `simplify = "array"`, an array if appropriate, by applying `simplify2array()`. `sapply(x, f, simplify = FALSE, USE.NAMES = FALSE)` is the same as `lapply(x, f)`.

`vapply` is similar to `sapply`, but has a pre-specified type of return value, so it can be safer (and sometimes faster) to use.

`replicate` is a wrapper for the common use of `sapply` for repeated evaluation of an expression (which will usually involve random number generation).

`simplify2array()` is the utility called from `sapply()` when `simplify` is not false and is similarly called from `mapply()`.

Usage

```
lapply(X, FUN, ...)

sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)

vapply(X, FUN, FUN.VALUE, ..., USE.NAMES = TRUE)

replicate(n, expr, simplify = "array")

simplify2array(x, higher = TRUE, except = c(0L, 1L))
```

Arguments

<code>X</code>	a vector (atomic or list) or an expression object. Other objects (including classed objects) will be coerced by <code>base::as.list</code> .
<code>FUN</code>	the function to be applied to each element of <code>X</code> ; see ‘Details’. In the case of functions like <code>+</code> , <code>%*%</code> , the function name must be backquoted or quoted.
<code>...</code>	optional arguments to <code>FUN</code> .
<code>simplify</code>	logical or character string; should the result be simplified to a vector, matrix or higher dimensional array if possible? For <code>sapply</code> it must be named and not abbreviated. The default value, <code>TRUE</code> , returns a vector or matrix if appropriate, whereas if <code>simplify = "array"</code> the result may be an array of “rank” (<code>=length(dim(.))</code>) one higher than the result of <code>FUN(X[[i]])</code> .
<code>USE.NAMES</code>	logical; if <code>TRUE</code> and if <code>X</code> is character, use <code>X</code> as names for the result unless it had names already. Since this argument follows <code>...</code> its name cannot be abbreviated.
<code>FUN.VALUE</code>	a (generalized) vector; a template for the return value from <code>FUN</code> . See ‘Details’.
<code>n</code>	integer: the number of replications.
<code>expr</code>	the expression (a language object , usually a call) to evaluate repeatedly.
<code>x</code>	a list, typically returned from <code>lapply()</code> .
<code>higher</code>	logical; if <code>true</code> , <code>simplify2array()</code> will produce a (“higher rank”) array when appropriate, whereas <code>higher = FALSE</code> would return a matrix (or vector) only. These two cases correspond to <code>sapply(*, simplify = "array")</code> or <code>simplify = TRUE</code> , respectively.
<code>except</code>	integer vector or <code>NULL</code> ; the default <code>c(0L, 1L)</code> corresponds to the exceptions used by <code>sapply</code> : a list with elements of common length 0 or 1 is not simplified to an array but is returned, respectively, as is or unlisted. These exceptions can be disabled by specifying only a subset of <code>0:1</code> , or <code>NULL</code> to always simplify to an array (if possible).

Details

`FUN` is found by a call to `match.fun` and typically is specified as a function or a symbol (e.g., a backquoted name) or a character string specifying a function to be searched for from the environment of the call to `lapply`.

Function `FUN` must be able to accept as input any of the elements of `X`. If the latter is an atomic vector, `FUN` will always be passed a length-one vector of the same type as `X`.

Arguments in `...` cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to `FUN`. In general-purpose code it is good practice to name the first two arguments `X` and `FUN` if `...` is passed through: this both avoids partial matching to `FUN` and ensures that a sensible error message is given if arguments named `X` or `FUN` are passed through `...`.

Simplification in `sapply` is only attempted if `X` has length greater than zero and if the return values from all elements of `X` are all of the same (positive) length. If the common length is one the result is a vector, and if greater than one is a matrix with a column corresponding to each element of `X`.

Simplification is always done in `vapply`. This function checks that all values of `FUN` are compatible with the `FUN.VALUE`, in that they must have the same length and type. (Types may be promoted to a higher type within the ordering `logical < integer < double < complex`, but not demoted.)

Users of S4 classes should pass a list to `lapply` and `vapply`: the internal coercion is done by the `as.list` in the base namespace and not one defined by a user (e.g., by setting S4 methods on the base function).

Value

For `lapply`, `sapply(simplify = FALSE)` and `replicate(simplify = FALSE)`, a list.

For `sapply(simplify = TRUE)` and `replicate(simplify = TRUE)`: if `X` has length zero or `n = 0`, an empty list. Otherwise an atomic vector or matrix or list of the same length as `X` (of length `n` for `replicate`). If simplification occurs, the output type is determined from the highest type of the return values in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`, after coercion of pairlists to lists.

`vapply` returns a vector or array of type matching the `FUN.VALUE`. If `length(FUN.VALUE) == 1` a vector of the same length as `X` is returned, otherwise an array. If `FUN.VALUE` is not an `array`, the result is a matrix with `length(FUN.VALUE)` rows and `length(X)` columns, otherwise an array `a` with `dim(a) == c(dim(FUN.VALUE), length(X))`.

The (Dim)names of the array value are taken from the `FUN.VALUE` if it is named, otherwise from the result of the first function call. Column names of the matrix or more generally the names of the last dimension of the array value or names of the vector value are set from `X` as in `sapply`.

Note

`sapply(*, simplify = FALSE, USE.NAMES = FALSE)` is equivalent to `lapply(*)`.

For historical reasons, the calls created by `lapply` are unevaluated, and code has been written (e.g., `bquote`) that relies on this. This means that the recorded call is always of the form `FUN(X[[i]], ...)`, with `i` replaced by the current (integer or double) index. This is not normally a problem, but it can be if `FUN` uses `sys.call` or `match.call` or if it is a primitive function that makes use of the call. This means that it is often safer to call primitive functions with a wrapper, so that e.g. `lapply(1:1, function(x) is.numeric(x))` is required to ensure that method dispatch for `is.numeric` occurs correctly.

If `expr` is a function call, be aware of assumptions about where it is evaluated, and in particular what `...` might refer to. You can pass additional named arguments to a function call as additional named arguments to `replicate`: see ‘Examples’.

Examples

```
require(stats); require(graphics)

x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE,FALSE,FALSE,TRUE))
# compute the list mean for each list element
lapply(x, mean)
# median and quartiles for each list element
lapply(x, quantile, probs = 1:3/4)
sapply(x, quantile)
i39 <- sapply(3:9, seq) # list of vectors
sapply(i39, fivenum)
```

```
vapply(i39, fivenum,
      c(Min. = 0, "1st Qu." = 0, Median = 0, "3rd Qu." = 0, Max. = 0))

## sapply(*, "array") -- artificial example
(v <- structure(10*(5:8), names = LETTERS[1:4]))
f2 <- function(x, y) outer(rep(x, length.out = 3), y)
(a2 <- sapply(v, f2, y = 2*(1:5), simplify = "array"))
a.2 <- vapply(v, f2, outer(1:3, 1:5), y = 2*(1:5))
stopifnot(dim(a2) == c(3,5,4), all.equal(a2, a.2),
          identical(dimnames(a2), list(NULL,NULL,LETTERS[1:4])))

hist(replicate(100, mean(rexp(10))))

## use of replicate() with parameters:
foo <- function(x = 1, y = 2) c(x, y)
# does not work: bar <- function(n, ...) replicate(n, foo(...))
bar <- function(n, x) replicate(n, foo(x = x))
bar(5, x = 3)
```

Last.value

Value of Last Evaluated Expression

Description

The value of the internal evaluation of a top-level R expression is always assigned to `.Last.value` (in `package:base`) before further processing (e.g., printing).

Usage

```
.Last.value
```

Details

The value of a top-level assignment *is* put in `.Last.value`, unlike `S`.

Do not assign to `.Last.value` in the workspace, because this will always mask the object of the same name in `package:base`.

See Also

[eval](#)

Examples

```
## These will not work correctly from example(),
## but they will in make check or if pasted in,
## as example() does not run them at the top level
gamma(1:15)          # think of some intensive calculation...
fac14 <- .Last.value # keep them

library("splines") # returns invisibly
.Last.value       # shows what library(.) above returned
```

La_library

LAPACK Library

Description

Report the name of the shared object file with LAPACK implementation in use.

Usage

```
La_library()
```

Value

A character vector of length one ("" when the name is not known). The value can be used as an indication of which LAPACK implementation is in use. Typically, the R version of LAPACK will appear as `libRlapack.so` (`libRlapack.dylib`), depending on how R was built. Note that `libRlapack.so` (`libRlapack.dylib`) may also be shown for an external LAPACK implementation that had been copied, hard-linked or renamed by the system administrator. Otherwise, the shared object file will be given and its path/name may indicate the vendor/version.

The detection does not work on Windows, nor for the Accelerate framework on macOS, nor in the rare (and unsupported) case of a static external library.

It is possible to build R against an enhanced BLAS which contains some but not all LAPACK routines, in which case this function reports the library containing routine `ILAVER`.

See Also

[extSoftVersion](#) for versions of other third-party software including BLAS.

[La_version](#) for the version of LAPACK in use.

Examples

```
La_library()
```

La_version

LAPACK Version

Description

Report the version of LAPACK in use.

Usage

```
La_version()
```

Value

A character vector of length one.

Note that this is the version as reported by the library at runtime. It may differ from the reference ('netlib') implementation, for example by having some optimized or patched routines. For the version included with R, the older (not Fortran 90) versions of

```
DLARTG DLASSQ ZLARTG ZLASSQ
```

are used.

See Also

[extSoftVersion](#) for versions of other third-party software.

[La_library](#) for binary/executable file with LAPACK in use.

Examples

```
La_version()
```

length	<i>Length of an Object</i>
--------	----------------------------

Description

Get or set the length of vectors (including lists) and factors, and of any other R object for which a method has been defined.

Usage

```
length(x)
length(x) <- value
```

Arguments

x	an R object. For replacement, a vector or factor.
value	a non-negative integer or double (which will be rounded down).

Details

Both functions are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). `length<-` has a "factor" method.

The replacement form can be used to reset the length of a vector. If a vector is shortened, extra values are discarded and when a vector is lengthened, it is padded out to its new length with NAs for atomic vectors but by `nul`, i.e., `as.raw(0)` for [raw](#) vectors, whereas [list](#) and [expression](#) vectors use `NULL`, the latter three cases in line with vector creation by `vector("<mode>", length)`.

Both are [primitive](#) functions.

Value

The default method for `length` currently returns a non-negative [integer](#) of length 1, except for vectors of more than $2^{31} - 1$ elements, when it returns a double.

For vectors (including lists and expressions) and factors the length is the number of elements. For an environment it is the number of objects in the environment, and `NULL` has length 0. For expressions and pairlists (including [language objects](#) and dot-dot-dot lists) it is the length of the pairlist chain. All other objects (including functions) have length one: note that for functions this differs from `S`.

The replacement form removes all the attributes of `x` except its names, which are adjusted (and if necessary extended by `" "`).

Warning

Package authors have written methods that return a result of length other than one (**Formula**) and that return a vector of type [double](#) (**Matrix**), even with non-integer values (earlier versions of **sets**). Where a single double value is returned that can be represented as an integer it is returned as a length-one integer vector.

See Also

`nchar` for counting the number of characters in character vectors, [lengths](#) for getting the length of every element in a list.

Examples

```
length(diag(4)) # = 16 (4 x 4)
length(options()) # 12 or more
length(y ~ x1 + x2 + x3) # 3
length(expression(x, {y <- x^2; y+2}, x^y)) # 3

## from example(warbreaks)
require(stats)

fm1 <- lm(breaks ~ wool * tension, data = warbreaks)
length(fm1$call) # 3, lm() and two arguments.
length(formula(fm1)) # 3, ~ lhs rhs
```

lengths

Lengths of List or Vector Elements

Description

Get the length of each element of a [list](#) or atomic vector (`is.atomic`) as an integer or numeric vector.

Usage

```
lengths(x, use.names = TRUE)
```

Arguments

<code>x</code>	a list , list-like such as an expression , <code>NULL</code> or an atomic vector (for which the result is trivial).
<code>use.names</code>	logical indicating if the result should inherit the names from <code>x</code> .

Details

This function loops over `x` and returns a compatible vector containing the length of each element in `x`. Effectively, `length(x[[i]])` is called for all `i`, so any methods on `length` are considered.

`lengths` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Value

A non-negative [integer](#) of length `length(x)`, except when any element has a length of more than $2^{31} - 1$ elements, when it returns a double vector. When `use.names` is true, the names are taken from the names on `x`, if any. The result has the same dimensions as `x`.

Note

One raison d'être of `lengths(x)` is its use as a more efficient version of `sapply(x, length)` and similar `*apply` calls to [length](#). This is the reason why `x` may be an atomic vector, even though `lengths(x)` is trivial in that case.

See Also

[length](#) for getting the length of any R object.

Examples

```
require(stats)
## summarize by month
l <- split(airquality$Ozone, airquality$Month)
avgOz <- lapply(l, mean, na.rm=TRUE)
## merge result
airquality$avgOz <- rep(unlist(avgOz, use.names=FALSE), lengths(l))
## but this is safer and cleaner, but can be slower
airquality$avgOz <- unsplit(avgOz, airquality$Month)

## should always be true, except when a length does not fit in 32 bits
## or l has dimensions
stopifnot(identical(lengths(l), vapply(l, length, integer(1L))))

## empty lists are not a problem
x <- list()
stopifnot(identical(lengths(x), integer()))

## nor are "list-like" expressions:
lengths(expression(u, v, 1+ 0:9))

## and we should dispatch to length methods
f <- c(rep(1, 3), rep(2, 6), 3)
dates <- split(as.POSIXlt(Sys.time() + 1:10), f)
stopifnot(identical(lengths(dates), vapply(dates, length, integer(1L))))
```

levels

*Levels Attributes***Description**

`levels` provides access to the levels attribute of a variable. The first form returns the value of the levels of its argument and the second sets the attribute.

Usage

```
levels(x)
levels(x) <- value
```

Arguments

<code>x</code>	an object, for example a factor.
<code>value</code>	a valid value for <code>levels(x)</code> . For the default method, <code>NULL</code> or a character vector. For the <code>factor</code> method, a vector of character strings with length at least the number of levels of <code>x</code> , or a named list specifying how to rename the levels.

Details

Both the extractor and replacement forms are generic and new methods can be written for them. The most important method for the replacement function is that for [factors](#).

For the factor replacement method, a `NA` in `value` causes that level to be removed from the levels and the elements formerly with that level to be replaced by `NA`.

Note that for a factor, replacing the levels via `levels(x) <- value` is not the same as (and is preferred to) `attr(x, "levels") <- value`.

The replacement function is [primitive](#).

[nlevels](#), [relevel](#), [reorder](#).

Examples

```
## assign individual levels
x <- gl(2, 4, 8)
levels(x)[1] <- "low"
levels(x)[2] <- "high"
x

## or as a group
y <- gl(2, 4, 8)
levels(y) <- c("low", "high")
```

```

y

## combine some levels
z <- gl(3, 2, 12, labels = c("apple", "salad", "orange"))
z
levels(z) <- c("fruit", "veg", "fruit")
z

## same, using a named list
z <- gl(3, 2, 12, labels = c("apple", "salad", "orange"))
z
levels(z) <- list("fruit" = c("apple", "orange"),
                 "veg"    = "salad")
z

## we can add levels this way:
f <- factor(c("a", "b"))
levels(f) <- c("c", "a", "b")
f

f <- factor(c("a", "b"))
levels(f) <- list(C = "C", A = "a", B = "b")
f

```

libcurlVersion	<i>Report Version of libcurl</i>
----------------	----------------------------------

Description

Report version of libcurl in use.

Usage

```
libcurlVersion()
```

Value

A character string, with value the libcurl version in use or "" if none is. If libcurl is available, has attributes

ssl_version A character string naming the SSL/TLS implementation and version, possibly "none". It is intended for the version of OpenSSL used, but not all implementations of libcurl use OpenSSL — for example macOS reports "SecureTransport", its wrapper for SSL/TLS.

libssh_version A character string naming the libssh version, which may or may not be available (it is used for e.g. scp and sftp protocols). Where present, something like "libssh2/1.5.0".

protocols A character vector of the names of supported protocols, also known as ‘schemes’ when part of a URL.

Warning

In late 2017 a libcurl installation was seen divided into two libraries, libcurl and libcurl-feature, and the first had been updated but not the second. As the compiled function recording the version was in the latter, the version reported by libcurlVersion was misleading.

See Also

`extSoftVersion` for versions of other third-party software.
`curlGetHeaders`, `download.file` and `url` for functions which (optionally) use libcurl.
<https://curl.se/docs/sslcerts.html> and <https://curl.se/docs/ssl-compared.html> for more details on SSL versions (the current standard being known as TLS). Normally libcurl used with R uses SecureTransport on macOS, OpenSSL on Windows and GnuTLS, NSS or OpenSSL on Unix-alikes. (At the time of writing Debian-based Linuxen use GnuTLS and RedHat-based ones use OpenSSL, having previously used NSS.)

Examples

```
libcurlVersion()
```

libPaths

Search Paths for Packages

Description

`.libPaths` gets/sets the library trees within which packages are looked for.

Usage

```
.libPaths(new, include.site = TRUE)

.Library
.Library.site
```

Arguments

<code>new</code>	a character vector with the locations of R library trees. Tilde expansion (<code>path.expand</code>) is done, and if any element contains one of <code>*?[]</code> , globbing is done where supported by the platform: see <code>Sys.glob</code> .
<code>include.site</code>	a logical value indicating whether the value of <code>.Library.site</code> should be included in the new set of library tree locations. Defaulting to <code>TRUE</code> , it is ignored when <code>.libPaths</code> is called without the <code>new</code> argument.

Details

`.Library` is a character string giving the location of the default library, the ‘library’ subdirectory of [R_HOME](#).

`.Library.site` is a (possibly empty) character vector giving the locations of the site libraries.

`.libPaths` is used for getting or setting the library trees that R knows about and hence uses when looking for packages (the library search path). If called with argument `new`, by default, the library search path is set to the existing directories in `unique(c(new, .Library.site,`

`.Library()`) and this is returned. If `include.site` is `FALSE` when the `new` argument is set, `.Library.site` is not added to the new library search path. If called without the `new` argument, a character vector with the currently active library trees is returned.

How paths in `new` with a trailing slash are treated is OS-dependent. On a POSIX filesystem existing directories can usually be specified with a trailing slash. On Windows filepaths with a trailing slash (or backslash) are invalid and existing directories specified with a trailing slash may not be added to the library search path.

At startup, the library search path is initialized from the environment variables `R_LIBS`, `R_LIBS_USER` and `R_LIBS_SITE`, which if set should give lists of directories where R library trees are rooted, colon-separated on Unix-like systems and semicolon-separated on Windows. For the latter two, a value of `NULL` indicates an empty list of directories. (Note that as from R 4.2.0, both are set by R start-up code if not already set or empty so can be interrogated from an R session to find their defaults: in earlier versions this was true only for `R_LIBS_USER`.)

First, `.Library.site` is initialized from `R_LIBS_SITE`. If this is unset or empty, the ‘`site-library`’ subdirectory of `R_HOME` is used. Only directories which exist at the time of initialization are retained. Then, `.libPaths()` is called with the combination of the directories given by `R_LIBS` and `R_LIBS_USER`. By default `R_LIBS` is unset, and if `R_LIBS_USER` is unset or empty, it is set to directory ‘`R/R.version$platform-library/x.y`’ of the home directory on Unix-like systems (or ‘`Library/R/m/x.y/library`’ for CRAN macOS builds, with `m Sys.info()[ "machine" ]`) and ‘`R/win-library/x.y`’ subdirectory of `LOCALAPPDATA` on Windows, for R `x.y.z`.

Both `R_LIBS_USER` and `R_LIBS_SITE` feature possible expansion of specifiers for R-version-specific information as part of the startup process. The possible conversion specifiers all start with a ‘`%`’ and are followed by a single letter (use ‘`%%`’ to obtain ‘`%`’), with currently available conversion specifications as follows:

- ‘`%V`’ R version number including the patch level (e.g., ‘`2.5.0`’).
- ‘`%v`’ R version number excluding the patch level (e.g., ‘`2.5`’).
- ‘`%p`’ the platform for which R was built, the value of `R.version$platform`.
- ‘`%o`’ the underlying operating system, the value of `R.version$os`.
- ‘`%a`’ the architecture (CPU) R was built on/for, the value of `R.version$arch`.

(See [version](#) for details on R version information.) In addition, ‘`%U`’ and ‘`%S`’ expand to the R defaults for, respectively, `R_LIBS_USER` and `R_LIBS_SITE`.

Function `.libPaths` always uses the values of `.Library` and `.Library.site` in the base namespace. `.Library.site` can be set by the `site` in ‘`Rprofile.site`’, which should be followed by a call to `.libPaths(.libPaths())` to make use of the updated value.

For consistency, the paths are always normalized by `normalizePath(winslash = "/")`.

`LOCALAPPDATA` (usually `C:\Users\username\AppData\Local`) on Windows is a hidden directory and may not be viewed by some software. It may be opened by `shell.exec(Sys.getenv("LOCALAPPDATA"))`.

Value

A character vector of file paths.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also[library](#)**Examples**

```
.libPaths() # all library trees R knows about
```

library

*Loading/Attaching and Listing of Packages***Description**

`library` and `require` load and attach add-on packages.

Usage

```
library(package, help, pos = 2, lib.loc = NULL,
        character.only = FALSE, logical.return = FALSE,
        warn.conflicts, quietly = FALSE,
        verbose = getOption("verbose"),
        mask.ok, exclude, include.only,
        attach.required = missing(include.only))
```

```
require(package, lib.loc = NULL, quietly = FALSE,
        warn.conflicts,
        character.only = FALSE,
        mask.ok, exclude, include.only,
        attach.required = missing(include.only))
```

```
conflictRules(pkg, mask.ok = NULL, exclude = NULL)
```

Arguments

`package, help` the name of a package, given as a [name](#) or literal character string, or a character string, depending on whether `character.only` is `FALSE` (default) or `TRUE`.

`pos` the position on the search list at which to attach the loaded namespace. Can also be the name of a position on the current search list as given by [search\(\)](#).

`lib.loc` a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known to [.libPaths\(\)](#). Non-existent library trees are silently ignored.

`character.only` a logical indicating whether `package` or `help` can be assumed to be character strings.

`logical.return` logical. If it is `TRUE`, `FALSE` or `TRUE` is returned to indicate success.

`warn.conflicts` logical. If `TRUE`, warnings are printed about [conflicts](#) from attaching the new package. A conflict is a function masking a function, or a non-function masking a non-function. The default is `TRUE` unless specified as `FALSE` in the `conflicts.policy` option.

<code>verbose</code>	a logical. If <code>TRUE</code> , additional diagnostics are printed.
<code>quietly</code>	a logical. If <code>TRUE</code> , no message confirming package attaching is printed, and most often, no errors/warnings are printed if package attaching fails.
<code>pkg</code>	character string naming a package.
<code>mask.ok</code>	character vector of names of objects that can mask objects on the search path without signaling an error when strict conflict checking is enabled.
<code>exclude, include.only</code>	character vector of names of objects to exclude or include in the attached frame. Only one of these arguments may be used in a call to <code>library</code> or <code>require</code> .
<code>attach.required</code>	logical specifying whether required packages listed in the <code>Depends</code> clause of the <code>DESCRIPTION</code> file should be attached automatically.

Details

`library(package)` and `require(package)` both load the namespace of the package with name `package` and attach it on the search list. `require` is designed for use inside other functions; it returns `FALSE` and gives a warning (rather than an error as `library()` does by default) if the package does not exist. Both functions check and update the list of currently attached packages and do not reload a namespace which is already loaded. (If you want to reload such a package, call `detach(unload = TRUE)` or `unloadNamespace` first.) If you want to load a package without attaching it on the search list, see `requireNamespace`.

To suppress messages during the loading of packages use `suppressPackageStartupMessages`: this will suppress all messages from R itself but not necessarily all those from package authors.

If `library` is called with no `package` or `help` argument, it lists all available packages in the libraries specified by `lib.loc`, and returns the corresponding information in an object of class `"libraryIQR"`. (The structure of this class may change in future versions.) Use `.packages(all = TRUE)` to obtain just the names of all available packages, and `installed.packages()` for even more information.

`library(help = pkgname)` computes basic information about the package `pkgname`, and returns this in an object of class `"packageInfo"`. (The structure of this class may change in future versions.) When used with the default value (`NULL`) for `lib.loc`, the attached packages are searched before the libraries.

Value

Normally `library` returns (invisibly) the list of attached packages, but `TRUE` or `FALSE` if `logical.return` is `TRUE`. When called as `library()` it returns an object of class `"libraryIQR"`, and for `library(help=)`, one of class `"packageInfo"`.

`require` returns (invisibly) a logical indicating whether the required package is available.

Conflicts

Handling of conflicts depends on the setting of the `conflicts.policy` option. If this option is not set, then conflicts result in warning messages if the argument `warn.conflicts` is `TRUE`. If the option is set to the character string `"strict"`, then all unresolved conflicts signal errors. Conflicts can be resolved using the `mask.ok`, `exclude`, and `include.only` arguments to `library` and `require`. Defaults for `mask.ok` and `exclude` can be specified using `conflictRules`.

If the `conflicts.policy` option is set to the string `"depends.ok"` then conflicts resulting from attaching declared dependencies will not produce errors, but other conflicts will. This is likely to be the best setting for most users wanting some additional protection against unexpected conflicts.

The policy can be tuned further by specifying the `conflicts.policy` option as a named list with the following fields:

`error`: logical; if `TRUE` treat unresolved conflicts as errors.

`warn`: logical; unless `FALSE` issue a warning message when conflicts are found.

`generics.ok`: logical; if `TRUE` ignore conflicts created by defining S4 generics for functions on the search path.

`depends.ok`: logical; if `TRUE` do not treat conflicts with required packages as errors.

`can.mask`: character vector of names of packages that are allowed to be masked. These would typically be base packages attached by default.

Licenses

Some packages have restrictive licenses, and there is a mechanism to allow users to be aware of such licenses. If `getOption("checkPackageLicense") == TRUE`, then at first use of a namespace of a package with a not-known-to-be-FOSS (see below) license the user is asked to view and accept the license: a list of accepted licenses is stored in file `'~/R/licensed'`. In a non-interactive session it is an error to use such a package whose license has not already been recorded as accepted.

Free or Open Source Software (FOSS, e.g. <https://en.wikipedia.org/wiki/FOSS>) packages are determined by the same filters used by `available.packages` but applied to just the current package, not its dependencies.

There can also be a site-wide file `'R_HOME/etc/licensed.site'` of packages (one per line).

Formal methods

`library` takes some further actions when package **methods** is attached (as it is by default). Packages may define formal generic functions as well as re-defining functions in other packages (notably **base**) to be generic, and this information is cached whenever such a namespace is loaded after **methods** and re-defined functions (**implicit generics**) are excluded from the list of conflicts. The caching and check for conflicts require looking for a pattern of objects; the search may be avoided by defining an object `.noGenerics` (with any value) in the namespace. Naturally, if the package *does* have any such methods, this will prevent them from being used.

Note

`library` and `require` can only load/attach an *installed* package, and this is detected by having a `'DESCRIPTION'` file containing a `'Built:'` field.

Under Unix-alikes, the code checks that the package was installed under a similar operating system as given by `R.version$platform` (the canonical name of the platform under which R was compiled), provided it contains compiled code. Packages which do not contain compiled code can be shared between Unix-alikes, but not to other OSes because of potential problems with line endings and OS-specific help files. If sub-architectures are used, the OS similarity is not checked since the OS used to build may differ (e.g. `i386-pc-linux-gnu` code can be built on an `x86_64-unknown-linux-gnu` OS).

The package name given to `library` and `require` must match the name given in the package's `'DESCRIPTION'` file exactly, even on case-insensitive file systems such as are common on Windows and macOS.

`library.dynam`, `data`, `install.packages` and `installed.packages`; `INSTALL`,
`REMOVE`.

The initial set of packages attached is set by `options(defaultPackages=)`: see also `Startup`.

Examples

```
library()                # list all available packages
library(lib.loc = .Library) # list all packages in the default library
library(help = splines)   # documentation on package 'splines'
library(splines)         # attach package 'splines'
require(splines)         # the same
search()                 # "splines", too
detach("package:splines")

# if the package name is in a character vector, use
pkg <- "splines"
library(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep = ":"), search()))

require(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep = ":"), search()))

require(nonexistent)     # FALSE
## Not run:
## if you want to mask as little as possible, use
library(mypkg, pos = "package:base")

## End(Not run)
```

library.dynam

Loading DLLs from Packages

Description

Load the specified file of compiled code if it has not been loaded already, or unloads it.

Usage

```
library.dynam(chname, package, lib.loc,
              verbose = getOption("verbose"),
              file.ext = .Platform$dynlib.ext, ...)

library.dynam.unload(chname, libpath,
```

```

        verbose = getOption("verbose"),
        file.ext = .Platform$dynlib.ext)

.dynLibs(new)

```

Arguments

<code>chname</code>	a character string naming a DLL (also known as a dynamic shared object or library) to load.
<code>package</code>	a character vector with the name of package.
<code>lib.loc</code>	a character vector describing the location of R library trees to search through.
<code>libpath</code>	the path to the loaded package whose DLL is to be unloaded.
<code>verbose</code>	a logical value indicating whether an announcement is printed on the console before loading the DLL. The default value is taken from the <code>verbose</code> entry in the system options .
<code>file.ext</code>	the extension (including <code>'.'</code> if used) to append to the file name to specify the library to be loaded. This defaults to the appropriate value for the operating system.
<code>...</code>	additional arguments needed by some libraries that are passed to the call to dyn.load to control how the library and its dependencies are loaded.
<code>new</code>	a list of <code>"DLLInfo"</code> objects corresponding to the DLLs loaded by packages. Can be missing.

Details

See [dyn.load](#) for what sort of objects these functions handle.

`library.dynam` is designed to be used inside a package rather than at the command line, and should really only be used inside [.onLoad](#). The system-specific extension for DLLs (e.g., `'.so'` or `'.sl'` on Unix-alike systems, `'.dll'` on Windows) should not be added.

`library.dynam.unload` is designed for use in [.onUnload](#): it unloads the DLL and updates the value of `.dynLibs()`

`.dynLibs` is used for getting (with no argument) or setting the DLLs which are currently loaded by packages (using `library.dynam`).

Value

If `chname` is not specified, `library.dynam` returns an object of class `"DLLInfoList"` corresponding to the DLLs loaded by packages.

If `chname` is specified, an object of class `"DLLInfo"` that identifies the DLL and which can be used in future calls is returned invisibly. Note that the class `"DLLInfo"` has a method for `$` which can be used to resolve native symbols within that DLL.

`library.dynam.unload` invisibly returns an object of class `"DLLInfo"` identifying the DLL successfully unloaded.

`.dynLibs` returns an object of class `"DLLInfoList"` corresponding to its current value.

Warning

Do not use `dyn.unload` on a DLL loaded by `library.dynam`: use `library.dynam.unload` to ensure that `.dynLibs` gets updated. Otherwise a subsequent call to `library.dynam` will be told the object is already loaded.

Note that whether or not it is possible to unload a DLL and then reload a revised version of the same file is OS-dependent: see the ‘Value’ section of the help for `dyn.unload`.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`getLoadedDLLs` for information on "DLLInfo" and "DLLInfoList" objects.

`.onLoad`, `library`, `dyn.load`, `.packages`, `.libPaths`

`SHLIB` for how to create suitable DLLs.

Examples

```
## Which DLLs were dynamically loaded by packages?
library.dynam()

## More on library.dynam.unload() :
require(nlme)
nlme:::.onUnload # shows library.dynam.unload() call
detach("package:nlme") # by default, unload=FALSE , so,
tail(library.dynam(), 2) # nlme still there

## How to unload the DLL ?
## Best is to unload the namespace, unloadNamespace("nlme")
## If we need to do it separately which should be exceptional:
pd.file <- attr(packageDescription("nlme"), "file")
library.dynam.unload("nlme", libpath = sub("/Meta.*", '', pd.file))
tail(library.dynam(), 2) # 'nlme' is gone now
unloadNamespace("nlme") # now gives warning
```

list	<i>Lists – Generic and Dotted Pairs</i>
------	---

Description

Functions to construct, coerce and check for both kinds of R lists.

Usage

```
list(...)
pairlist(...)

as.list(x, ...)
## S3 method for class 'environment'
as.list(x, all.names = FALSE, sorted = FALSE, ...)
as.pairlist(x)

is.list(x)
is.pairlist(x)

alist(...)
```

Arguments

<code>...</code>	objects, possibly named.
<code>x</code>	object to be coerced or tested.
<code>all.names</code>	a logical indicating whether to copy all values or (default) only those whose names do not begin with a dot.
<code>sorted</code>	a logical indicating whether the names of the resulting list should be sorted (increasingly). Note that this is somewhat costly, but may be useful for comparison of environments.

Details

Almost all lists in R internally are *Generic Vectors*, whereas traditional *dotted pair* lists (as in LISP) remain available but rarely seen by users (except as [formals](#) of functions).

The arguments to `list` or `pairlist` are of the form `value` or `tag = value`. The functions return a list or dotted pair list composed of its arguments with each value either tagged or untagged, depending on how the argument was specified.

`alist` handles its arguments as if they described function arguments. So the values are not evaluated, and tagged arguments with no value are allowed whereas `list` simply ignores them. `alist` is most often used in conjunction with `formals`.

`as.list` attempts to coerce its argument to a list. For functions, this returns the concatenation of the list of formal arguments and the function body. For expressions, the list of constituent elements is returned. `as.list` is generic, and as the default method calls `as.vector(mode = "list")` for a non-list, methods for `as.vector` may be invoked. `as.list` turns a factor into a list of one-element factors, keeping `names`. Other attributes may be dropped unless the argument already is a list or expression. (This is inconsistent with functions such as `as.character` which always drop attributes, and is for efficiency since lists can be expensive to copy.)

`is.list` returns TRUE if and only if its argument is a list *or* a pairlist of length > 0. `is.pairlist` returns TRUE if and only if the argument is a pairlist (or NULL which *is* a pairlist, see below).

The `"environment"` method for `as.list` copies the name-value pairs (for names not beginning with a dot) from an environment to a named list. The user can request that all named objects are copied. Unless `sorted = TRUE`, the list is in no particular order (the order depends on the order of creation of objects and whether the environment is hashed). No enclosing environments are searched. (Objects copied are duplicated so this can be an expensive operation.) Note that there is an inverse operation, the `as.environment()` method for list objects.

An empty pairlist, `pairlist()` is the same as `NULL`. This is different from `list()`: some but not all operations will promote an empty pairlist to an empty list.

`as.pairlist` is implemented as `as.vector(x, "pairlist")`, and hence will dispatch methods for the generic function `as.vector`. Lists are copied element-by-element into a pairlist and the names of the list used as tags for the pairlist: the return value for other types of argument is undocumented.

`list`, `is.list` and `is.pairlist` are `primitive` functions.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`vector("list", length)` for creation of a list with empty components; `c`, for concatenation; `formals`. `unlist` is an approximate inverse to `as.list()`.

`'plotmath'` for the use of `list` in plot annotation.

Examples

```
require(graphics)

# create a plotting structure
pts <- list(x = cars[,1], y = cars[,2])
plot(pts)

is.pairlist(.Options) # a user-level pairlist

## "pre-allocate" an empty list of length 5
vector("list", 5)

# Argument lists
```

```
f <- function() x
# Note the specification of a "... " argument:
formals(f) <- al <- alist(x = , y = 2+3, ... = )
f
al

## environment->list coercion

el <- new.env()
el$a <- 10
el$b <- 20
as.list(el)
```

list.files	<i>List the Files in a Directory/Folder</i>
------------	---

Description

These functions produce a character vector of the names of files or directories in the named directory.

Usage

```
list.files(path = ".", pattern = NULL, all.files = FALSE,
           full.names = FALSE, recursive = FALSE,
           ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE,
           fixed = FALSE)

dir(path = ".", pattern = NULL, all.files = FALSE,
    full.names = FALSE, recursive = FALSE,
    ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE,
    fixed = FALSE)

list.dirs(path = ".", full.names = TRUE, recursive = TRUE)
```

Arguments

path	a character vector of full path names; the default corresponds to the working directory, <code>getwd()</code> . Tilde expansion (see <code>path.expand()</code>) is performed. Missing values will be ignored. Elements with a marked encoding will be converted to the native encoding (and if that fails, considered non-existent).
pattern	an optional regular expression . Only file names which match the regular expression will be returned.
all.files	a logical value. If <code>FALSE</code> , only the names of visible files are returned (following Unix-style visibility, that is files whose name does not start with a dot). If <code>TRUE</code> , all file names will be returned.
full.names	a logical value. If <code>TRUE</code> , the directory path is prepended to the file names to give a relative file path. If <code>FALSE</code> , the file names (rather than paths) are returned.
recursive	logical. Should the listing recurse into directories?
ignore.case	logical. Should pattern-matching be case-insensitive?

<code>include.dirs</code>	logical. Should subdirectory names be included in recursive listings? (They always are in non-recursive ones).
<code>no..</code>	logical. Should both "." and ".." be excluded also from non-recursive listings?
<code>fixed</code>	logical. If TRUE, treat <code>pattern</code> as a literal string to match rather than a regular expression.

Value

A character vector containing the names of the files in the specified directories (empty if there were no files). If a path does not exist or is not a directory or is unreadable it is skipped.

The files are sorted in alphabetical order, on the full path if `full.names = TRUE`.

`list.dirs` implicitly has `all.files = TRUE`, and if `recursive = TRUE`, the answer includes path itself (provided it is a readable directory).

`dir` is an alias for `list.files`.

Note

File naming conventions are platform dependent. The pattern matching works with the case of file names as returned by the OS.

On a POSIX filesystem recursive listings will follow symbolic links to directories.

Author(s)

Ross Ihaka, Brian Ripley

See Also

`file.info`, `file.access` and `files` for many more file handling functions and `file.choose` for interactive selection.

`glob2rx` to convert wildcards (as used by system file commands and shells) to regular expressions.

`Sys.glob` for wildcard expansion on file paths. `basename` and `dirname`, useful for splitting paths into non-directory (aka 'filename') and directory parts.

Examples

```
list.files(R.home())

## . is a wildcard by default.
list.files(R.home(), ".in")
## If that's not what you want, escape it or use fixed = TRUE
list.files(R.home(), "\\..in")
list.files(R.home(), ".in", fixed = TRUE)

## Only files starting with a-l or r
## Note that a-l is locale-dependent, but using case-insensitive
## matching makes it unambiguous in English locales
dir("../..", pattern = "[a-lr]", full.names = TRUE, ignore.case = TRUE)

list.dirs(R.home("doc"))
list.dirs(R.home("doc"), full.names = FALSE)
```

list2DF*Create Data Frame From List*

Description

Create a data frame from a list of variables.

Usage

```
list2DF(x = list(), nrow = 0)
```

Arguments

x	A list of same-length variables for the data frame.
nrow	An integer giving the desired number of rows for the data frame in case x gives no variables (i.e., has length zero).

Details

Note that all list elements are taken “as is”.

Value

A data frame with the given variables.

See Also

[data.frame](#)

Examples

```
## Create a data frame holding a list of character vectors and the
## corresponding lengths:
x <- list(character(), "A", c("B", "C"))
n <- lengths(x)
list2DF(list(x = x, n = n))

## Create data frames with no variables and the desired number of rows:
list2DF()
list2DF(nrow = 3L)
```

list2env*From A List, Build or Add To an Environment*

Description

From a *named* [list](#) `x`, create an [environment](#) containing all list components as objects, or “multi-assign” from `x` into a pre-existing environment.

Usage

```
list2env(x, envir = NULL, parent = parent.frame(),  
        hash = (length(x) > 100), size = max(29L, length(x)))
```

Arguments

<code>x</code>	a list , where <code>names(x)</code> must not contain empty ("") elements.
<code>envir</code>	an environment or <code>NULL</code> .
<code>parent</code>	(for the case <code>envir = NULL</code>): a parent frame aka enclosing environment, see new.env .
<code>hash</code>	(for the case <code>envir = NULL</code>): logical indicating if the created environment should use hashing, see new.env .
<code>size</code>	(in the case <code>envir = NULL, hash = TRUE</code>): hash size, see new.env .

Details

This will be very slow for large inputs unless hashing is used on the environment.

Environments must have uniquely named entries, but named lists need not: where the list has duplicate names it is the *last* element with the name that is used. Empty names throw an error.

Value

An [environment](#), either newly created (as by [new.env](#)) if the `envir` argument was `NULL`, otherwise the updated environment `envir`. Since environments are never duplicated, the argument `envir` is also changed.

Author(s)

Martin Maechler

See Also

[environment](#), [new.env](#), [as.environment](#); further, [assign](#).

The (semantical) “inverse”: [as.list.environment](#).

Examples

```
L <- list(a = 1, b = 2:4, p = pi, ff = gl(3, 4, labels = LETTERS[1:3]))
e <- list2env(L)
ls(e)
stopifnot(ls(e) == sort(names(L)),
          identical(L$b, e$b)) # "$" working for environments as for lists

## consistency, when we do the inverse:
ll <- as.list(e) # -> dispatching to the as.list.environment() method
rbind(names(L), names(ll)) # not in the same order, typically,
# but the same content:
stopifnot(identical(L [sort.list(names(L))],
                    ll[sort.list(names(ll))]))

## now add to e -- can be seen as a fast "multi-assign":
list2env(list(abc = LETTERS, note = "just an example",
             df = data.frame(x = rnorm(20), y = rbinom(20, 1, prob = 0.2))),
         envir = e)
utils::ls.str(e)
```

load

Reload Saved Datasets

Description

Reload datasets written with the function `save`.

Usage

```
load(file, envir = parent.frame(), verbose = FALSE)
```

Arguments

<code>file</code>	a (readable binary-mode) connection or a character string giving the name of the file to load (when tilde expansion is done).
<code>envir</code>	the environment where the data should be loaded.
<code>verbose</code>	should item names be printed during loading?

Details

`load` can load R objects saved in the current or any earlier format. It can read a compressed file (see [save](#)) directly from a file or from a suitable connection (including a call to [url](#)).

A not-open connection will be opened in mode `"rb"` and closed after use. Any connection other than a [gzfile](#) or [gzcon](#) connection will be wrapped in [gzcon](#) to allow compressed saves to be handled: note that this leaves the connection in an altered state (in particular, binary-only), and that it needs to be closed explicitly (it will not be garbage-collected).

Only R objects saved in the current format (used since R 1.4.0) can be read from a connection. If no input is available on a connection a warning will be given, but any input not in the current format will result in an error.

Loading from an earlier version will give a warning about the ‘magic number’: magic numbers 1971:1977 are from R < 0.99.0, and RD[ABX] 1 from R 0.99.0 to R 1.3.1. These are all obsolete, and you are strongly recommended to re-save such files in a current format.

The `verbose` argument is mainly intended for debugging. If it is `TRUE`, then as objects from the file are loaded, their names will be printed to the console. If `verbose` is set to an integer value greater than one, additional names corresponding to attributes and other parts of individual objects will also be printed. Larger values will print names to a greater depth.

Objects can be saved with references to namespaces, usually as part of the environment of a function or formula. Such objects can be loaded even if the namespace is not available: it is replaced by a reference to the global environment with a warning. The warning identifies the first object with such a reference (but there may be more than one).

Value

A character vector of the names of objects created, invisibly.

Warning

Saved R objects are binary files, even those saved with `ascii = TRUE`, so ensure that they are transferred without conversion of end of line markers. `load` tries to detect such a conversion and gives an informative error message.

`load(file)` replaces all existing objects with the same names in the current environment (typically your workspace, `.GlobalEnv`) and hence potentially overwrites important data. It is considerably safer to use `envir =` to load into a different environment, or to `attach(file)` which `load()` s into a new entry in the `search` path.

See Also

`save`, `download.file`; further `attach` as wrapper for `load()`.

For other interfaces to the underlying serialization format, see `unserialize` and `readRDS`.

Examples

```
## save all data
xx <- pi # to ensure there is some data
save(list = ls(all.names = TRUE), file = "all.rda")
rm(xx)

## restore the saved values to the current environment
local({
  load("all.rda")
  ls()
})

xx <- exp(1:3)
## restore the saved values to the user's workspace
load("all.rda") ## which is here *equivalent* to
## load("all.rda", .GlobalEnv)
## This however annihilates all objects in .GlobalEnv with the same names !
xx # no longer exp(1:3)
rm(xx)
attach("all.rda") # safer and will warn about masked objects w/ same name in .GlobalEnv
ls(pos = 2)
## also typically need to cleanup the search path:
detach("file:all.rda")
```

```
## clean up (the example):
unlink("all.rda")

## Not run:
con <- url("http://some.where.net/R/data/example.rda")
## print the value to see what objects were created.
print(load(con))
close(con) # url() always opens the connection

## End(Not run)
```

locales

*Query or Set Aspects of the Locale***Description**

Get details of or set aspects of the locale for the R process.

Usage

```
Sys.getlocale (category = "LC_ALL")
Sys.setlocale (category = "LC_ALL", locale = "")
.LC.categories
```

Arguments

category	character string. The following categories should always be supported: "LC_ALL", "LC_COLLATE", "LC_CTYPE", "LC_MONETARY", "LC_NUMERIC" and "LC_TIME". Some systems (not Windows) will also support "LC_MESSAGES", "LC_PAPER" and "LC_MEASUREMENT". These category names are available in <code>.LC.categories</code> ; even when not supported, <code>Sys.getlocale(.)</code> will return "", e.g., for the "LC_PAPER" example on Windows.
locale	character string. A valid locale name on the system in use. Normally "" (the default) will pick up the default locale for the system.

Details

The locale describes aspects of the internationalization of a program. Initially most aspects of the locale of R are set to "C" (which is the default for the C language and reflects North-American usage – also known as "POSIX"). R sets "LC_CTYPE" and "LC_COLLATE", which allow the use of a different character set and alphabetic comparisons in that character set (including the use of `sort`), "LC_MONETARY" (for use by `Sys.localeconv`) and "LC_TIME" may affect the behaviour of `as.POSIXlt` and `strptime` and functions which use them (but not `date`).

The first seven categories described here are those specified by POSIX. "LC_MESSAGES" will be "C" on systems that do not support message translation, and is not supported on Windows, where you *must* use the LANGUAGE environment variable for message translation, see below and the `Sys.setLanguage()` utility. Trying to use an unsupported category is an error for `Sys.setlocale`.

Note that setting category "LC_ALL" sets only categories "LC_COLLATE", "LC_CTYPE", "LC_MONETARY" and "LC_TIME".

Attempts to set an invalid locale are ignored. There may or may not be a warning, depending on the OS.

Attempts to change the character set (by `Sys.setlocale("LC_CTYPE", )`, if that implies a different character set) during a session may not work and are likely to lead to some confusion.

Note that the `LANGUAGE` environment variable has precedence over `"LC_MESSAGES"` in selecting the language for message translation on most R platforms.

On platforms where ICU is used for collation the locale used for collation can be reset by `icuSetCollate`. Except on Windows, the initial setting is taken from the `"LC_COLLATE"` category, and it is reset when this is changed by a call to `Sys.setlocale`.

Value

A character string of length one describing the locale in use (after setting for `Sys.setlocale`), or an empty character string if the current locale settings are invalid or `NULL` if locale information is unavailable.

For `category = "LC_ALL"` the details of the string are system-specific: it might be a single locale name or a set of locale names separated by `"/"` (macOS) or `";"` (Windows, Linux). For portability, it is best to query categories individually: it is not necessarily the case that the result of `foo <- Sys.getlocale()` can be used in `Sys.setlocale("LC_ALL", locale = foo)`.

Available locales

On most Unix-alikes the POSIX shell command `locale -a` will list the ‘available public’ locales. What that means is platform-dependent. On recent Linuxen this may mean ‘available to be installed’ as on some RPM-based systems the locale data is in separate RPMs. On Debian/Ubuntu the set of available locales is managed by OS-specific facilities such as `locale-gen` and `locale -a` lists those currently enabled.

For Windows, Microsoft moves its documentation frequently so a Web search is the best way to find current information. From R 4.2, UCRT locale names should be used. The character set should match the system/ANSI codepage (`l10n_info()$codepage` be the same as `l10n_info()$system.codepage`). Setting it to any other value results in a warning and may cause encoding problems. As from R 4.2 on recent Windows the system codepage is 65001 and one should always use locale names ending with `".UTF-8"` (except for `"C"` and `""`), otherwise Windows may add a different character set.

Warning

Setting `"LC_NUMERIC"` to any value other than `"C"` may cause R to function anomalously, so gives a warning. Input conversions in R itself are unaffected, but the reading and writing of ASCII `save` files will be, as may packages which do their own input/output.

Setting it temporarily on a Unix-alike to produce graphical or text output may work well enough, but `options(OutDec)` is often preferable.

Almost all the output routines used by R itself under Windows ignore the setting of `"LC_NUMERIC"` since they make use of the Trio library which is not internationalized.

Note

Changing the values of locale categories whilst R is running ought to be noticed by the OS services, and usually is but exceptions have been seen (usually in collation services).

Do not use the value of `Sys.getlocale("LC_CTYPE")` to attempt to find the character set – for example UTF-8 locales can have suffix `‘.UTF-8’` or `‘.utf8’` (more common on Linux than `‘UTF-8’`) or none (as on macOS) and Latin-9 locales can have suffix `‘ISO8859-15’`, `‘iso885915’`, `‘iso885915@euro’` or `‘ISO8859-15@euro’`. Use [l10n_info](#) instead.

See Also

[strptime](#) for uses of category = "LC_TIME". [Sys.localeconv](#) for details of numerical and monetary representations.

[l10n_info](#) gives some summary facts about the locale and its encoding (including if it is UTF-8).

Section **“Locales”** in *R Installation and Administration* for background on locales and how to find out locale names on your system.

[Sys.setLanguage](#)

Examples

```
Sys.getlocale()

## Date-time related :
Sys.getlocale("LC_TIME") -> olcT
then <- as.POSIXlt("2001-01-01 01:01:01", tz = "UTC")
## Not run:
c(m = months(then), wd = weekdays(then)) # locale specific
Sys.setlocale("LC_TIME", "de")           # Solaris: details are OS-dependent
Sys.setlocale("LC_TIME", "de_DE")        # Many Unix-alikes
Sys.setlocale("LC_TIME", "de_DE.UTF-8")  # Linux, macOS, other Unix-alikes
Sys.setlocale("LC_TIME", "de_DE.utf8")   # some Linux versions
Sys.setlocale("LC_TIME", "German.UTF-8") # Windows
Sys.getlocale("LC_TIME") # the last one successfully set above
c(m = months(then), wd = weekdays(then)) # in C_TIME locale 'cT' ; typically German

## End(Not run)
Sys.setlocale("LC_TIME", "C")
c(m = months(then), wd = weekdays(then)) # "standard" (still platform specific ?)
Sys.setlocale("LC_TIME", olcT)           # reset to previous

## Other locales
Sys.getlocale("LC_PAPER")                # may or may not be set
.LC.categories # of length 9 on all platforms

## Not run: Sys.setlocale("LC_COLLATE", "C") # turn off locale-specific sorting,
                                             # usually (but not on all platforms)
Sys.setenv("LANGUAGE" = "es") # set the language for error/warning messages

## End(Not run)
## some nice formatting; should work on most platforms,
## macOS does not name the entries.
sep <- switch(Sys.info()[["sysname"]],
              "Darwin" =, "SunOS" = "/",
              "Linux" =, "Windows" = ";")
## ' named vector from a "full" Sys.getlocale() :
asNvec <- function(loc) {
  sl <- strsplit(strsplit(loc, sep)[[1L]], "=")
  if(all(lengths(sl) == 2L))
    setNames(sapply(sl, `[`, 2L), sapply(sl, `[`, 1L))
}
```

```

    else
      setNames(as.character(sl), .LC.categories[1+seq_along(sl)])
  }
  print.Dlist(lloc <- asNvec(Sys.getlocale()))
  ## R-supported ones (but LC_ALL):
  lloc[.LC.categories[-1]]

```

log

*Logarithms and Exponentials***Description**

`log` computes logarithms, by default natural logarithms, `log10` computes common (i.e., base 10) logarithms, and `log2` computes binary (i.e., base 2) logarithms. The general form `log(x, base)` computes logarithms with base `base`.

`log1p(x)` computes $\log(1+x)$ accurately also for $|x| \ll 1$.

`exp` computes the exponential function.

`expm1(x)` computes $\exp(x) - 1$ accurately also for $|x| \ll 1$.

Usage

```

log(x, base = exp(1))
logb(x, base = exp(1))
log10(x)
log2(x)

log1p(x)

exp(x)
expm1(x)

```

Arguments

<code>x</code>	a numeric or complex vector.
<code>base</code>	a positive or complex number: the base with respect to which logarithms are computed. Defaults to $e = \exp(1)$.

Details

All except `logb` are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

`log10` and `log2` are only convenience wrappers, but logs to bases 10 and 2 (whether computed *via* `log` or the wrappers) will be computed more efficiently and accurately where supported by the OS. Methods can be set for them individually (and otherwise methods for `log` will be used).

`logb` is a wrapper for `log` for compatibility with S. If (S3 or S4) methods are set for `log` they will be dispatched. Do not set S4 methods on `logb` itself.

All except `log` are [primitive](#) functions.

Value

A vector of the same length as `x` containing the transformed values. `log(0)` gives `-Inf`, and `log(x)` for negative values of `x` is `NaN`. `exp(-Inf)` is 0.

For complex inputs to the log functions, the value is a complex number with imaginary part in the range $[-\pi, \pi]$: which end of the range is used might be platform-specific.

S4 methods

`exp`, `expm1`, `log`, `log10`, `log2` and `log1p` are S4 generic and are members of the `Math` group generic.

Note that this means that the S4 generic for `log` has a signature with only one argument, `x`, but that `base` can be passed to methods (but will not be used for method selection). On the other hand, if you only set a method for the `Math` group generic then `base` argument of `log` will be ignored for your class.

Source

`log1p` and `expm1` may be taken from the operating system, but if not available there then they are based on the Fortran subroutine `dlnrel` by W. Fullerton of Los Alamos Scientific Laboratory (see <https://netlib.org/slatec/fnlib/dlnrel.f>) and (for small `x`) a single Newton step for the solution of `log1p(y) = x` respectively.

Chambers JM (1998). *Programming with Data*. Springer, New York. ISBN 978-0-387-98503-9. (for `logb`.)

See Also

`Trig`, `sqrt`, `Arithmetic`.

Examples

```
log(exp(3))
log10(1e7) # = 7

x <- 10^-(1+2*1:9)
cbind(deparse.level=2, # to get nice column names
      x, log(1+x), log1p(x), exp(x)-1, expm1(x))
```

Description

These operators act on raw, logical and number-like vectors.

Usage

```
! x
x & y
x && y
x | y
x || y
xor(x, y)

isTRUE(x)
isFALSE(x)
```

Arguments

`x, y` [raw](#), [logical](#) or ‘number-like’ vectors (i.e., of types [double](#) (class [numeric](#)), [integer](#) and [complex](#)), or objects for which methods have been written.

Details

`!` indicates logical negation (NOT).

`&` and `&&` indicate logical AND and `|` and `||` indicate logical OR. The shorter forms performs elementwise comparisons in much the same way as arithmetic operators. The longer forms evaluates left to right, proceeding only until the result is determined. The longer form is appropriate for programming control-flow and typically preferred in [if](#) clauses.

Using vectors of more than one element in `&&` or `||` will give an error.

`xor` indicates elementwise exclusive OR.

`isTRUE(x)` is the same as `{ is.logical(x) && length(x) == 1 && !is.na(x) && x }`; `isFALSE()` is defined analogously. Consequently, `if(isTRUE(cond))` may be preferable to `if(cond)` because of [NAs](#).

In earlier R versions, `isTRUE <- function(x) identical(x, TRUE)`, had the drawback to be false e.g., for `x <- c(val = TRUE)`.

Numeric and complex vectors will be coerced to logical values, with zero being false and all non-zero values being true. Raw vectors are handled without any coercion for `!`, `&`, `|` and `xor`, with these operators being applied bitwise (so `!` is the 1s-complement).

The operators `!`, `&` and `|` are generic functions: methods can be written for them individually or via the [Ops](#) (or S4 [Logic](#), see below) group generic function. (See [Ops](#) for how dispatch is computed.)

[NA](#) is a valid logical object. Where a component of `x` or `y` is `NA`, the result will be `NA` if the outcome is ambiguous. In other words `NA & TRUE` evaluates to `NA`, but `NA & FALSE` evaluates to `FALSE`. See the examples below.

See [Syntax](#) for the precedence of these operators: unlike many other languages (including S) the AND and OR operators do not have the same precedence (the AND operators have higher precedence than the OR operators).

Value

For `!`, a logical or raw vector (for raw `x`) of the same length as `x`: names, dims and dimnames are copied from `x`, and all other attributes (including class) if no coercion is done.

For `|`, `&` and `xor` a logical or raw vector. If involving a zero-length vector the result has length zero. Otherwise, the elements of shorter vectors are recycled as necessary (with a [warning](#) when

they are recycled only *fractionally*). The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and `tsp` attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

For `||`, `&&` and `isTRUE`, a length-one logical vector.

S4 methods

`!`, `&` and `|` are S4 generics, the latter two part of the `Logic` group generic (and hence methods need argument names `e1`, `e2`).

Note

The elementwise operators are sometimes called as functions as e.g. ``&`(x, y)`: see the description of how argument-matching is done in [Ops](#).

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[TRUE](#) or [logical](#).

[any](#) and [all](#) for OR and AND on many scalar arguments.

[Syntax](#) for operator precedence.

`L %||% R` which takes `L` if it is not `NULL`, and `R` otherwise.

[bitwAnd](#) for bitwise versions for integer vectors.

Examples

```
y <- 1 + (x <- stats::rpois(50, lambda = 1.5) / 4 - 1)
x[(x > 0) & (x < 1)]      # all x values between 0 and 1
if (any(x == 0) || any(y == 0)) "zero encountered"

## construct truth tables :

x <- c(NA, FALSE, TRUE)
names(x) <- as.character(x)
outer(x, x, `&`) ## AND table
outer(x, x, `|`) ## OR table
```

logical

Logical Vectors

Description

Create or test for objects of type "logical", and the basic logical constants.

Usage

```
TRUE
FALSE
T; F

logical(length = 0)
as.logical(x, ...)
is.logical(x)
```

Arguments

length	a non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

TRUE and FALSE are [reserved](#) words denoting logical constants in the R language, whereas T and F are global variables whose initial values set to these. All four are `logical(1)` vectors.

`as.logical` is a generic function. Methods should return an object of type "logical".

Logical vectors are coerced to integer vectors in contexts where a numerical value is required, with TRUE being mapped to 1L, FALSE to 0L and NA to `NA_integer_`.

Value

`logical` creates a logical vector of the specified length. Each element of the vector is equal to FALSE.

`as.logical` attempts to coerce its argument to be of logical type. In numeric and complex vectors, zeros are FALSE and non-zero values are TRUE. For [factors](#), this uses the [levels](#) (labels). Like [as.vector](#) it strips attributes including names. Character strings `c("T", "TRUE", "True", "true")` are regarded as true, `c("F", "FALSE", "False", "false")` as false, and all others as NA.

`is.logical` returns TRUE or FALSE depending on whether its argument is of logical type or not.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[NA](#), the other logical constant. Logical operators are documented in [Logic](#).

Examples

```
## non-zero values are TRUE
as.logical(c(pi,0))
if (length(letters)) cat("26 is TRUE\n")

## logical interpretation of particular strings
charvec <- c("FALSE", "F", "False", "false", "fAlse", "0",
             "TRUE", "T", "True", "true", "tRue", "1")
as.logical(charvec)

## factors are converted via their levels, so string conversion is used
as.logical(factor(charvec))
as.logical(factor(c(0,1))) # "0" and "1" give NA
```

LongVectors

Long Vectors

Description

Vectors of 2^{31} or more elements were added in R 3.0.0.

Details

Prior to R 3.0.0, all vectors in R were restricted to at most $2^{31} - 1$ elements and could be indexed by integer vectors.

Currently all [atomic](#) (raw, logical, integer, numeric, complex, character) vectors, [lists](#) and [expressions](#) can be much longer on 64-bit platforms: such vectors are referred to as ‘long vectors’ and have a slightly different internal structure. In theory they can contain up to 2^{52} elements, but address space limits of current CPUs and OSes will be much smaller. Such objects will have a [length](#) that is expressed as a double, and can be indexed by double vectors.

Arrays (including matrices) can be based on long vectors provided each of their dimensions is at most $2^{31} - 1$; thus there are no 1-dimensional long arrays.

R code typically only needs minor changes to work with long vectors, maybe only checking that `as.integer` is not used unnecessarily for e.g. lengths. However, compiled code typically needs quite extensive changes. Note that the `.C` and `.Fortran` interfaces do not accept long vectors, so `.Call` (or similar) has to be used.

Because of the storage requirements (a minimum of 64 bytes per character string), character vectors are only going to be usable if they have a small number of distinct elements, and even then factors will be more efficient (4 bytes per element rather than 8). So it is expected that most of the usage of long vectors will be integer vectors (including factors) and numeric vectors.

Matrix algebra

It is now possible to use $m \times n$ matrices with more than 2 billion elements. Whether matrix algebra (including `%*%`, `crossprod`, `svd`, `qr`, `solve` and `eigen`) will actually work is somewhat implementation dependent, including the Fortran compiler used and if an external BLAS or LAPACK is used.

An efficient parallel BLAS implementation will often be important to obtain usable performance. For example on one particular platform `chol` on a 47,000 square matrix took about 5 hours with the internal BLAS, 21 minutes using an optimized BLAS on one core, and 2 minutes using an optimized BLAS on 16 cores.

`lower.tri`

Lower and Upper Triangular Part of a Matrix

Description

Returns a matrix of logicals the same size of a given matrix with entries `TRUE` in the lower or upper triangle.

Usage

```
lower.tri(x, diag = FALSE)
upper.tri(x, diag = FALSE)
```

Arguments

<code>x</code>	a matrix or other R object with <code>length(dim(x)) == 2</code> . For back compatibility reasons, when the above is not fulfilled, <code>as.matrix(x)</code> is called first.
<code>diag</code>	logical. Should the diagonal be included?

See Also

`diag`, `matrix`; further `row` and `col` on which `lower.tri()` and `upper.tri()` are built.

Examples

```
(m2 <- matrix(1:20, 4, 5))
lower.tri(m2)
m2[lower.tri(m2)] <- NA
m2
```

`ls`

List Objects

Description

`ls` and `objects` return a vector of character strings giving the names of the objects in the specified environment. When invoked with no argument at the top level prompt, `ls` shows what data sets and functions a user has defined. When invoked with no argument inside a function, `ls` returns the names of the function's local variables: this is useful in conjunction with `browser`.

Usage

```
ls(name, pos = -1L, envir = as.environment(pos),
   all.names = FALSE, pattern, sorted = TRUE)
objects(name, pos = -1L, envir = as.environment(pos),
        all.names = FALSE, pattern, sorted = TRUE)
```

Arguments

<code>name</code>	which environment to use in listing the available objects. Defaults to the <i>current</i> environment. Although called <code>name</code> for back compatibility, in fact this argument can specify the environment in any form; see the ‘Details’ section.
<code>pos</code>	an alternative argument to <code>name</code> for specifying the environment as a position in the search list. Mostly there for back compatibility.
<code>envir</code>	an alternative argument to <code>name</code> for specifying the environment. Mostly there for back compatibility.
<code>all.names</code>	a logical value. If <code>TRUE</code> , all object names are returned. If <code>FALSE</code> , names which begin with a ‘.’ are omitted.
<code>pattern</code>	an optional regular expression . Only names matching <code>pattern</code> are returned. glob2rx can be used to convert wildcard patterns to regular expressions.
<code>sorted</code>	logical indicating if the resulting character should be sorted alphabetically. Note that this is part of <code>ls()</code> may take most of the time.

Details

The `name` argument can specify the environment from which object names are taken in one of several forms: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an explicit [environment](#) (including using `sys.frame` to access the currently active function calls). By default, the environment of the call to `ls` or `objects` is used. The `pos` and `envir` arguments are an alternative way to specify an environment, but are primarily there for back compatibility.

Note that the *order* of strings for `sorted = TRUE` is locale dependent, see [Sys.getlocale](#). If `sorted = FALSE` the order is arbitrary, depending if the environment is hashed, the order of insertion of objects, ...

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[glob2rx](#) for converting wildcard patterns to regular expressions.

[ls.str](#) for a long listing based on [str](#). [apropos](#) (or [find](#)) for finding objects in the whole search path; [grep](#) for more details on ‘regular expressions’; [class](#), [methods](#), etc., for object-oriented programming.

Examples

```
.Ob <- 1
ls(pattern = "O")
ls(pattern= "O", all.names = TRUE)      # also shows ".[foo]"

# shows an empty list because inside myfunc no variables are defined
myfunc <- function() {ls()}
myfunc()

# define a local variable inside myfunc
myfunc <- function() {y <- 1; ls()}
myfunc()          # shows "y"
```

`make.names`*Make Syntactically Valid Names*

Description

Make syntactically valid names out of character vectors.

Usage

```
make.names(names, unique = FALSE, allow_ = TRUE)
```

Arguments

<code>names</code>	character vector to be coerced to syntactically valid names. This is coerced to character if necessary.
<code>unique</code>	logical; if <code>TRUE</code> , the resulting elements are unique. This may be desired for, e.g., column names.
<code>allow_</code>	logical. For compatibility with R prior to 1.9.0.

Details

A syntactically valid name consists of letters, numbers and the dot or underline characters and starts with a letter or the dot not followed by a number. Names such as `".2way"` are not valid, and neither are the [reserved](#) words.

The definition of a *letter* depends on the current locale, but only ASCII digits are considered to be digits.

The character `"X"` is prepended if necessary. All invalid characters are translated to `". "`. A missing value is translated to `"NA"`. Names which match R keywords have a dot appended to them. Duplicated values are altered by [make.unique](#).

Value

A character vector of same length as `names` with each changed to a syntactically valid name, in the current locale's encoding.

Warning

Some OSes, notably FreeBSD, report extremely incorrect information about which characters are alphabetic in some locales (typically, all multi-byte locales including UTF-8 locales). However, R provides substitutes on Windows, macOS and AIX.

Note

Prior to R version 1.9.0, underscores were not valid in variable names, and code that relies on them being converted to dots will no longer work. Use `allow_ = FALSE` for back-compatibility.

`allow_ = FALSE` is also useful when creating names for export to applications which do not allow underline in names (such as some DBMSes).

See Also

[make.unique](#), [names](#), [character](#), [data.frame](#).

Examples

```

make.names(c("a and b", "a-and-b"), unique = TRUE)
# "a.and.b" "a.and.b.1"
make.names(c("a and b", "a_and_b"), unique = TRUE)
# "a.and.b" "a_and_b"
make.names(c("a and b", "a_and_b"), unique = TRUE, allow_ = FALSE)
# "a.and.b" "a.and.b.1"
make.names(c("", "X"), unique = TRUE)
# "X.1" "X" currently; R up to 3.0.2 gave "X" "X.1"

state.name[make.names(state.name) != state.name] # those 10 with a space

```

make.unique	<i>Make Character Strings Unique</i>
-------------	--------------------------------------

Description

Makes the elements of a character vector unique by appending sequence numbers to duplicates.

Usage

```
make.unique(names, sep = ".")
```

Arguments

names	a character vector.
sep	a character string used to separate a duplicate name from its sequence number.

Details

The algorithm used by `make.unique` has the property that `make.unique(c(A, B)) == make.unique(c(make.unique(A), B))`.

In other words, you can append one string at a time to a vector, making it unique each time, and get the same result as applying `make.unique` to all of the strings at once.

If character vector `A` is already unique, then `make.unique(c(A, B))` preserves `A`.

Value

A character vector of same length as `names` with duplicates changed, in the current locale's encoding.

Author(s)

Thomas P. Minka

See Also

[make.names](#)

Examples

```
make.unique(c("a", "a", "a"))
make.unique(c(make.unique(c("a", "a")), "a"))

make.unique(c("a", "a", "a.2", "a"))
make.unique(c(make.unique(c("a", "a")), "a.2", "a"))

## Now show a bit where this is used :
trace(make.unique)
## Applied in data.frame() constructions:
(d1 <- data.frame(x = 1, x = 2, x = 3)) # direct
d2 <- data.frame(data.frame(x = 1, x = 2), x = 3) # pairwise
stopifnot(identical(d1, d2),
           colnames(d1) == c("x", "x.1", "x.2"))
untrace(make.unique)
```

mapply

Apply a Function to Multiple List or Vector Arguments

Description

`mapply` is a multivariate version of `sapply`. `mapply` applies `FUN` to the first elements of each `...` argument, the second elements, the third elements, and so on. Arguments are recycled if necessary.

`.mapply()` is a bare-bones version of `mapply()`, e.g., to be used in other functions.

Usage

```
mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE,
       USE.NAMES = TRUE)
.mapply(FUN, dots, MoreArgs)
```

Arguments

<code>FUN</code>	function to apply, found via <code>match.fun</code> .
<code>...</code>	arguments to vectorize over, will be recycled to common length (zero if one of them is). See also ‘Details’.
<code>dots</code>	<code>list</code> or <code>pairlist</code> of arguments to vectorize over, see <code>...</code> above.
<code>MoreArgs</code>	a list of other arguments to <code>FUN</code> .
<code>SIMPLIFY</code>	logical or character string; attempt to reduce the result to a vector, matrix or higher dimensional array; see the <code>simplify</code> argument of <code>sapply</code> .
<code>USE.NAMES</code>	logical; use the names of the first <code>...</code> argument, or if that is an unnamed character vector, use that vector as the names.

Details

`mapply` calls `FUN` for the values of `...` (re-cycled to the length of the longest, unless any have length zero where recycling to zero length will return `list()`), followed by the arguments given in `MoreArgs`. The arguments in the call will be named if `...` or `MoreArgs` are named.

For the arguments in `...` (or components in `dots`) class specific subsetting (such as `[]`) and `length` methods will be used where applicable.

Value

A [list](#), or for SIMPLIFY = TRUE, a vector, array or list.

See Also

[sapply](#), after which `mapply()` is modelled.
[outer](#), which applies a vectorized function to all combinations of two arguments.

Examples

```
mapply(rep, 1:4, 4:1)

mapply(rep, times = 1:4, x = 4:1)

mapply(rep, times = 1:4, MoreArgs = list(x = 42))

mapply(function(x, y) seq_len(x) + y,
       c(a = 1, b = 2, c = 3), # names from first
       c(A = 10, B = 0, C = -10))

word <- function(C, k) paste(rep.int(C, k), collapse = "")
## names from the first, too:
utils::str(L <- mapply(word, LETTERS[1:6], 6:1, SIMPLIFY = FALSE))

mapply(word, "A", integer()) # gave Error, now list()
```

marginSums	<i>Compute Table Margins</i>
------------	------------------------------

Description

For a contingency table in array form, compute the sum of table entries for a given margin or set of margins.

Usage

```
marginSums(x, margin = NULL)
margin.table(x, margin = NULL)
```

Arguments

- `x` an array, usually a [table](#).
- `margin` a vector giving the margins to compute sums for. E.g., for a matrix 1 indicates rows, 2 indicates columns, `c(1, 2)` indicates rows and columns. When `x` has named [dimnames](#), it can be a character vector selecting dimension names.

Value

The relevant marginal table, or just the sum of all entries if `margin` has length zero. The class of `x` is copied to the output table if `margin` is non-NULL.

Note

`margin.table` is an earlier name, retained for back-compatibility.

Author(s)

Peter Dalgaard

See Also

[rowSums](#) and [colSums](#) for similar functionality.

[proportions](#) and [addmargins](#).

Examples

```
m <- matrix(1:4, 2)
marginSums(m, 1)  # = rowSums(m)
marginSums(m, 2)  # = colSums(m)

DF <- as.data.frame(UCBAdmissions)
tbl <- xtabs(Freq ~ Gender + Admit, DF)
tbl
marginSums(tbl, "Gender")  # a 1-dim "table"
rowSums(tbl)               # a numeric vector
```

mat.or.vec

Create a Matrix or a Vector

Description

`mat.or.vec` creates an `nr` by `nc` zero matrix if `nc` is greater than 1, and a zero vector of length `nr` if `nc` equals 1.

Usage

```
mat.or.vec(nr, nc)
```

Arguments

`nr, nc` numbers of rows and columns.

Examples

```
mat.or.vec(3, 1)
mat.or.vec(3, 2)
```

match

*Value Matching***Description**

`match` returns a vector of the positions of (first) matches of its first argument in its second.

`%in%` and `%notin%` are more intuitive interfaces as binary operators, returning a logical vector indicating if there is a match or not for its left operand.

Usage

```
match(x, table, nomatch = NA_integer_, incomparables = NULL)
```

```
x %in% table
```

```
x %notin% table
```

Arguments

<code>x</code>	vector or <code>NULL</code> : the values to be matched. Long vectors are supported.
<code>table</code>	vector or <code>NULL</code> : the values to be matched against. Long vectors are not supported.
<code>nomatch</code>	the value to be returned in the case when no match is found. Note that it is coerced to <code>integer</code> .
<code>incomparables</code>	a vector of values that cannot be matched. Any value in <code>x</code> matching a value in this vector is assigned the <code>nomatch</code> value. For historical reasons, <code>FALSE</code> is equivalent to <code>NULL</code> .

Details

`%in%` is currently defined as

```
`%in%` <- function(x, table) match(x, table, nomatch = 0L) > 0L
```

`%notin%` could succinctly be defined as [Negate](#)(``%in%``), but for symmetry and efficiency is

```
`%notin%` <- function(x, table) match(x, table, nomatch = 0L) == 0L
```

Factors, raw vectors and lists are converted to character vectors, internally classed objects are transformed via [mtfrm](#), and then `x` and `table` are coerced to a common type (the later of the two types in R's ordering, logical < integer < numeric < complex < character) before matching. If `incomparables` has positive length it is coerced to the common type.

One exception to the above happens when `match()` ing [Date](#) objects and [characters](#). There, the character argument is coerced to "Date" (via [as.Date.character\(\)](#)) before the above `mtfrm()` is applied.

Matching for lists is potentially very slow and best avoided except in simple cases.

Exactly what matches what is to some extent a matter of definition. For all types, `NA` matches `NA` and no other value. For real and complex values, `NaN` values are regarded as matching any other `NaN` value, but not matching `NA`, where for complex `x`, real and imaginary parts must match both (unless containing at least one `NA`), see the examples.

Character strings will be compared as byte sequences if any input is marked as "bytes", and otherwise are regarded as equal if they are in different encodings but would agree when translated to UTF-8 (see [Encoding](#)).

That `%in%` and `%notin%` never return NA makes them particularly useful in `if` conditions.

Value

A vector of the same length as `x`.

`match`: An integer vector giving the position in `table` of the first match if there is a match, otherwise `nomatch`.

If `x[i]` is found to equal `table[j]` then the value returned in the `i`-th position of the return value is `j`, for the smallest possible `j`. If no match is found, the value is `nomatch`.

`%in%`: A logical vector, indicating if a match was located for each element of `x`: thus the values are TRUE or FALSE and never NA.

`%notin%`: A logical vector, simply the negation of the corresponding `%in%` call.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`pmatch` and `charmatch` for (partial) string matching, `match.arg`, etc for function argument matching. `findInterval` similarly returns a vector of positions, but finds numbers within intervals, rather than exact matches.

`is.element` for an S-compatible equivalent of `%in%`.

`unique` (and `duplicated`) are using the same definitions of “match” or “equality” as `match()`, and these are less strict than `==`, e.g., for NA and NaN in numeric or complex vectors, or for strings with different encodings, see also above.

Examples

```
## The intersection of two sets can be defined via match():
## Simple version:
## intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect # the R function in base is slightly more careful
intersect(1:10, 7:20)

1:10 %in% c(1,3,5,9)
sstr <- c("c", "ab", "B", "bba", "c", NA, "@", "bla", "a", "Ba", "%")
sstr[sstr %in% c(letters, LETTERS)]

"%w/o%" <- function(x, y) x[x %notin% y] #-- x without y
(1:10) %w/o% c(3,7,12)
## Note that setdiff() is very similar and typically makes more sense:
      c(1:6,7:2) %w/o% c(3,7,12) # -> keeps duplicates
setdiff(c(1:6,7:2),      c(3,7,12)) # -> unique values
## Illuminating example about NA matching in complex values
r <- c(1, NA, NaN)
zN <- c(complex(real = NA , imaginary = r ),
        complex(real = r , imaginary = NA ),
```

```

      complex(real = r , imaginary = NaN),
      complex(real = NaN, imaginary = r ))
zM <- cbind(Re=Re(zN), Im=Im(zN), match = match(zN, zN))
rownames(zM) <- format(zN)
zM ##--> many "NA" matches (= 1) and four non-NAs (3 different ones: 7,9,10)

length(zN) # 12
unique(zN) # the "NA" and the 3 different NaN values
stopifnot(identical(unique(zN), zN[c(1, 7,9,10)]))
stopifnot(is.na(zN)) # all are regarded as missing

## very strict equality would have 4 duplicates (of 12):
symnum(outer(zN, zN, Vectorize(identical,c("x","y")),
      FALSE,FALSE,FALSE,FALSE))
## removing "(very strictly) duplicates",
i <- c(5,8,11,12) # we get 8 pairwise non-identicals :
Ixy <- outer(zN[-i], zN[-i], Vectorize(identical,c("x","y")),
      FALSE,FALSE,FALSE,FALSE)
stopifnot(identical(Ixy, diag(8) == 1))

```

match.arg

Argument Verification Using Partial Matching

Description

`match.arg` matches a character `arg` against a table of candidate values as specified by `choices`.

Usage

```
match.arg(arg, choices, several.ok = FALSE)
```

Arguments

<code>arg</code>	a character vector (of length one unless <code>several.ok</code> is TRUE) or NULL which means to take <code>choices[1]</code> .
<code>choices</code>	a character vector of candidate values, often missing, see ‘Details’.
<code>several.ok</code>	either a logical specifying if <code>arg</code> should be allowed to have more than one element or a string, starting with "all" meaning that <code>arg</code> may have more than one element <i>all</i> of which must match <code>choices</code> .

Details

In the one-argument form `match.arg(arg)`, the choices are obtained from a default setting for the formal argument `arg` of the function from which `match.arg` was called. (Since default argument matching will set `arg` to `choices`, this is allowed as an exception to the ‘length one unless `several.ok` is TRUE’ rule, and returns the first element.)

Matching is done using [pmatch](#), so `arg` may be abbreviated and the empty string ("") never matches, not even itself, see [pmatch](#).

Value

The unabbreviated version of the exact or unique partial match if there is one; otherwise, an error is signalled if `several.ok` is false, as per default. When `several.ok` is true and (at least) one element of `arg` has a match, all unabbreviated versions of matches are returned.

Warning

The error messages given are liable to change and did so in R 4.2.0. Do not test them in packages.

See Also

[pmatch](#), [match.fun](#), [match.call](#).

Examples

```
require(stats)
## Extends the example for 'switch'
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg(type)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
center(x, "t")      # Works
center(x, "med")     # Works
try(center(x, "m"))  # Error
stopifnot(identical(center(x),      center(x, "mean")),
           identical(center(x, NULL), center(x, "mean")))

## Allowing more than one 'arg' and hence more than one match:
match.arg(c("gauss", "rect", "ep"),
  c("gaussian", "epanechnikov", "rectangular", "triangular"),
  several.ok = TRUE)
match.arg(c("a", ""), c("", NA, "bb", "abc"), several.ok=TRUE) # |-->  "abc"

## New (2025-'26) option several.ok = "all" (or "all.match", "all_must_match", "all*" ...)
## --> Error if *some* of the several do not match:
abcd <- c("a", "b", "c", "d")
try(match.arg(abcd, c("b", "c"), several.ok = FALSE)) # Error: ... 'arg' must be of length
  match.arg(abcd, c("b", "c"), several.ok = TRUE) # "b" "c"
try(match.arg(abcd, c("b", "c"), several.ok = "all")) # Error: ... should be one of "b",
## i.e. _all_ of 'arg' must match the choices:
(m1 <- match.arg(abcd, letters, several.ok = TRUE      )) # "a" "b" "c" "d"
(m2 <- match.arg(abcd, letters, several.ok = "all.match")) #      ditto
stopifnot(identical(m1, abcd), identical(m1, m2),
           identical(abcd, match.arg(abcd, abcd, several.ok = TRUE)),
           identical(abcd, match.arg(abcd, abcd, several.ok = "all_must_match")))
```

match.call

Argument Matching

Description

`match.call` returns a call in which all of the specified arguments are specified by their full names.

Usage

```
match.call(definition = sys.function(sys.parent()),
           call = sys.call(sys.parent()),
           expand.dots = TRUE,
           envir = parent.frame(2L))
```

Arguments

<code>definition</code>	a function, by default the function from which <code>match.call</code> is called. See details.
<code>call</code>	an unevaluated call to the function specified by <code>definition</code> , as generated by call .
<code>expand.dots</code>	logical. Should arguments matching <code>...</code> in the call be included or left as a <code>...</code> argument?
<code>envir</code>	an environment, from which the <code>...</code> in <code>call</code> are retrieved, if any.

Details

‘function’ on this help page means an interpreted function (also known as a ‘closure’): `match.call` does not support primitive functions (where argument matching is normally positional).

`match.call` is most commonly used in two circumstances:

- To record the call for later re-use: for example most model-fitting functions record the call as element `call` of the list they return. Here the default `expand.dots = TRUE` is appropriate.
- To pass most of the call to another function, often `model.frame`. Here the common idiom is that `expand.dots = FALSE` is used, and the `...` element of the matched call is removed. An alternative is to explicitly select the arguments to be passed on, as is done in `lm`.

Calling `match.call` outside a function without specifying `definition` is an error.

Value

An object of class `call`.

References

Chambers JM (1998). *Programming with Data*. Springer, New York. ISBN 978-0-387-98503-9.

See Also

[sys.call\(\)](#) is similar, but does *not* expand the argument names; [call](#), [pmatch](#), [match.arg](#), [match.fun](#).

Examples

```
match.call(get, call("get", "abc", i = FALSE, p = 3))
## -> get(x = "abc", pos = 3, inherits = FALSE)
fun <- function(x, lower = 0, upper = 1) {
  structure((x - lower) / (upper - lower), CALL = match.call())
}
fun(4 * atan(1), u = pi)
```

`match.fun`*Extract a Function Specified by Name*

Description

When called inside functions that take a function as argument, extract the desired function object while avoiding undesired matching to objects of other types.

Usage

```
match.fun(FUN, descend = TRUE)
```

Arguments

<code>FUN</code>	item to match as function: a function, symbol or character string. See ‘Details’.
<code>descend</code>	logical; control whether to search past non-function objects.

Details

`match.fun` is not intended to be used at the top level since it will perform matching in the *parent* of the caller.

If `FUN` is a function, it is returned. If it is a symbol (for example, enclosed in backquotes) or a character vector of length one, it will be looked up using `get` in the environment of the parent of the caller. If it is of any other mode, it is attempted first to get the argument to the caller as a symbol (using `substitute` twice), and if that fails, an error is declared.

If `descend = TRUE`, `match.fun` will look past non-function objects with the given name; otherwise if `FUN` points to a non-function object then an error is generated.

This is used in base functions such as [apply](#), [lapply](#), [outer](#), and [sweep](#).

Value

A function matching `FUN` or an error is generated.

Bugs

The `descend` argument is a bit of misnomer and probably not actually needed by anything. It may go away in the future.

It is impossible to fully foolproof this. If one `attaches` a list or data frame containing a length-one character vector with the same name as a function, it may be used (although namespaces will help).

Author(s)

Peter Dalgaard and Robert Gentleman, based on an earlier version by Jonathan Rougier.

See Also

[match.arg](#), [get](#)

Examples

```
# Same as get("*"):
match.fun("*")
# Overwrite outer with a vector
outer <- 1:5
try(match.fun(outer, descend = FALSE)) #-> Error: not a function
match.fun(outer) # finds it anyway
is.function(match.fun("outer")) # as well
```

MathFun

Miscellaneous Mathematical Functions

Description

`abs(x)` computes the absolute value of `x`, `sqrt(x)` computes the (principal) square root of `x`, $\sqrt{x}$.

The naming follows the standard for computer languages such as C or Fortran.

Usage

```
abs(x)
sqrt(x)
```

Arguments

`x` a numeric or [complex](#) vector or array.

Details

These are [internal generic primitive](#) functions: methods can be defined for them individually or via the [Math](#) group generic. For complex arguments (and the default method), `z`, `abs(z) == Mod(z)` and `sqrt(z) == z^0.5`.

`abs(x)` returns an [integer](#) vector when `x` is integer or [logical](#).

S4 methods

Both are S4 generic and members of the [Math](#) group generic.

[‘plotmath’](#) for the use of `sqrt` in plot annotation.

Examples

```
require(stats) # for spline
require(graphics)
xx <- -9:9
plot(xx, sqrt(abs(xx)), col = "red")
lines(spline(xx, sqrt(abs(xx)), n=101), col = "pink")
```

matmult

Matrix Multiplication

Description

Multiplies two matrices, if they are conformable. If one argument is a vector, it will be promoted to either a row or column matrix to make the two arguments conformable. If both are vectors of the same length, it will return the inner product (as a matrix).

Usage

```
x %*% y
```

Arguments

x, y numeric or complex matrices or vectors.

Details

When a vector is promoted to a matrix, its names are not promoted to row or column names, unlike [as.matrix](#).

Promotion of a vector to a 1-row or 1-column matrix happens when one of the two choices allows x and y to get conformable dimensions.

This operator is a generic function: methods can be written for it individually or via the [matrixOps](#) group generic function; it dispatches to S3 and S4 methods. Methods need to be written for a function that takes two arguments named x and y.

Value

A double or complex matrix product. Use [drop](#) to remove dimensions which have only one level.

Note

The propagation of NaN/Inf values, precision, and performance of matrix products can be controlled by [options](#)("matprod").

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

For matrix *cross* products, [crossprod\(\)](#) and [tcrossprod\(\)](#) are typically preferable. [matrix](#), [Arithmetic](#), [diag](#).

Examples

```
x <- 1:4
(z <- x %**% x)      # scalar ("inner") product (1 x 1 matrix)
drop(z)              # as scalar

y <- diag(x)
z <- matrix(1:12, ncol = 3, nrow = 4)
y %**% z
y %**% x
x %**% z
```

matrix

Matrices

Description

`matrix` creates a matrix from the given set of values.

`as.matrix` attempts to turn its argument into a matrix.

`is.matrix` tests if its argument is a (strict) matrix.

Usage

```
matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE,
        dimnames = NULL)

as.matrix(x, ...)
## S3 method for class 'data.frame'
as.matrix(x, rownames.force = NA, ...)

is.matrix(x)
```

Arguments

<code>data</code>	an optional data vector (including a list or expression vector). Non-atomic classed R objects are coerced by as.vector and all attributes discarded.
<code>nrow</code>	the desired number of rows.
<code>ncol</code>	the desired number of columns.
<code>byrow</code>	logical. If <code>FALSE</code> (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
<code>dimnames</code>	a dimnames attribute for the matrix: <code>NULL</code> or a list of length 2 giving the row and column names respectively. An empty list is treated as <code>NULL</code> , and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
<code>x</code>	an R object.
<code>...</code>	additional arguments to be passed to or from methods.
<code>rownames.force</code>	logical indicating if the resulting matrix should have character (rather than <code>NULL</code>) rownames . The default, <code>NA</code> , uses <code>NULL</code> rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.

Details

If one of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. If neither is given, a one-column matrix is returned.

If there are too few elements in `data` to fill the matrix, then the elements in `data` are recycled. If `data` has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

`is.matrix` returns TRUE if `x` is a vector and has a `"dim"` attribute of length 2 and FALSE otherwise. Note that a `data.frame` is **not** a matrix by this test. The function is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

`as.matrix` is a generic function. The method for data frames will return a character matrix if there is only atomic columns and any non-(numeric/logical/complex) column, applying `as.vector` to factors and `format` to other non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give a integer matrix, etc.

The default method for `as.matrix` calls `as.vector(x)`, and hence e.g. coerces factors to character vectors.

When coercing a vector, it produces a one-column matrix, and promotes the names (if any) of the vector to the rownames of the matrix.

`is.matrix` is a [primitive](#) function.

The `print` method for a matrix gives a rectangular layout with `dimnames` or indices. For a list matrix, the entries of length not one are printed in the form `'integer, 7'` indicating the type and length.

Note

If you just want to convert a vector to a matrix, something like

```
dim(x) <- c(nx, ny)
dimnames(x) <- list(row_names, col_names)
```

will avoid duplicating `x` and preserve `class(x)` which may be useful, e.g., for [Date](#) objects.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[data.matrix](#), which attempts to convert to a numeric matrix.

A matrix is the special case of a two-dimensional [array](#). `inherits(m, "array")` is true for a `matrix` `m`.

Examples

```
is.matrix(as.matrix(1:10))
!is.matrix(warpbreaks) # data.frame, NOT matrix!
warpbreaks[1:10,]
as.matrix(warpbreaks[1:10,]) # using as.matrix.data.frame(.) method

## Example of setting row and column names
```

```
mdat <- matrix(c(1,2,3, 11,12,13), nrow = 2, ncol = 3, byrow = TRUE,
               dimnames = list(c("row1", "row2"),
                               c("C.1", "C.2", "C.3")))
mdat
```

maxCol

Find Maximum Position in Matrix

Description

Find the maximum position for each row of a matrix, breaking ties at random.

Usage

```
max.col(m, ties.method = c("random", "first", "last"))
```

Arguments

`m` a numerical matrix.

`ties.method` a character string specifying how ties are handled, "random" by default; can be abbreviated; see 'Details'.

Details

When `ties.method = "random"`, as per default, ties are broken at random. In this case, the determination of a tie assumes that the entries are probabilities: there is a relative tolerance of 10^{-5} , relative to the largest (in magnitude, omitting infinity) entry in the row.

If `ties.method = "first"`, `max.col` returns the column number of the *first* of several maxima in every row, the same as `unname(apply(m, 1, which.max))` if `m` has no missing values. Correspondingly, `ties.method = "last"` returns the *last* of possibly several indices.

Value

index of a maximal value for each row, an integer vector of length `nrow(m)`.

See Also

`which.max` for vectors.

Examples

```
table(mc <- max.col(swiss)) # mostly "1" and "5", 5 x "2" and once "4"
swiss[unique(print(mr <- max.col(t(swiss)))) , ] # 3 33 45 45 33 6

set.seed(1) # reproducible example:
(mm <- rbind(x = round(2*stats::runif(12)),
             y = round(5*stats::runif(12)),
             z = round(8*stats::runif(12))))

## Not run:
      [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x      1      1      1      2      0      2      2      1      1      0      0      0
y      3      2      4      2      4      5      2      4      5      1      3      1
z      2      3      0      3      7      3      4      5      4      1      7      5

## End(Not run)
## column indices of all row maxima :
utils::str(lapply(1:3, function(i) which(mm[i,] == max(mm[i,]))))
max.col(mm) ; max.col(mm) # "random"
max.col(mm, "first") # -> 4 6 5
max.col(mm, "last") # -> 7 9 11
```

mean	<i>Arithmetic Mean</i>
------	------------------------

Description

Generic function for the (trimmed) arithmetic mean.

Usage

```
mean(x, ...)
```

```
## Default S3 method:
mean(x, trim = 0, na.rm = FALSE, ...)
```

Arguments

x	an R object. Currently there are methods for numeric/logical vectors and date , date-time and time interval objects. Complex vectors are allowed for <code>trim = 0</code> , only.
trim	the fraction (0 to 0.5) of observations to be trimmed from each end of <code>x</code> before the mean is computed. Values of <code>trim</code> outside that range are taken as the nearest endpoint.
na.rm	a logical evaluating to TRUE or FALSE indicating whether NA values should be stripped before the computation proceeds.
...	further arguments passed to or from other methods.

Value

If `trim` is zero (the default), the arithmetic mean of the values in `x` is computed, as a numeric or complex vector of length one. If `x` is not logical (coerced to numeric), numeric (including integer) or complex, `NA_real_` is returned, with a warning.

If `trim` is non-zero, a symmetrically trimmed mean is computed with a fraction of `trim` observations deleted from each end before the mean is computed.

Examples

```
x <- c(0:10, 50)
xm <- mean(x)
c(xm, mean(x, trim = 0.10))
```

memCompress

In-memory Compression and Decompression

Description

In-memory compression or decompression for raw vectors.

Usage

```
memCompress(from, type = c("gzip", "bzip2", "xz", "zstd", "none"))

memDecompress(from,
               type = c("unknown", "gzip", "bzip2", "xz", "zstd",
                       "none"), asChar = FALSE)
```

Arguments

<code>from</code>	raw vector. For <code>memCompress</code> , a character vector will be converted to a raw vector with character strings separated by <code>"\n"</code> . Types except <code>"bzip2"</code> support long raw vectors.
<code>type</code>	character string, the type of compression. May be abbreviated to a single letter, defaults to the first of the alternatives.
<code>asChar</code>	logical: should the result be converted to a character string? NB: character strings have a limit of $2^{31} - 1$ bytes, so raw vectors should be used for large inputs.

Details

`type = "none"` passes the input through unchanged, but may be useful if `type` is a variable.

`type = "unknown"` attempts to detect the type of compression applied (if any): this will always succeed for `bzip2` compression, and will succeed for other forms if there is a suitable header. If no type of compression is detected this is the same as `type = "none"` but a warning is given.

`gzip` compression uses whatever is the default compression level of the underlying library (usually 6). This supports the RFC 1950 format, sometimes known as ‘zlib’ format, for compression and decompression and for decompression only RFC 1952, the ‘gzip’ format (which wraps the ‘zlib’ format with a header and footer).

`bzip2` compression always adds a header ("BZh"). The underlying library only supports in-memory (de)compression of up to $2^{31} - 1$ elements. Compression is equivalent to `bzip2 -9` (the default).

`zstd` compression was introduced in R 4.5.0: it is an optional part of the R build and currently uses compression level 3 which gives a good compression ratio vs compression speed trade-off.

Compressing with `type = "xz"` is equivalent to compressing a file with `xz -9e` (including adding the ‘magic’ header): decompression should cope with the contents of any file compressed by `xz` version 4.999 and later, as well as by some versions of `lzma`. There are other versions, in particular ‘raw’ streams, that are not currently handled.

All the types of compression can expand the input: for "gzip" and "bzip2" the maximum expansion is known and so `memCompress` can always allocate sufficient space. For "xz" it is possible (but extremely unlikely) that compression will fail if the output would have been too large.

Value

A raw vector or a character string (if `asChar = TRUE`).

libdeflate

Support for the `libdeflate` library was added for R 4.4.0. It uses different code for the RFC 1950 ‘zlib’ format (and RFC 1952 for decompression), expected to be substantially faster than using the reference (or system) `zlib` library. It is used for `type = "gzip"` if available.

The headers and sources can be downloaded from <https://github.com/ebiggers/libdeflate> and pre-built versions are available for most Linux distributions. It is used for binary Windows and macOS distributions.

If it is used by an R build and if so which version can be seen from `extSoftVersion()`.

Examples

```

txt <- readLines(file.path(R.home("doc"), "COPYING"))
sum(nchar(txt))
txt.gz <- memCompress(txt, "g") # "gzip", the default
length(txt.gz)
txt2 <- strsplit(memDecompress(txt.gz, "g", asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt2))
## as from R 4.4.0 this is detected if not specified.
txt2b <- strsplit(memDecompress(txt.gz, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt2b, txt2))

txt.bz2 <- memCompress(txt, "b")
length(txt.bz2)
## can auto-detect bzip2:
txt3 <- strsplit(memDecompress(txt.bz2, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt3))

## xz compression is only worthwhile for large objects
txt.xz <- memCompress(txt, "x")
length(txt.xz)
txt3 <- strsplit(memDecompress(txt.xz, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt3))

## test decompressing a gzip-ed file
tf <- tempfile(fileext = ".gz")
con <- gzfile(tf, "w")
writeLines(txt, con)
close(con)
(nf <- file.size(tf))
# if (nzchar(Sys.which("file"))) system2("file", tf)
foo <- readBin(tf, "raw", n = nf)
unlink(tf)
## will detect the gzip header and choose type = "gzip"
txt3 <- strsplit(memDecompress(foo, asChar = TRUE), "\n")[[1]]
stopifnot(identical(txt, txt3))

```

memlimits

*Query and Set Heap Size Limits***Description**

Query and set the maximal size of the vector heap and the maximal number of heap nodes for the current R process.

Usage

```

mem.maxVSize(vsize = 0)
mem.maxNSize(nsize = 0)

```

Arguments

vsize	numeric; new size limit in Mb.
nsize	numeric; new maximal node number.

Details

New limits lower than current usage are ignored. Specifying a size of `Inf` sets the limit to the maximal possible value for the platform.

The default maximal values are unlimited on most platforms, but can be adjusted using environment variables as described in [Memory](#). On macOS a lower default vector heap limit is used to protect against the R process being killed when macOS over-commits memory.

Adjusting the maximal number of nodes is rarely necessary. Adjusting the vector heap size limit can be useful on macOS in particular but should be done with caution.

Value

The current or new value, in Mb for `mem.maxVSize`. `Inf` is returned if the current value is unlimited.

See Also

[Memory](#).

Memory

Memory Available for Data Storage

Description

How R manages its workspace.

Details

R has a variable-sized workspace. There are (rarely-used) command-line options to control its minimum size, but no longer any to control the maximum size.

R maintains separate areas for fixed and variable sized objects. The first of these is allocated as an array of *cons cells* (Lisp programmers will know what they are, others may think of them as the building blocks of the language itself, parse trees, etc.), and the second are thrown on a *heap* of ‘Vcells’ of 8 bytes each. Each cons cell occupies 28 bytes on a 32-bit build of R, (usually) 56 bytes on a 64-bit build.

The default values are (currently) an initial setting of 350k cons cells and 6Mb of vector heap. Note that the areas are not actually allocated initially: rather these values are the sizes for triggering garbage collection. These values can be set by the command line options ‘`--min-nsz`’ and ‘`--min-vsz`’ (or if they are not used, the environment variables `R_NSZ` and `R_VSZ`) when R is started. Thereafter R will grow or shrink the areas depending on usage, never decreasing below the initial values. The maximal vector heap size can be set with the environment variable `R_MAX_VSZ`. An attempt to set a lower maximum than the current usage is ignored. Vector heap limits are given in bytes.

How much time R spends in the garbage collector will depend on these initial settings and on the trade-off the memory manager makes, when memory fills up, between collecting garbage to free up unused memory and growing these areas. The strategy used for growth can be specified by setting the environment variable `R_GC_MEM_GROW` to an integer value between 0 and 3. This variable is read at start-up. Higher values grow the heap more aggressively, thus reducing garbage collection time but using more memory.

You can find out the current memory consumption (the heap and cons cells used as numbers and megabytes) by typing `gc()` at the R prompt. Note that following `gcinfo(TRUE)`, automatic garbage collection always prints memory use statistics.

The command-line option `--max-ppsize` controls the maximum size of the pointer protection stack. This defaults to 50000, but can be increased to allow deep recursion or large and complicated calculations to be done. *Note* that parts of the garbage collection process goes through the full reserved pointer protection stack and hence becomes slower when the size is increased. Currently the maximum value accepted is 500000.

See Also

“Invoking R from the command line” in *An Introduction to R* for more command-line options.

[Memory-limits](#) for the design limitations.

`gc` for information on the garbage collector and total memory usage, `object.size(a)` for the (approximate) size of R object `a`, `memory.profile` for profiling the usage of cons cells.

Memory-limits

Memory Limits in R

Description

R holds objects it is using in virtual memory. This help file documents the current design limitations on large objects: these differ between 32-bit and 64-bit builds of R.

Details

Currently R runs on 32- and 64-bit operating systems, and most 64-bit OSes (including Linux, Solaris, Windows and macOS) can run either 32- or 64-bit builds of R. The memory limits depends mainly on the build, but for a 32-bit build of R on Windows they also depend on the underlying OS version.

R holds all objects in virtual memory, and there are limits based on the amount of memory that can be used by all objects:

- There may be limits on the size of the heap and the number of cons cells allowed – see [Memory](#) – but these are usually not imposed.
- There is a limit on the (user) address space of a single process such as the R executable. This is system-specific, and can depend on the executable.
- The environment may impose limitations on the resources available to a single process: Windows’ versions of R do so directly.

Error messages beginning `‘cannot allocate vector of size’` indicate a failure to obtain memory, either because the size exceeded the address-space limit for a process or, more likely, because the system was unable to provide the memory. Note that on a 32-bit build there may well be enough free memory available, but not a large enough contiguous block of address space into which to map it.

There are also limits on individual objects. The storage space cannot exceed the address limit, and if you try to exceed that limit, the error message begins `‘cannot allocate vector of length’`. The number of bytes in a character string is limited to $2^{31} - 1 \approx 2 \cdot 10^9$, which is also the limit on each dimension of an array.

Unix

The address-space limit is system-specific: 32-bit OSes imposes a limit of no more than 4Gb: it is often 3Gb. Running 32-bit executables on a 64-bit OS will have similar limits: 64-bit executables will have an essentially infinite system-specific limit (e.g., 128Tb for Linux on x86_64 CPUs).

See the OS/shell's help on commands such as `limit` or `ulimit` for how to impose limitations on the resources available to a single process. For example a `bash` user could use

```
ulimit -t 600 -v 4000000
```

whereas a `csch` user might use

```
limit cputime 10m
limit vmemoryuse 4096m
```

to limit a process to 10 minutes of CPU time and (around) 4Gb of virtual memory. (There are other options to set the RAM in use, but they are not generally honoured.)

Windows

The address-space limit is 2Gb under 32-bit Windows unless the OS's default has been changed to allow more (up to 3Gb). See <https://learn.microsoft.com/en-gb/windows/desktop/Memory/physical-address-extension> and <https://learn.microsoft.com/en-gb/windows/desktop/Memory/4-gigabyte-tuning>. Under most 64-bit versions of Windows the limit for a 32-bit build of R is 4Gb: for the oldest ones it is 2Gb. The limit for a 64-bit build of R (imposed by the OS) is 8Tb.

It is not normally possible to allocate as much as 2Gb to a single vector in a 32-bit build of R even on 64-bit Windows because of preallocations by Windows in the middle of the address space.

See Also

`object.size(a)` for the (approximate) size of R object `a`.

memory.profile

Profile the Usage of Cons Cells

Description

Lists the usage of the cons cells by `SEXP` type.

Usage

```
memory.profile()
```

Details

The current types and their uses are listed in the include file `'Rinternals.h'`.

Value

A vector of counts, named by the types. See `typeof` for an explanation of types.

See Also

[gc](#) for the overall usage of cons cells. [Rprofmem](#) and [tracemem](#) allow memory profiling of specific code or objects, but need to be enabled at compile time.

Examples

```
memory.profile()
```

merge	<i>Merge Two Data Frames</i>
-------	------------------------------

Description

Merge two data frames by common columns or row names, or do other versions of database *join* operations.

Usage

```
merge(x, y, ...)

## Default S3 method:
merge(x, y, ...)

## S3 method for class 'data.frame'
merge(x, y, by = intersect(names(x), names(y)),
      by.x = by, by.y = by, all = FALSE, all.x = all, all.y = all,
      sort = TRUE, suffixes = c(".x", ".y"), no.dups = TRUE,
      incomparables = NULL, ...)
```

Arguments

<code>x, y</code>	data frames, or objects to be coerced to one.
<code>by, by.x, by.y</code>	specifications of the columns used for merging. See ‘Details’.
<code>all</code>	logical; <code>all = L</code> is shorthand for <code>all.x = L</code> and <code>all.y = L</code> , where <code>L</code> is either TRUE or FALSE .
<code>all.x</code>	logical; if TRUE , then extra rows will be added to the output, one for each row in <code>x</code> that has no matching row in <code>y</code> . These rows will have <code>NA</code> s in those columns that are usually filled with values from <code>y</code> . The default is FALSE , so that only rows with data from both <code>x</code> and <code>y</code> are included in the output.
<code>all.y</code>	logical; analogous to <code>all.x</code> .
<code>sort</code>	logical. Should the result be sorted on the <code>by</code> columns?
<code>suffixes</code>	a character vector of length 2 specifying the suffixes to be used for making unique the names of columns in the result which are not used for merging (appearing in <code>by</code> etc).
<code>no.dups</code>	logical indicating that <code>suffixes</code> are appended in more cases to avoid duplicated column names in the result. This was implicitly false before R version 3.5.0.
<code>incomparables</code>	values which cannot be matched. See match . This is intended to be used for merging on one column, so these are incomparable values of that column.
<code>...</code>	arguments to be passed to or from methods.

Details

`merge` is a generic function whose principal method is for data frames: the default method coerces its arguments to data frames and calls the `"data.frame"` method.

By default the data frames are merged on the columns with names they both have, but separate specifications of the columns can be given by `by.x` and `by.y`. The rows in the two data frames that match on the specified columns are extracted, and joined together. If there is more than one match, all possible matches contribute one row each. For the precise meaning of ‘match’, see [match](#).

Columns to merge on can be specified by name, number or by a logical vector: the name `"row.names"` or the number 0 specifies the row names. If specified by name it must correspond uniquely to a named column in the input.

If `by` or both `by.x` and `by.y` are of length 0 (a length zero vector or `NULL`), the result, `r`, is the *Cartesian product* of `x` and `y`, i.e., $\dim(r) = c(\text{nrow}(x) * \text{nrow}(y), \text{ncol}(x) + \text{ncol}(y))$.

If `all.x` is true, all the non matching cases of `x` are appended to the result as well, with NA filled in the corresponding columns of `y`; analogously for `all.y`.

If the columns in the data frames not used in merging have any common names, these have suffixes (`".x"` and `".y"` by default) appended to try to make the names of the result unique. If this is not possible, an error is thrown.

If a `by.x` column name matches one of `y`, and if `no.dups` is true (as by default), the `y` version gets suffixed as well, avoiding duplicate column names in the result.

The complexity of the algorithm used is proportional to the length of the answer.

In SQL database terminology, the default value of `all = FALSE` gives a *natural join*, a special case of an *inner join*. Specifying `all.x = TRUE` gives a *left (outer) join*, `all.y = TRUE` a *right (outer) join*, and both (`all = TRUE`) a *(full) outer join*. DBMSes do not match `NULL` records, equivalent to `incomparables = NA` in R.

Value

A data frame. The rows are by default lexicographically sorted on the common columns, but for `sort = FALSE` are in an unspecified order. The columns are the common columns followed by the remaining columns in `x` and then those in `y`. If the matching involved row names, an extra character column called `Row.names` is added at the left, and in all cases the result has ‘automatic’ row names.

Note

This is intended to work with data frames with vector-like columns: some aspects work with data frames containing matrices, but not all.

Currently long vectors are not accepted for inputs, which are thus restricted to less than 2^{31} rows. That restriction also applies to the result for 32-bit platforms.

See Also

[dendrogram](#) for a class which has a `merge` method.

Examples

```

authors <- data.frame(
  surname = c("Tukey", "Venables", "Tierney", "Ripley", "McNeil"),
  nationality = c("US", "Australia", "US", "UK", "Australia"),
  deceased = c("yes", rep("no", 4)))
authorN <- within(authors, { name <- surname; rm(surname) })
books <- data.frame(
  name = c("Tukey", "Venables", "Tierney",
           "Ripley", "Ripley", "McNeil", "R Core"),
  title = c("Exploratory Data Analysis",
            "Modern Applied Statistics ...",
            "LISP-STAT",
            "Spatial Statistics", "Stochastic Simulation",
            "Interactive Data Analysis",
            "An Introduction to R"),
  other.author = c(NA, "Ripley", NA, NA, NA, NA,
                  "Venables & Smith"))

(m0 <- merge(authorN, books))
(m1 <- merge(authors, books, by.x = "surname", by.y = "name"))
m2 <- merge(books, authors, by.x = "name", by.y = "surname")
stopifnot(exprs = {
  identical(m0, m2[, names(m0)])
  as.character(m1[, 1]) == as.character(m2[, 1])
  all.equal(m1[, -1], m2[, -1][ names(m1)[-1] ])
  identical(dim(merge(m1, m2, by = NULL)),
            c(nrow(m1)*nrow(m2), ncol(m1)+ncol(m2)))
})

## "R core" is missing from authors and appears only here :
merge(authors, books, by.x = "surname", by.y = "name", all = TRUE)

## example of using 'incomparables'
x <- data.frame(k1 = c(NA, NA, 3, 4, 5), k2 = c(1, NA, NA, 4, 5), data = 1:5)
y <- data.frame(k1 = c(NA, 2, NA, 4, 5), k2 = c(NA, NA, 3, 4, 5), data = 1:5)
merge(x, y, by = c("k1", "k2")) # NAs match
merge(x, y, by = "k1") # NAs match, so 6 rows
merge(x, y, by = "k2", incomparables = NA) # 2 rows

```

message

Diagnostic Messages

Description

Generate a diagnostic message from its arguments.

Usage

```

message(..., domain = NULL, appendLF = TRUE)
suppressMessages(expr, classes = "message")

packageStartupMessage(..., domain = NULL, appendLF = TRUE)
suppressPackageStartupMessages(expr)

```

```
.makeMessage(..., domain = NULL, appendLF = FALSE)
```

Arguments

<code>...</code>	zero or more objects which can be coerced to character (and which are pasted together with no separator) or (for <code>message</code> only) a single condition object.
<code>domain</code>	see gettext . If NA, messages will not be translated, see also the note in stop .
<code>appendLF</code>	logical: should messages given as a character string have a newline appended?
<code>expr</code>	expression to evaluate.
<code>classes</code>	character, indicating which classes of messages should be suppressed.

Details

`message` is used for generating ‘simple’ diagnostic messages which are neither warnings nor errors, but nevertheless represented as conditions. Unlike warnings and errors, a final newline is regarded as part of the message, and is optional. The default handler sends the message to the `stderr()` [connection](#).

If a condition object is supplied to `message` it should be the only argument, and further arguments will be ignored, with a warning.

While the message is being processed, a `muffleMessage` restart is available.

`suppressMessages` evaluates its expression in a context that ignores all ‘simple’ diagnostic messages.

`packageStartupMessage` is a variant whose messages can be suppressed separately by `suppressPackageStartupMessages`. (They are still messages, so can be suppressed by `suppressMessages`.)

`.makeMessage` is a utility used by `message`, `warning` and `stop` to generate a text message from the `...` arguments by possible translation (see [gettext](#)) and concatenation (with no separator).

See Also

[warning](#) and [stop](#) for generating warnings and errors; [conditions](#) for condition handling and recovery.

[gettext](#) for the mechanisms for the automated translation of text.

Examples

```
message("ABC", "DEF")
suppressMessages(message("ABC"))

testit <- function() {
  message("testing package startup messages")
  packageStartupMessage("initializing ...", appendLF = FALSE)
  Sys.sleep(1)
  packageStartupMessage(" done")
}

testit()
suppressPackageStartupMessages(testit())
suppressMessages(testit())
```

missing

Does a Formal Argument have a Value?

Description

`missing` can be used to test whether a value was specified as an argument to a function.

Usage

```
missing(x)
```

Arguments

`x` a formal argument.

Details

`missing(x)` is only reliable if `x` has not been altered since entering the function: in particular it will *always* be false after `x <- match.arg(x)`.

The example shows how a plotting function can be written to work with either a pair of vectors giving `x` and `y` coordinates of points to be plotted or a single vector giving `y` values to be plotted against their indices.

Currently `missing` can only be used in the immediate body of the function that defines the argument, not in the body of a nested function or a `local` call. This may change in the future.

This is a ‘special’ [primitive](#) function: it must not evaluate its argument.

See Also

[substitute](#) for argument expression; [NA](#) for missing values in data.

Examples

```
myplot <- function(x, y) {  
  if(missing(y)) {  
    y <- x  
    x <- 1:length(y)  
  }  
  plot(x, y)  
}
```

mode

*The (Storage) Mode of an Object***Description**

Get or set the ‘mode’ (a kind of ‘type’), or the storage mode of an R object.

Usage

```
mode(x)
mode(x) <- value
storage.mode(x)
storage.mode(x) <- value
```

Arguments

<code>x</code>	any R object.
<code>value</code>	a character string giving the desired mode or ‘storage mode’ (type) of the object.

Details

Both `mode` and `storage.mode` return a character string giving the (storage) mode of the object — often the same — both relying on the output of `typeof(x)`, see the example below.

`mode(x) <- "newmode"` changes the mode of object `x` to `newmode`. This is only supported if there is an appropriate `as.newmode` function, for example "logical", "integer", "double", "complex", "raw", "character", "list", "expression", "name", "symbol" and "function". Attributes are preserved (but see below).

`storage.mode(x) <- "newmode"` is a more efficient [primitive](#) version of `mode<-`, which works for "newmode" which is one of the internal types (see `typeof`), but not for "single". Attributes are preserved.

As storage mode "single" is only a pseudo-mode in R, it will not be reported by `mode` or `storage.mode`: use `attr(object, "Csingl")` to examine this. However, `mode<-` can be used to set the mode to "single", which sets the real mode to "double" and the "Csingl" attribute to TRUE. Setting any other mode will remove this attribute.

Note (in the examples below) that some [calls](#) have mode "(" which is S compatible.

Mode names

Modes have the same set of names as types (see `typeof`) except that

- types "integer" and "double" are returned as "numeric".
- types "special", "builtin" and "closure" are returned as "function".
- type "symbol" is called mode "name".
- type "language" is returned as "(" or "call".

See Also

`typeof` for the R-internal ‘mode’ or ‘type’, `type.convert`, `attributes`.

Examples

```
require(stats)

sapply(options(), mode)

cex3 <- c("NULL", "1", "1:1", "1i", "list(1)", "data.frame(x = 1)",
  "pairlist(pi)", "c", "lm", "formals(lm)[[1]]", "formals(lm)[[2]]",
  "y ~ x", "expression(1)[[1]]", "(y ~ x)[[1]]",
  "expression(x <- pi)[[1]][[1]]")
lex3 <- sapply(cex3, function(x) eval(str2lang(x)))
mex3 <- t(sapply(lex3,
  function(x) c(typeof(x), storage.mode(x), mode(x))))
dimnames(mex3) <- list(cex3, c("typeof(.)", "storage.mode(.)", "mode(.)"))
mex3

## This also makes a local copy of 'pi':
storage.mode(pi) <- "complex"
storage.mode(pi)
rm(pi)
```

mtfrm

*Auxiliary Function for Matching***Description**

Transform objects for matching via `match()`, think “match form” → “mtfrm”. **base** provides the S3 generic and a default plus “`POSIXct`” and “`POSIXlt`” methods.

Usage

```
mtfrm(x)
```

Arguments

`x` an R object

Details

Matching via `match` will use `mtfrm` to transform internally classed objects (see `is.object`) to a vector representation appropriate for matching. The default method performs `as.character` if this preserves the length.

Ideally, methods for `mtfrm` should ensure that comparisons of same-classed objects via `match` are consistent with those employed by methods for `duplicated/unique` and `==/!=` (where applicable).

Value

A vector of the same length as `x`.

NA	<i>'Not Available' / Missing Values</i>
----	---

Description

NA is a logical constant of length 1 which contains a missing value indicator. NA can be coerced to any other vector type except raw. There are also constants `NA_integer_`, `NA_real_`, `NA_complex_` and `NA_character_` of the other atomic vector types which support missing values: all of these are [reserved](#) words in the R language.

The generic function `is.na` indicates which elements are missing.

The generic function `is.na<-` sets elements to NA.

The generic function `anyNA` implements `any(is.na(x))` in a possibly faster way (especially for atomic vectors).

Usage

```
NA
is.na(x)
anyNA(x, recursive = FALSE)

## S3 method for class 'data.frame'
is.na(x)

is.na(x) <- value
```

Arguments

<code>x</code>	an R object to be tested: the default method for <code>is.na</code> and <code>anyNA</code> handle atomic vectors, lists, pairlists, and NULL.
<code>recursive</code>	logical: should <code>anyNA</code> be applied recursively to lists and pairlists?
<code>value</code>	a suitable index vector for use with <code>x</code> .

Details

The NA of character type is distinct from the string "NA". Programmers who need to specify an explicit missing string should use `NA_character_` (rather than "NA") or set elements to NA using `is.na<-`.

`is.na` and `anyNA` are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

Function `is.na<-` may provide a safer way to set missingness. It behaves differently for factors, for example.

Numerical computations using NA will normally result in NA: a possible exception is where NaN is also involved, in which case either might result (which may depend on the R platform). However, this is not guaranteed and future CPUs and/or compilers may behave differently. Dynamic binary translation may also impact this behavior (with valgrind, computations using NA may result in NaN even when no NaN is involved).

Logical computations treat NA as a missing TRUE/FALSE value, and so may return TRUE or FALSE if the expression does not depend on the NA operand.

The default method for `anyNA` handles atomic vectors without a class and `NULL`. It calls `any(is.na(x))` on objects with classes and for `recursive = FALSE`, on lists and pairlists.

Value

The default method for `is.na` applied to an atomic vector returns a logical vector of the same length as its argument `x`, containing `TRUE` for those elements marked `NA` or, for numeric or complex vectors, `NaN`, and `FALSE` otherwise. (A complex value is regarded as `NA` if either its real or imaginary part is `NA` or `NaN`.) `dim`, `dimnames` and `names` attributes are copied to the result.

The default methods also work for lists and pairlists:

For `is.na`, elementwise the result is `false` unless that element is a length-one atomic vector and the single element of that vector is regarded as `NA` or `NaN` (note that any `is.na` method for the class of the element is ignored).

`anyNA(recursive = FALSE)` works the same way as `is.na`; `anyNA(recursive = TRUE)` applies `anyNA` (with method dispatch) to each element.

The data frame method for `is.na` returns a logical matrix with the same dimensions as the data frame, and with `dimnames` taken from the row and column names of the data frame.

`anyNA(NULL)` is `false`; `is.na(NULL)` is `logical(0)` (no longer warning since R version 3.5.0).

`NaN`, `is.nan`, etc., and the utility function `complete.cases`.

`na.action`, `na.omit`, `na.fail` on how methods can be tuned to deal with missing values.

Examples

```
is.na(c(1, NA))      #> FALSE TRUE
is.na(paste(c(1, NA))) #> FALSE FALSE

(xx <- c(0:4))
is.na(xx) <- c(2, 4)
xx          #> 0 NA 2 NA 4
anyNA(xx)   # TRUE

# Some logical operations do not return NA
c(TRUE, FALSE) & NA
c(TRUE, FALSE) | NA

## Measure speed difference in a favourable case:
## the difference depends on the platform, on most ca 3x.
x <- 1:10000; x[5000] <- NaN # coerces x to be double
if(require("microbenchmark")) { # does not work reliably on all platforms
  print(microbenchmark(any(is.na(x)), anyNA(x)))
} else {
  nSim <- 2^13
```

```

    print(rbind(is.na = system.time(replicate(nSim, any(is.na(x)))),
               anyNA = system.time(replicate(nSim, anyNA(x)))))
  }

## anyNA() can work recursively with list():
LL <- list(1:5, c(NA, 5:8), c("A", "NA"), c("a", NA_character_))
L2 <- LL[c(1,3)]
sapply(LL, anyNA); c(anyNA(LL), anyNA(LL, TRUE))
sapply(L2, anyNA); c(anyNA(L2), anyNA(L2, TRUE))

## ... lists, and hence data frames, too:
dN <- dd <- USJudgeRatings; dN[3,6] <- NA
anyNA(dd) # FALSE
anyNA(dN) # TRUE

```

name

Names and Symbols

Description

A ‘name’ (also known as a ‘symbol’) is a way to refer to R objects by name (rather than the value of the object, if any, bound to that name).

`as.name` and `as.symbol` are identical: they attempt to coerce the argument to a name.

`is.symbol` and the identical `is.name` return TRUE or FALSE depending on whether the argument is a name or not.

Usage

```

as.symbol(x)
is.symbol(x)

```

```

as.name(x)
is.name(x)

```

Arguments

`x` object to be coerced or tested.

Details

Names are limited to 10,000 bytes (and were to 256 bytes in versions of R before 2.13.0).

`as.name` first coerces its argument internally to a character vector (so methods for `as.character` are not used). It then takes the first element and provided it is not "", returns a symbol of that name (and if the element is `NA_character_`, the name is ``NA``).

`as.name` is implemented as `as.vector(x, "symbol")`, and hence will dispatch methods for the generic function `as.vector`.

`is.name` and `is.symbol` are [primitive](#) functions.

Value

For `as.name` and `as.symbol`, an R object of type "symbol" (see `typeof`).

For `is.name` and `is.symbol`, a length-one logical vector with value TRUE or FALSE.

Note

The term ‘symbol’ is from the LISP background of R, whereas ‘name’ has been the standard S term for this.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`call`, `is.language`. For the internal object mode, `typeof`.

`plotmath` for another use of ‘symbol’.

Examples

```
an <- as.name("arrg")
is.name(an) # TRUE
mode(an)    # name
typeof(an)  # symbol
```

names

The Names of an Object

Description

Functions to get or set the names of an object.

Usage

```
names(x)
names(x) <- value
```

Arguments

`x` an R object.

`value` a character vector of up to the same length as `x`, or NULL.

Details

`names` is a generic accessor function, and `names<-` is a generic replacement function. The default methods get and set the "names" attribute of a vector (including a list) or pairlist.

For an `environment` `env`, `names(env)` gives the names of the corresponding list, i.e., `names(as.list(env, all.names = TRUE))` which are also given by `ls(env, all.names = TRUE, sorted = FALSE)`. If the environment is used as a hash table, `names(env)` are its "keys".

If `value` is shorter than `x`, it is extended by character `NA`s to the length of `x`.

It is possible to update just part of the names attribute via the general rules: see the examples. This works because the expression there is evaluated as `z <- "names<-"(z, "[<-"(names(z), 3, "c2"))`.

The name `" "` is special: it is used to indicate that there is no name associated with an element of a (atomic or generic) vector. Subscripting by `" "` will match nothing (not even elements which have no name).

A name can be character `NA`, but such a name will never be matched and is likely to lead to confusion.

Both are `primitive` functions.

Value

For `names`, `NULL` or a character vector of the same length as `x`. (`NULL` is given if the object has no names, including for objects of types which cannot have names.) For an environment, the length is the number of objects in the environment but the order of the names is arbitrary.

For `names<-`, the updated object. (Note that the value of `names(x) <- value` is that of the assignment, `value`, not the return value from the left-hand side.)

Note

For vectors, the names are one of the `attributes` with restrictions on the possible values. For pairlists, the names are the tags and converted to and from a character vector.

For a one-dimensional array the `names` attribute really is `dimnames[[1]]`.

Formally classed aka "S4" objects typically have `slotNames()` (and no `names()`).

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`slotNames`, `dimnames`.

Examples

```
# print the names attribute of the islands data set
names(islands)

# remove the names attribute
names(islands) <- NULL
islands
rm(islands) # remove the copy made
```

```

z <- list(a = 1, b = "c", c = 1:3)
names(z)
# change just the name of the third element.
names(z)[3] <- "c2"
z

z <- 1:3
names(z)
## assign just one name
names(z)[2] <- "b"
z

```

nargs

The Number of Arguments to a Function

Description

When used inside a function body, `nargs` returns the number of arguments supplied to that function, *including* positional arguments left blank.

Usage

```
nargs()
```

Details

The count includes empty (missing) arguments, so that `foo(x, , z)` will be considered to have three arguments (see ‘Examples’). This can occur in rather indirect ways, so for example `x[]` might dispatch a call to ``[.some_method`(x, )` which is considered to have two arguments.

This is a [primitive](#) function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

[args](#), [formals](#) and [sys.call](#).

Examples

```

tst <- function(a, b = 3, ...) {nargs()}
tst() # 0
tst(clicketyclack) # 1 (even non-existing)
tst(c1, a2, rr3) # 3

foo <- function(x, y, z, w) {
  cat("call was ", deparse(match.call()), "\n", sep = "")
  nargs()
}

```

```

}
foo()      # 0
foo(, , 3) # 3
foo(z = 3) # 1, even though this is the same call

nargs()    # not really meaningful

```

nchar

Count the Number of Characters (or Bytes or Width)

Description

`nchar` takes a character vector as an argument and returns a vector whose elements contain the sizes of the corresponding elements of `x`. Internally, it is a generic, for which methods can be defined (see [InternalMethods](#)).

`nzchar` is a fast way to find out if elements of a character vector are non-empty strings.

Usage

```
nchar(x, type = "chars", allowNA = FALSE, keepNA = NA)
```

```
nzchar(x, keepNA = FALSE)
```

Arguments

<code>x</code>	character vector, or a vector to be coerced to a character vector. Giving a factor is an error.
<code>type</code>	character string: partial matching to one of <code>c("bytes", "chars", "width")</code> . See ‘Details’.
<code>allowNA</code>	logical: should NA be returned for invalid multibyte strings or "bytes"-encoded strings (rather than throwing an error)?
<code>keepNA</code>	logical: should NA be returned when <code>x</code> is NA? If false, <code>nchar()</code> returns 2, as that is the number of printing characters used when strings are written to output, and <code>nzchar()</code> is TRUE. The default for <code>nchar()</code> , NA, means to use <code>keepNA = TRUE</code> unless <code>type</code> is "width".

Details

The ‘size’ of a character string can be measured in one of three ways (corresponding to the `type` argument):

`bytes` The number of bytes needed to store the string (plus in C a final terminator which is not counted).

`chars` The number of characters.

`width` The number of columns `cat` will use to print the string in a monospaced font. The same as `chars` if this cannot be calculated.

These will often be the same, and usually will be in single-byte locales (but note how `type` determines the default for `keepNA`). There will be differences between the first two with multibyte character sequences, e.g. in UTF-8 locales.

The internal equivalent of the default method of `as.character` is performed on `x` (so there is no method dispatch). If you want to operate on non-vector objects passing them through `deparse` first will be required.

Value

For `nchar`, an integer vector giving the sizes of each element. For missing values (i.e., `NA`, i.e., `NA_character_`), `nchar()` returns `NA_integer_` if `keepNA` is true, and 2, the number of printing characters, if false.

`type = "width"` gives (an approximation to) the number of columns used in printing each element in a terminal font, taking into account double-width, zero-width and ‘composing’ characters. The approximation is likely to be poor when there are unassigned or non-printing characters.

If `allowNA = TRUE` and an element is detected as invalid in a multi-byte character set such as UTF-8, its number of characters and the width will be `NA`. Otherwise the number of characters will be non-negative, so `!is.na(nchar(x, "chars", TRUE))` is a test of validity.

A character string marked with “bytes” encoding (see [Encoding](#)) has a number of bytes, but neither a known number of characters nor a width, so the latter two types are `NA` if `allowNA = TRUE`, otherwise an error.

Names, dims and dimnames are copied from the input.

For `nzchar`, a logical vector of the same length as `x`, true if and only if the element has non-zero size; if the element is `NA`, `nzchar()` is true when `keepNA` is false (the default) or `NA`, and `NA` otherwise.

Note

This does **not** by default give the number of characters that will be used to `print()` the string. Use `encodeString` to find that. Where character strings have been marked as UTF-8, the number of characters and widths will be computed in UTF-8, even though printing may use escapes such as ‘<U+2642>’ in a non-UTF-8 locale.

The concept of ‘width’ is a slippery one even in a monospaced font. Some human languages have the concept of *combining* characters, in which two or more characters are rendered together: an example would be “y\u306”, which is two characters of width one: combining characters are given width zero, and there are other zero-width characters such as the zero-width space “\u200b”.

Some East Asian languages have ‘wide’ characters, ideographs which are conventionally printed across two columns when mixed with ASCII and other ‘narrow’ characters in those languages. The problem is that whether a computer prints wide characters over two or one columns depends on the font, with it not being uncommon to use two columns in a font intended for East Asian users and a single column in a ‘Western’ font. Unicode has encodings for ‘fullwidth’ versions of ASCII characters and ‘halfwidth’ versions of Katakana (Japanese) and Hangul (Korean) characters. Then there is the ‘East Asian Ambiguous class’ (Greek, Cyrillic, signs, some accented Latin chars, etc), for which the historical practice was to use two columns in East Asia and one elsewhere. The width quoted by `nchar` for characters in that class (and some others) depends on the locale, being one except in some East Asian locales on some OSes (notably Windows).

Control characters are usually given width zero: this includes CR and LF. Computing the width of a string containing control characters should be avoided (and may depend on the OS and R version).

Examples

```
x <- c("asfef", "qwerty", "yuiop[", "b", "stuff.blah.yech")
nchar(x)
# 5 6 6 1 15

nchar(deparse(mean))
# 18 17 <-- unless mean differs from base::mean

## NA behaviour as function of keepNA=* :
logi <- setNames(c(FALSE, NA, TRUE))
sapply(logi, \(k) data.frame(nchar = nchar(NA, keepNA=k),
                             nzchar = nzchar(NA, keepNA=k)))

x[3] <- NA; x
nchar(x, keepNA= TRUE) # 5 6 NA 1 15
nchar(x, keepNA=FALSE) # 5 6 2 1 15
stopifnot(identical(nchar(x), nchar(x, keepNA= TRUE)),
           identical(nchar(x, "w"), nchar(x, keepNA=FALSE)),
           identical(is.na(x), is.na(nchar(x))))

## 'nchar()' for all three types :
nchars <- function(x, ...)
  vapply(c("chars", "bytes", "width"),
         function(tp) nchar(x, tp, ...), integer(length(x)))

nchars("\u200b") # in R versions (>= 2015-09-xx):
## chars bytes width
##      1      3      0

data.frame(x, nchars(x)) ## all three types : same unless for NA
## force the same by forcing 'keepNA':
(ncT <- nchars(x, keepNA = TRUE)) ## .... NA NA NA ....
(ncF <- nchars(x, keepNA = FALSE)) ## .... 2 2 2 ....
stopifnot(apply(ncT, 1, function(.) length(unique(.))) == 1,
          apply(ncF, 1, function(.) length(unique(.))) == 1)
```

nlevels

The Number of Levels of a Factor

Description

Return the number of levels which its argument has.

Usage

```
nlevels(x)
```

Arguments

x an object, usually a factor.

Details

This is usually applied to a factor, but other objects can have levels.

The actual factor levels (if they exist) can be obtained with the `levels` function.

Value

The length of `levels(x)`, which is zero if `x` has no levels.

See Also

`levels`, `factor`.

Examples

```
nlevels(gl(3, 7)) # = 3
```

noquote

Class for 'no quote' Printing of Character Strings

Description

Print character strings without quotes.

Usage

```
noquote(obj, right = FALSE)

## S3 method for class 'noquote'
print(x, quote = FALSE, right = FALSE, ...)

## S3 method for class 'noquote'
c(..., recursive = FALSE)
```

Arguments

<code>obj</code>	any R object, typically a vector of <code>character</code> strings.
<code>right</code>	optional <code>logical</code> eventually to be passed to <code>print()</code> , used by <code>print.default()</code> , indicating whether or not strings should be right aligned.
<code>x</code>	an object of class "noquote".
<code>quote, ...</code>	further options passed to next methods, such as <code>print</code> .
<code>recursive</code>	for compatibility with the generic <code>c</code> function.

Details

`noquote` returns its argument as an object of class "noquote". There is a method for `c()` and subscript method (`"[.noquote"`) which ensures that the class is not lost by subsetting. The print method (`print.noquote`) prints character strings *without* quotes ("`....`" is printed as `....`).

If `right` is specified in a call `print(x, right=*)`, it takes precedence over a possible `right` setting of `x`, e.g., created by `x <- noquote(*, right=TRUE)`.

These functions exist both as utilities and as an example of using (S3) `class` and object orientation.

nql <- noquote(letters)
nql
nql[1:4] <- "oh"
nql[1:12]

cmp.logical <- function(log.v)
{
  ## Purpose: compact printing of logicals
  log.v <- as.logical(log.v)
  noquote(if(length(log.v) == 0) "()" else c(".", "|")[1 + log.v])
}
cmp.logical(stats::runif(20) > 0.8)

chmat <- as.matrix(format(stackloss)) # a "typical" character matrix
## noquote(*, right=TRUE) so it prints exactly like a data frame
chmat <- noquote(chmat, right = TRUE)
chmat
```

norm

Compute the Norm of a Matrix

Description

Computes a matrix norm of `x` using LAPACK. The norm can be the one ("O") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the "spectral" or "2"-norm, as determined by the value of `type`.

Usage

```
norm(x, type = c("O", "I", "F", "M", "2"))
```

Arguments

<code>x</code>	numeric matrix; note that packages such as Matrix define more <code>norm()</code> methods.
<code>type</code>	character string, specifying the <i>type</i> of matrix norm to be computed. A character indicating the type of norm desired. "O", "o" or "1" specifies the one norm, (maximum absolute column sum); "I" or "i" specifies the infinity norm (maximum absolute row sum); "F", "f", "E" or "e" specifies the Frobenius norm (the Euclidean norm of <code>x</code> treated as if it were a vector);

"M" or "m" specifies the maximum modulus of all the elements in x ; and "2" specifies the “spectral” or 2-norm, which is the largest singular value ([svd](#)) of x .

The default is "O". Only the first character of `type[1]` is used.

Details

The **base** method of `norm()` calls the LAPACK function `dlange`.

Note that the 1-, Inf- and "M" norm is faster to calculate than the Frobenius one.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The matrix norm, a non-negative number. Zero for a 0-extent (empty) matrix.

Source

Except for `norm = "2"`, the LAPACK routine `DLANGE`.

LAPACK is from <https://netlib.org/lapack/>.

See Also

[rcond](#) for the (reciprocal) condition number.

Examples

```
(x1 <- cbind(1, 1:10))
norm(x1)
norm(x1, "I")
norm(x1, "M")
stopifnot(all.equal(norm(x1, "F"),
                     sqrt(sum(x1^2))))

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, `+`) }
h9 <- hilbert(9)
## all 5 (4 different) types of norm:
(nTyp <- eval(formals(base::norm)$type))
sapply(nTyp, norm, x = h9)
stopifnot(exprs = { # 0-extent matrices:
  sapply(nTyp, norm, x = matrix(, 1,0)) == 0
  sapply(nTyp, norm, x = matrix(, 0,0)) == 0
})
```

normalizePath

*Express File Paths in Canonical Form***Description**

Convert file paths to canonical form for the platform, to display them in a user-understandable form and so that relative and absolute paths can be compared.

Usage

```
normalizePath(path, winslash = "\\ ", mustWork = NA)
```

Arguments

path	character vector of file paths.
winslash	the separator to be used on Windows – ignored elsewhere. Must be one of <code>c("/", "\\ ")</code> .
mustWork	logical: if TRUE then an error is given if the result cannot be determined; if NA then a warning.

Details

Tilde-expansion (see [path.expand](#)) is first done on paths.

Where the Unix-alike platform supports it attempts to turn paths into absolute paths in their canonical form (no `'./'`, `'../'` nor symbolic links). It relies on the POSIX system function `realpath`: if the platform does not have that (we know of no current example) then the result will be an absolute path but might not be canonical. Even where `realpath` is used the canonical path need not be unique, for example *via* hard links or multiple mounts.

On Windows it converts relative paths to absolute paths, resolves symbolic links, converts short names for path elements to long names and ensures the separator is that specified by `winslash`. It will match each path element case-insensitively or case-sensitively as during the usual name lookup and return the canonical case. It relies on Windows API function `GetFinalPathNameByHandle` and in case of an error (such as insufficient permissions) it currently falls back to the R 3.6 (and older) implementation, which relies on `GetFullPathName` and `GetLongPathName` with limitations described in the Notes section. An attempt is made not to introduce UNC paths in presence of mapped drives or symbolic links: if `GetFinalPathNameByHandle` returns a UNC path, but `GetLongPathName` returns a path starting with a drive letter, R falls back to the R 3.6 (and older) implementation. UTF-8-encoded paths not valid in the current locale can be used.

`mustWork = FALSE` is useful for expressing paths for use in messages.

Value

A character vector.

If an input is not a real path the result is system-dependent (unless `mustWork = TRUE`, when this should be an error). It will be either the corresponding input element or a transformation of it into an absolute path.

Converting to an absolute file path can fail for a large number of reasons. The most common are

- One of more components of the file path does not exist.

- A component before the last is not a directory, or there is insufficient permission to read the directory.
- For a relative path, the current directory cannot be determined.
- A symbolic link points to a non-existent place or links form a loop.
- The canonicalized path would be exceed the maximum supported length of a file path.

Note

The canonical form of paths may not be what you expect. For example, on macOS absolute paths such as `‘/tmp’` and `‘/var’` are symbolic links. On Linux, a path produced by bash process substitution is a symbolic link (such as `‘/proc/fd/63’`) to a pipe and there is no canonical form of such path. In R 3.6 and older on Windows, symlinks will not be resolved and the long names for path elements will be returned with the case in which they are in `path`, which may not be canonical in case-insensitive folders.

Examples

```
cat(normalizePath(c(R.home(), tempdir())), sep = "\n")
```

NotYet

Not Yet Implemented Functions and Unused Arguments

Description

In order to pinpoint missing functionality, the R core team uses these functions for missing R functions and not yet used arguments of existing R functions (which are typically there for compatibility purposes).

You are very welcome to contribute your code ...

Usage

```
.NotYetImplemented()
.NotYetUsed(arg, error = TRUE)
```

Arguments

<code>arg</code>	an argument of a function that is not yet used.
<code>error</code>	a logical. If <code>TRUE</code> , an error is signalled; if <code>FALSE</code> , only a warning is given.

See Also

the contrary, [Deprecated](#) and [Defunct](#) for outdated code.

Examples

```
require(graphics)
barplot(1:5, inside = TRUE) # 'inside' is not yet used
```

nrow

*The Number of Rows/Columns of an Array***Description**

`nrow` and `ncol` return the number of rows or columns present in `x`. `NCOL` and `NROW` do the same treating a vector as 1-column matrix, even a 0-length vector, compatibly with `as.matrix()` or `cbind()`, see the example.

Usage

```
nrow(x)
ncol(x)
NCOL(x)
NROW(x)
```

Arguments

`x` a vector, array, data frame, or `NULL`.

Value

an `integer` of length 1 or `NULL`, the latter only for `ncol` and `nrow`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X. (`ncol` and `nrow`.)

See Also

`dim` which returns *all* dimensions, and `length` which gives a number (a ‘count’) also in cases where `dim()` is `NULL`, and hence `nrow()` and `ncol()` return `NULL`; `array`, `matrix`.

Examples

```
ma <- matrix(1:12, 3, 4)
nrow(ma)    # 3
ncol(ma)    # 4

ncol(array(1:24, dim = 2:4)) # 3, the second dimension
NCOL(1:12)  # 1
NROW(1:12)  # 12, the length() of the vector

## as.matrix() produces 1-column matrices from 0-length vectors,
## and so does cbind() :
dim(as.matrix(numeric())) # 0 1
dim(  cbind(numeric())) # ditto
NCOL(numeric()) # 1
## However, as.matrix(NULL) fails and cbind(NULL) gives NULL, hence for
## consistency:
NCOL(NULL)    # 0
## (This gave 1 in R < 4.4.0.)
```

ns-dblcolon*Double Colon and Triple Colon Operators*

Description

Accessing exported and internal variables, i.e. R objects (including lazy loaded data sets) in a namespace.

Usage

```
pkg::name  
pkg:::name
```

Arguments

pkg	package name: symbol or literal character string.
name	variable name: symbol or literal character string.

Details

For a package **pkg**, `pkg::name` returns the value of the exported variable `name` in namespace `pkg`, whereas `pkg:::name` returns the value of the internal variable `name`. The package namespace will be loaded if it was not loaded before the call, but the package will not be attached to the search path.

Specifying a variable or package that does not exist is an error.

Note that `pkg::name` does **not** access the objects in the environment `package:pkg` (which does not exist until the package's namespace is attached): the latter may contain objects not exported from the namespace. It can access datasets made available by lazy-loading.

Note

It is typically a design mistake to use `:::` in your code since the corresponding object has probably been kept internal for a good reason. Consider contacting the package [maintainer](#) if you feel the need to access the object for anything but mere inspection.

See Also

[get](#) to access an object masked by another of the same name. [loadNamespace](#), [asNamespace](#) for more about namespaces.

Examples

```
base::log  
base::"+"  
  
## Beware -- use ':::' at your own risk! (see "Details")  
stats:::coef.default
```

Description

Packages can supply functions to be called when loaded, attached, detached or unloaded.

Usage

```
.onLoad(libname, pkgname)
.onAttach(libname, pkgname)
.onUnload(libpath)
.onDetach(libpath)
.Last.lib(libpath)
```

Arguments

libname	a character string giving the library directory where the package defining the namespace was found.
pkgname	a character string giving the name of the package.
libpath	a character string giving the complete path to the package.

Details

After loading, `loadNamespace` looks for a hook function named `.onLoad` and calls it (with two unnamed arguments) before sealing the namespace and processing exports.

When the package is attached (via `library` or `attachNamespace`), the hook function `.onAttach` is looked for and if found is called (with two unnamed arguments) before the package environment is sealed.

If a function `.onDetach` is in the namespace or `.Last.lib` is exported from the package, it will be called (with a single argument) when the package is `detached`. Beware that it might be called if `.onAttach` has failed, so it should be written defensively. (It is called within `tryCatch`, so errors will not stop the package being detached.)

If a namespace is unloaded (via `unloadNamespace`), a hook function `.onUnload` is run (with a single argument) before final unloading.

Note that the code in `.onLoad` and `.onUnload` should not assume any package except the base package is on the search path. Objects in the current package will be visible (unless this is circumvented), but objects from other packages should be imported or the double colon operator should be used.

`.onLoad`, `.onUnload`, `.onAttach` and `.onDetach` are looked for as internal objects in the namespace and should not be exported (whereas `.Last.lib` should be).

Note that packages are not detached nor namespaces unloaded at the end of an R session unless the user arranges to do so (e.g., via `.Last`).

Anything needed for the functioning of the namespace should be handled at load/unload times by the `.onLoad` and `.onUnload` hooks. For example, DLLs can be loaded (unless done by a `useDynLib` directive in the 'NAMESPACE' file) and initialized in `.onLoad` and unloaded in `.onUnload`. Use `.onAttach` only for actions that are needed only when the package becomes visible to the user (for example a start-up message) or need to be run after the package environment has been created.

Good practice

Loading a namespace should where possible be silent, with startup messages given by `.onAttach`. These messages (and any essential ones from `.onLoad`) should use `packageStartupMessage` so they can be silenced where they would be a distraction.

There should be no calls to `library` nor `require` in these hooks. The way for a package to load other packages is via the ‘Depends’ field in the ‘DESCRIPTION’ file: this ensures that the dependence is documented and packages are loaded in the correct order. Loading a namespace should not change the search path, so rather than attach a package, dependence of a namespace on another package should be achieved by (selectively) importing from the other package’s namespace.

Uses of `library` with argument `help` to display basic information about the package should use `format` on the computed package information object and pass this to `packageStartupMessage`.

There should be no calls to `installed.packages` in startup code: it is potentially very slow and may fail in versions of R before 2.14.2 if package installation is going on in parallel. See its help page for alternatives.

Compiled code should be loaded (e.g., via `library.dynam`) in `.onLoad` or a `useDynLib` directive in the ‘NAMESPACE’ file, and not in `.onAttach`. Similarly, compiled code should not be unloaded (e.g., via `library.dynam.unload`) in `.Last.lib` nor `.onDetach`, only in `.onUnload`.

See Also

`setHook` shows how users can set hooks on the same events, and lists the sequence of events involving all of the hooks.

`reg.finalizer` for hooks to be run at the end of a session.

`loadNamespace` for more about namespaces.

 ns-load

Loading and Unloading Name Spaces

Description

Functions to load and unload name spaces explicitly. Loading namespaces typically happens automatically, often from `library()` or also when other packages import their dependent package namespaces.

Usage

```
attachNamespace(ns, pos = 2L, depends = NULL, exclude, include.only)
loadNamespace(package, lib.loc = NULL,
               keep.source = getOption("keep.source.pkgs"),
               partial = FALSE, versionCheck = NULL,
               keep.parse.data = getOption("keep.parse.data.pkgs"))
requireNamespace(package, ..., quietly = FALSE)
loadedNamespaces()
unloadNamespace(ns)
isNamespaceLoaded(name)
```

Arguments

<code>ns</code>	string or name space object.
<code>pos</code>	integer specifying position to attach.
<code>depends</code>	NULL or a character vector of dependencies to be recorded in object <code>.</code> . Depends in the package.
<code>package</code>	string naming the package/name space to load.
<code>lib.loc</code>	character vector specifying library search path (the location of R library trees to search through. Only used if the name space is not already loaded.
<code>keep.source</code>	now ignored except during package installation.
<code>keep.parse.data</code>	ignored except during package installation.
<code>partial</code>	logical; if true, stop just after loading code.
<code>versionCheck</code>	NULL or a version specification, i.e., a list with components <code>op</code> and <code>version</code> where <code>op</code> is a string denoting a Comparison operator such as <code>">="</code> , <code>"=="</code> , <code>"<"</code> , etc.
<code>quietly</code>	logical: should progress and error messages be suppressed?
<code>name</code>	string or 'name', see as.symbol , of a package, e.g., <code>"stats"</code> .
<code>exclude, include.only</code>	character vectors; see library .
<code>...</code>	further arguments to be passed to <code>loadNamespace</code> .

Details

The functions `loadNamespace` and `attachNamespace` are usually called implicitly when [library](#) is used to load a name space and any imports needed. However it may be useful at times to call these functions directly.

`loadNamespace` loads the specified name space and registers it in an internal data base. A request to load a name space when one of that name is already loaded has no effect and all other arguments except `versionCheck` are ignored. In R <= 4.5.z, an invalid version specification, e.g., `versionCheck = "0.3.0"` would often pass unnoticed and be misinterpreted as non-availability of the package; now an error is signalled.

Argument `versionCheck` allows to require a namespace with restricted (e.g., minimal or maximal) package version ([packageVersion\(\)](#)). If the version check fails, `loadNamespace()` signals an error, whereas `requireNamespace()` returns `FALSE` after showing `loadNamespace`'s error message.

Further arguments have the same meaning as the corresponding arguments to [library](#), whose help page explains the details of how a particular installed package comes to be chosen. After loading, `loadNamespace` looks for a hook function named `.onLoad` as an internal variable in the name space (it should not be exported). Partial loading is used to support installation with lazy-loading.

Optionally the package licence is checked during loading: see section 'Licenses' in the help for [library](#).

`loadNamespace` does not attach the name space it loads to the search path. `attachNamespace` can be used to attach a frame containing the exported values of a name space to the search path (but this is almost always done *via* [library](#)). The hook function `.onAttach` is run after the name space exports are attached.

`requireNamespace` is a wrapper for `loadNamespace` analogous to `require` that returns a logical value.

`loadedNamespaces` returns a character vector of the names of the loaded name spaces.

`isNamespaceLoaded(pkg)` is equivalent to but more efficient than `pkg %in% loadedNamespaces()`.

`unloadNamespace` can be used to attempt to force a name space to be unloaded. If the name space is attached, it is first `detached`, thereby running a `.onDetach` or `.Last.lib` function in the name space if one is exported. An error is signaled and the name space is not unloaded if the name space is imported by other loaded name spaces. If defined, a hook function `.onUnload` is run before removing the name space from the internal registry.

See the comments in the help for `detach` about some issues with unloading and reloading name spaces.

Value

`attachNamespace` returns invisibly the package environment it adds to the search path.

`loadNamespace` returns the name space environment, either one already loaded or the one the function causes to be loaded.

`requireNamespace` returns TRUE if it succeeds or FALSE.

`loadedNamespaces` returns a `character` vector.

`unloadNamespace` returns NULL, invisibly.

Tracing

As from R 4.1.0 the operation of `loadNamespace` can be traced, which can help track down the causes of unexpected messages (including which package(s) they come from since `loadNamespace` is called in many ways including from itself and by `::` and can be called by `load`). Setting the environment variable `_R_TRACE_LOADNAMESPACE_` to a numerical value will generate additional messages on progress. Non-zero values, e.g. 1, report which namespace is being loaded and when loading completes; values 2 to 4 report in increasing detail. Negative values are reserved for tracing specific features and their current meanings are documented in source-code comments.

Loading standard packages is never traced.

Author(s)

Luke Tierney and R-core

References

Section “**Package namespaces**” in *Writing R Extensions*.

See Also

`getNamespace`, `asNamespace`, `topenv`, `.onLoad` (etc); further `environment`.

Examples

```
(lns <- loadedNamespaces())
statL <- isNamespaceLoaded("stats")
stopifnot( identical(statL, "stats" %in% lns) )

## The string "foo" and the symbol 'foo' can be used interchangeably here:
stopifnot( identical(isNamespaceLoaded( "foo" ), FALSE),
           identical(isNamespaceLoaded(quote(foo)), FALSE),
           identical(isNamespaceLoaded(quote(stats)), statL))

hasS <- isNamespaceLoaded("splines") # (to restore if needed)
Sns <- asNamespace("splines") # loads it if not already
stopifnot( isNamespaceLoaded("splines"))
if (is.null(try(unloadNamespace(Sns)))) # try unloading the NS 'object'
stopifnot( ! isNamespaceLoaded("splines"))
if (hasS) loadNamespace("splines") # (restoring previous state)
```

ns-topenv

Top Level Environment

Description

Finding the top level [environment](#) from an environment `envir` and its enclosing environments.

Usage

```
topenv(envir = parent.frame(),
       matchThisEnv = getOption("topLevelEnvironment"))
```

Arguments

`envir` environment.

`matchThisEnv` return this environment, if it matches before any other criterion is satisfied. The default, the option ‘`topLevelEnvironment`’, is set by [sys.source](#), which treats a specific environment as the top level environment. Supplying the argument as `NULL` or `emptyenv()` means it will never match.

Details

`topenv` returns the first top level [environment](#) found when searching `envir` and its enclosing environments. If no top level environment is found, `.GlobalEnv` is returned. An environment is considered top level if it is the internal environment of a namespace, a package environment in the [search](#) path, or `.GlobalEnv`.

See Also

[environment](#), notably `parent.env()` on “enclosing environments”; [loadNamespace](#) for more on namespaces.

Examples

```
topenv(.GlobalEnv)
topenv(new.env()) # also global env
topenv(environment(ls)) # namespace:base
topenv(environment(lm)) # namespace:stats
```

NULL

The Null Object

Description

NULL represents the null object in R: it is a [reserved](#) word. NULL is often returned by expressions and functions whose value is undefined.

Usage

```
NULL
as.null(x, ...)
is.null(x)
```

Arguments

<code>x</code>	an object to be tested or coerced.
<code>...</code>	ignored.

Details

NULL can be indexed (see [Extract](#)) in just about any syntactically legal way: apart from `NULL[[]]` which is an error, the result is always NULL. Objects with value NULL can be changed by replacement operators and will be coerced to the type of the right-hand side.

NULL is also used as the empty [pairlist](#): see the examples. Because pairlists are often promoted to lists, you may encounter NULL being promoted to an empty list.

Objects with value NULL cannot have attributes as there is only one null object: attempts to assign them are either an error ([attr](#)) or promote the object to an empty list with attribute(s) ([attributes](#) and [structure](#)).

Value

`as.null` ignores its argument and returns NULL.

`is.null` returns TRUE if its argument's value is NULL and FALSE otherwise.

Note

`is.null` is a [primitive](#) function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`%||%: L %||% R` is equivalent to `if(!is.null(L)) L else R`

Examples

```
is.null(list())      # FALSE (on purpose!)
is.null(pairlist()) # TRUE
is.null(integer(0)) # FALSE
is.null(logical(0)) # FALSE
as.null(list(a = 1, b = "c"))
```

 numeric

Numeric Vectors

Description

Creates or coerces objects of type "numeric". `is.numeric` is a more general test of an object being interpretable as numbers.

Usage

```
numeric(length = 0)
as.numeric(x, ...)
is.numeric(x)
```

Arguments

<code>length</code>	a non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
<code>x</code>	object to be coerced or tested.
<code>...</code>	further arguments passed to or from other methods.

Details

`numeric` is identical to `double`. It creates a double-precision vector of the specified length with each element equal to 0.

`as.numeric` is a generic function, but S3 methods must be written for `as.double`. It is identical to `as.double`.

`is.numeric` is an [internal generic](#) primitive function: you can write methods to handle specific classes of objects, see [InternalMethods](#). It is **not** the same as `is.double`. Factors are handled by the default method, and there are methods for classes "`complex`", "`Date`", "`POSIXt`" and "`difftime`" (all of which return false). Methods for `is.numeric` should only return true if the base type of the class is `double` or `integer` *and* values can reasonably be regarded as numeric (e.g., arithmetic on them makes sense, and comparison should be done via the base type).

Value

for `numeric` and `as.numeric` see `double`.

The default method for `is.numeric` returns TRUE if its argument is of [mode](#) "numeric" ([type](#) "double" or [type](#) "integer") and not a factor, and FALSE otherwise. That is, `is.integer(x) || is.double(x)`, or `(mode(x) == "numeric") && !is.factor(x)`.

Warning

If `x` is a `factor`, `as.numeric` will return the underlying numeric (integer) representation, which is often meaningless as it may not correspond to the `factor levels`, see the ‘Warning’ section in `factor` (and the 2nd example below).

S4 methods

`as.numeric` and `is.numeric` are internally S4 generic and so methods can be set for them *via* `setMethod`.

To ensure that `as.numeric` and `as.double` remain identical, S4 methods can only be set for `as.numeric`.

Note on names

It is a historical anomaly that **R** has two names for its floating-point vectors, `double` and `numeric` (and formerly had `real`).

`double` is the name of the `type`. `numeric` is the name of the `mode` and also of the implicit `class`. As an S4 formal class, use `"numeric"`.

The potential confusion is that **R** has used `mode "numeric"` to mean ‘double or integer’, which conflicts with the S4 usage. Thus `is.numeric` tests the mode, not the class, but `as.numeric` (which is identical to `as.double`) coerces to the class.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`double`, `integer`, `storage.mode`.

Examples

```
## Conversion does trim whitespace; non-numeric strings give NA + warning
as.numeric(c("-.1", " 2.7 ", "B"))

## Numeric values are sometimes accidentally converted to factors.
## Converting them back to numeric is trickier than you'd expect.
f <- factor(5:10)
as.numeric(f) # not what you might expect, probably not what you want
## what you typically meant and want:
as.numeric(as.character(f))
## the same, considerably more efficient (for long vectors):
as.numeric(levels(f))[f]
```

Description

How R parses numeric constants.

Details

R parses numeric constants in its input in a very similar way to C99 floating-point constants.

`Inf` and `NaN` are numeric constants (with `typeof(.)` "double"). In text input (e.g., in `scan` and `as.double`), these are recognized ignoring case as is `infinity` as an alternative to `Inf`. `NA_real_` and `NA_integer_` are constants of types "double" and "integer" representing missing values. All other numeric constants start with a digit or period and are either a decimal or hexadecimal constant optionally followed by `L`.

Hexadecimal constants start with `0x` or `0X` followed by a non-empty sequence from 0–9 a–f A–F . which is interpreted as a hexadecimal number, optionally followed by a binary exponent. A binary exponent consists of a `P` or `p` followed by an optional plus or minus sign followed by a non-empty sequence of (decimal) digits, and indicates multiplication by a power of two. Thus `0x123p456` is 291×2^{456} .

Decimal constants consist of a non-empty sequence of digits possibly containing a period (the decimal point), optionally followed by a decimal exponent. A decimal exponent consists of an `E` or `e` followed by an optional plus or minus sign followed by a non-empty sequence of digits, and indicates multiplication by a power of ten.

Values which are too large or too small to be representable will overflow to `Inf` or underflow to `0.0`.

A numeric constant immediately followed by `i` is regarded as an imaginary [complex](#) number.

A numeric constant immediately followed by `L` is regarded as an [integer](#) number when possible (and with a warning if it contains a ".").

Only the ASCII digits 0–9 are recognized as digits, even in languages which have other representations of digits. The ‘decimal separator’ is always a period and never a comma.

Note that a leading plus or minus is not regarded by the parser as part of a numeric constant but as a unary operator applied to the constant.

Note

When a string is parsed to input a numeric constant, the number may or may not be representable exactly in the C double type used. If not one of the nearest representable numbers will be returned.

R’s own C code is used to convert constants to binary numbers, so the effect can be expected to be the same on all platforms implementing full IEC 60559 arithmetic (the most likely area of difference being the handling of numbers less than `.Machine$double.xmin`). The same code is used by `scan`.

See Also

[Syntax](#). For complex numbers, see [complex](#). [Quotes](#) for the parsing of character constants, [Reserved](#) for the “reserved words” in R.

Examples

```
## You can create numbers using fixed or scientific formatting.
2.1
2.1e10
-2.1E-10

## The resulting objects have class numeric and type double.
class(2.1)
typeof(2.1)

## This holds even if what you typed looked like an integer.
class(2)
typeof(2)

## If you actually wanted integers, use an "L" suffix.
class(2L)
typeof(2L)

## These are equal but not identical
2 == 2L
identical(2, 2L)

## You can write numbers between 0 and 1 without a leading "0"
## (but typically this makes code harder to read)
.1234

sqrt(1i) # remember elementary math?
utils::str(0xA0)
identical(1L, as.integer(1))

## You can combine the "0x" prefix with the "L" suffix :
identical(0xFL, as.integer(15))
```

numeric_version	<i>Numeric Versions</i>
-----------------	-------------------------

Description

A simple S3 class for representing numeric versions including package versions, and associated methods.

Usage

```
numeric_version(x, strict = TRUE)
package_version(x, strict = TRUE)
R_system_version(x, strict = TRUE)
getRversion()
as.numeric_version(x)
as.package_version(x)
is.numeric_version(x)
is.package_version(x)
```

Arguments

<code>x</code>	for the creators, a character vector with suitable numeric version strings (see ‘Details’); for <code>package_version</code> , alternatively an R version object as obtained by <code>R.version</code> . For <code>as.numeric_version</code> and <code>as.package_version</code> , suitable character vectors as above, or numeric version objects. For <code>is.numeric_version</code> and <code>is.package_version</code> , arbitrary R objects.
<code>strict</code>	a logical indicating whether invalid numeric versions should result in an error (default) or not.

Details

Numeric versions are sequences of one or more non-negative integers, usually (e.g., in package ‘DESCRIPTION’ files) represented as character strings with the elements of the sequence concatenated and separated by single ‘.’ or ‘-’ characters. R package versions consist of at least two such integers, an R system version of exactly three (major, minor and patch level).

Functions `numeric_version`, `package_version` and `R_system_version` create a representation from such strings (if suitable) which allows for coercion and testing, combination, comparison, summaries (min/max), inclusion in data frames, subscripting, and printing. The classes can hold a vector of such representations.

`getRversion` returns the version of the running R as an R system version object.

The `[]` operator extracts or replaces a single version. To access the integers of a version use two indices: see the examples.

See Also

`compareVersion`; `packageVersion` for the version of a specific R package. `R.version` etc for the version of R (and the information underlying `getRversion()`).

Examples

```
x <- package_version(c("1.2-4", "1.2-3", "2.1"))
x < "1.4-2.3"
c(min(x), max(x))
x[2, 2]
x$major
x$minor

if(getRversion() <= "2.5.0") { ## work around missing feature
  cat("Your version of R, ", as.character(getRversion()),
      ", is outdated.\n",
      "Now trying to work around that ...\n", sep = "")
}

x[[1]]
x[[c(1, 3)]] # '4' as a numeric version
x[1, 3]      # same
x[[1, 3]]    # 4 as an integer

x[[2, 3]] <- 0 # zero the patchlevel
x[[c(2, 3)]] <- 0 # same
x
```

```
x[[3]] <- "2.2.3"
x

x <- c(x, package_version("0.0"))
is.na(x)[4] <- TRUE
stopifnot(identical(is.na(x), c(rep(FALSE, 3), TRUE)),
  anyNA(x))
```

octmode

Integer Numbers Displayed in Octal

Description

Integers which are displayed in octal (base-8 number system) format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Arithmetic works as for integers, and non-integer valued mathematical functions typically work by truncating the result to integer.

Usage

```
as.octmode(x)

## S3 method for class 'octmode'
as.character(x, keepStr = FALSE, ...)

## S3 method for class 'octmode'
format(x, width = NULL, ...)

## S3 method for class 'octmode'
print(x, ...)
```

Arguments

<code>x</code>	an object, for the methods inheriting from class "octmode".
<code>keepStr</code>	a logical indicating that names and dimensions should be kept; set TRUE for back compatibility, if needed.
<code>width</code>	NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.
<code>...</code>	further arguments passed to or from other methods.

Details

"octmode" objects are integer vectors with that class attribute, used primarily to ensure that they are printed in octal notation, specifically for Unix-like file permissions such as 755. Subsetting ([\[\]](#)) works too, as do arithmetic or other mathematical operations, albeit truncated to integer.

`as.character(x)` drops all [attributes](#) (unless when `keepStr=TRUE` where it keeps, `dim`, `dimnames` and `names` for back compatibility) and converts each entry individually, hence with no leading zeroes, whereas in `format()`, when `width = NULL` (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

`as.octmode` can convert integers (of `type` "integer" or "double") and character vectors whose elements contain only digits 0–7 (or are NA) to class "octmode".

There is a `!` method and methods for `|` and `&`: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

See Also

These are auxiliary functions for `file.info`.

`hexmode`, `sprintf` for other options in converting integers to octal, `strtoi` to convert octal strings to integers.

Examples

```
(on <- as.octmode(c(16, 32, 127:129))) # "020" "040" "177" "200" "201"
unclass(on[3:4]) # subsetting

## manipulate file modes
fmode <- as.octmode("170")
(fmode | "644") & "755"

(umask <- Sys.umask()) # depends on platform
c(fmode, "666", "755") & !umask

om <- as.octmode(1:12)
om # print()s via format()
stopifnot(nchar(format(om)) == 2)
om[1:7] # *no* leading zeroes!
stopifnot(format(om[1:7]) == as.character(1:7))
om2 <- as.octmode(c(1:10, 60:70))
om2 # prints via format() -> with 3 octals
stopifnot(nchar(format(om2)) == 3)
as.character(om2) # strings of length 1, 2, 3

## Integer arithmetic (remaining "octmode"):
om^2
om * 64
-om
(fac <- factorial(om)) # !1, !2, !3, !4 .. in hexadecimals
as.integer(fac) # indeed the same as factorial(1:12)
```

on.exit

Function Exit Code

Description

`on.exit` records the expression given as its argument as needing to be executed when the current function exits (either naturally or as the result of an error). This is useful for resetting graphical parameters or performing other cleanup actions.

If no expression is provided, i.e., the call is `on.exit()`, then the current `on.exit` code is removed.

Usage

```
on.exit(expr = NULL, add = FALSE, after = TRUE)
```

Arguments

<code>expr</code>	an expression to be executed.
<code>add</code>	if TRUE, add <code>expr</code> to be executed after any previously set expressions (or before if <code>after</code> is FALSE); otherwise (the default) <code>expr</code> will overwrite any previously set expressions.
<code>after</code>	if <code>add</code> is TRUE and <code>after</code> is FALSE, then <code>expr</code> will be added on top of the expressions that were already registered. The resulting last in first out order is useful for freeing or closing resources in reverse order.

Details

The `expr` argument passed to `on.exit` is recorded without evaluation. If it is not subsequently removed/replaced by another `on.exit` call in the same function, it is evaluated in the evaluation frame of the function when it exits (including during standard error handling). Thus any functions or variables in the expression will be looked for in the function and its environment at the time of exit: to capture the current value in `expr` use `substitute` or similar.

If multiple `on.exit` expressions are set using `add = TRUE` then all expressions will be run even if one signals an error.

This is a ‘special’ [primitive](#) function: it only evaluates the arguments `add` and `after`.

Value

Invisible NULL.

See Also

[sys.on.exit](#) which returns the expression stored for use by `on.exit()` in the function in which `sys.on.exit()` is evaluated.

Examples

```
require(graphics)

opar <- par(mai = c(1,1,1,1))
on.exit(par(opar))
```

Ops.Date

*Operators on the Date Class***Description**

Operators for the "Date" class.

There is an `Ops` method and specific methods for `+` and `-` for the `Date` class.

Usage

```
date + x
x + date
date - x
date1 lop date2
```

Arguments

<code>date</code>	an object of class "Date".
<code>date1, date2</code>	date objects or character vectors. (Character vectors are converted by <code>as.Date</code> .)
<code>x</code>	a numeric vector (in days) or an object of class "difftime", rounded to the nearest whole day.
<code>lop</code>	one of <code>==</code> , <code>!=</code> , <code><</code> , <code><=</code> , <code>></code> or <code>>=</code> .

Details

`x` does not need to be integer if specified as a numeric vector, but see the comments about fractional days in the help for `Dates`.

Examples

```
(z <- Sys.Date())
z + 10
z < c("2009-06-01", "2010-01-01", "2015-01-01")
```

options

*Options Settings***Description**

Allow the user to set and examine a variety of global *options* which affect the way in which R computes and displays its results.

Usage

```
options(...)

getOption(x, default = NULL)

.Options
```

Arguments

...	any options can be defined, using <code>name = value</code> . However, only the ones below are used in base R. Options can also be passed by giving a single unnamed argument which is a named list.
x	a character string holding an option name.
default	if the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.

Details

Invoking `options()` with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one should use, e.g., `getOption("width")` rather than `options("width")` which is a *list* of length one.

Value

For `getOption`, the current value set for option `x`, or `default` (which defaults to `NULL`) if the option is unset.

For `options()`, a list of all set options sorted by name. For `options(name)`, a list of length one containing the set value, or `NULL` if it is unset. For uses setting one or more options, a list with the previous values of the options changed (returned invisibly).

Options used in base R

`add.smooth`: typically logical, defaulting to `TRUE`. Could also be set to an integer for specifying how many (simulated) smooths should be added. This is currently only used by `plot.lm`.

`askYesNo`: a function (typically set by a front-end) to ask the user binary response functions in a consistent way, or a vector of strings used by `askYesNo` to use as default responses for such questions.

`browserNLdisabled`: logical: whether newline is disabled as a synonym for "n" in the browser.

`catch.script.errors`: logical, false by default. If true *and* `interactive()` is false, e.g., when an R script is run by R CMD BATCH `<script>.R`, then errors do *not* stop execution of the script. Rather evaluation continues after printing the error (and jumping to top level). Also, `traceback()` would provide info about the error. Do use with care!

`checkPackageLicense`: logical, not set by default. If true, `loadNamespace` asks a user to accept any non-standard license at first load of the package.

`check.bounds`: logical, defaulting to `FALSE`. If true, a **warning** is produced whenever a vector (atomic or `list`) is extended, by something like `x <- 1:3; x[5] <- 6`.

`CBoundsCheck`: logical, controlling whether `.C` and `.Fortran` make copies to check for array over-runs on the atomic vector arguments.

Initially set from value of the environment variable `R_C_BOUNDS_CHECK` (set to `yes` to enable).

`conflicts.policy`: character string or list controlling handling of conflicts found in calls to `library` or `require`. See `library` for details.

`continue`: a non-empty string setting the prompt used for lines which continue over one line.

defaultPackages: the packages that are attached by default when R starts up. Initially set from the value of the environment variable `R_DEFAULT_PACKAGES`, or if that is unset to `c("datasets", "utils", "grDevices", "graphics", "stats", "methods")`. (Set `R_DEFAULT_PACKAGES` to `NULL` or a comma-separated list of package names.) This option can be changed in a `‘.Rprofile’` file, but it will not work to exclude the **methods** package at this stage, as the value is screened for **methods** before that file is read.

deparse.cutoff: integer value controlling the printing of language constructs which are [deparsed](#). Default 60.

deparse.max.lines: controls the number of lines used when deparsing in [browser](#), upon entry to a function whose debugging flag is set, and if option `traceback.max.lines` is unset, of `traceback()`. Initially unset, and only used if set to a positive integer.

traceback.max.lines: controls the number of lines used when deparsing in [traceback](#), if set. Initially unset, and only used if set to a positive integer.

digits: controls the number of *significant* (see [signif](#)) digits to print when printing numeric values. It is a suggestion only. Valid values are 1...22 with default 7. See the note in [print.default](#) about values greater than 15.

digits.secs: controls the maximum number of digits to print when formatting time values in seconds. Valid values are 0...6 with default 0 (equivalent to `NULL` which is used when it is undefined as on vanilla startup). See [strftime](#).

download.file.extra: Extra command-line argument(s) for non-default methods: see [download.file](#).

download.file.method: Method to be used for `download.file`. Currently download methods "internal", "wininet" (Windows only), "libcurl", "wget" and "curl" are available. If not set, `method = "auto"` is chosen: see [download.file](#).

echo: logical. Only used in non-interactive mode, when it controls whether input is echoed. Command-line option `‘--no-echo’` sets this to `FALSE`, but otherwise it starts the session as `TRUE`.

encoding: The name of an encoding, default `"native.enc"`. See [connections](#).

error: either a function or an expression governing the handling of non-catastrophic errors such as those generated by [stop](#) as well as by signals and internally detected errors. If the option is a function, a call to that function, with no arguments, is generated as the expression. By default the option is not set: see [stop](#) for the behaviour in that case. The functions [dump.frames](#) and [recover](#) provide alternatives that allow post-mortem debugging. Note that these need to be specified as e.g. `options(error = utils::recover)` in startup files such as `‘.Rprofile’`.

expressions: sets a limit on the number of nested expressions that will be evaluated. Valid values are 25...500000 with default 5000. If you increase it, you may also want to start R with a larger protection stack; see `‘--max-ppsize’` in [Memory](#). Note too that you may cause a segfault from overflow of the C stack, and on OSes where it is possible you may want to increase that. Once the limit is reached an error is thrown. The current number under evaluation can be found by calling [Cstack_info](#).

interrupt: a function taking no arguments to be called on a user interrupt if the interrupt condition is not otherwise handled.

keep.parse.data: When internally storing source code (`keep.source` is `TRUE`), also store parse data. Parse data can then be retrieved with [getParseData\(\)](#) and used e.g. for spell checking of string constants or syntax highlighting. The value has effect only when internally storing source code (see `keep.source`). The default is `TRUE`.

`keep.parse.data.pkgs`: As for `keep.parse.data`, used only when packages are installed. Defaults to `FALSE` unless the environment variable `R_KEEP_PKG_PARSE_DATA` is set to `yes`. The space overhead of parse data can be substantial even after compression and it causes performance overhead when loading packages.

`keep.source`: When `TRUE`, the source code for functions (newly defined or loaded) is stored internally allowing comments to be kept in the right places. Retrieve the source by printing or using `deparse(fn, control = "useSource")`.

The default is `interactive()`, i.e., `TRUE` for interactive use.

`keep.source.pkgs`: As for `keep.source`, used only when packages are installed. Defaults to `FALSE` unless the environment variable `R_KEEP_PKG_SOURCE` is set to `yes`.

`matprod`: a string selecting the implementation of the matrix products `%*%`, `crossprod`, and `tcrossprod` for double and complex vectors:

"internal" uses an unoptimized 3-loop algorithm which correctly propagates `NaN` and `Inf` values and is consistent in precision with other summation algorithms inside R like `sum` or `colSums` (which now means that it uses a long double accumulator for summation if available and enabled, see `capabilities`).

"default" uses BLAS to speed up computation, but to ensure correct propagation of `NaN` and `Inf` values it uses an unoptimized 3-loop algorithm for inputs that may contain `NaN` or `Inf` values. When deemed beneficial for performance, "default" may call the 3-loop algorithm unconditionally, i.e., without checking the input for `NaN/Inf` values. The 3-loop algorithm uses (only) a double accumulator for summation, which is consistent with the reference BLAS implementation.

"blas" uses BLAS unconditionally without any checks and should be used with extreme caution. BLAS libraries do not propagate `NaN` or `Inf` values correctly and for inputs with `NaN/Inf` values the results may be undefined.

"default.simd" is experimental and will likely be removed in future versions of R. It provides the same behavior as "default", but the check whether the input contains `NaN/Inf` values is faster on some SIMD hardware. On older systems it will run correctly, but may be much slower than "default".

`max.print`: integer, defaulting to 99999. `print` or `show` methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) `max.print entries`.

`netrc`: character string. Path to netrc file with user credentials for URLs requiring authentication. The file, if it exists, will be used by 'libcurl' in `download.file`, `url` and `curlGetHeaders`. By default unset, but can be set from environment variable `R_DEFAULT_NETRC`.

`OutDec`: character string containing a single character. The preferred character to be used as the decimal point in output conversions, that is in printing, plotting, `format`, `formatC` and `as.character` but not when deparsing nor by `sprintf` (which is sometimes used prior to printing).

`pager`: the command used for displaying text files by `file.show`, details depending on the platform:

On a unix-alike defaults to '`R_HOME/bin/pager`', which is a shell script running the command-line specified by the environment variable `PAGER` whose default is set at configuration, usually to `less`.

On Windows defaults to "internal", which uses a pager similar to the GUI console. Another possibility is "console" to use the console itself.

Can be a character string or an R function, in which case it needs to accept the arguments (`files`, `header`, `title`, `delete.file`) corresponding to the first four arguments of `file.show`.

papersize: the default paper format used by `postscript`; set by environment variable `R_PAPERSIZE` when `R` is started; if that is unset or invalid it defaults platform dependently

on a unix-alike to a value derived from the locale category `LC_PAPER`, or if that is unavailable to a default set when `R` was built.

on Windows to "a4", or "letter" in US and Canadian locales.

PCRE_limit_recursion: Logical: should `grep` (`perl = TRUE`) and similar limit the maximal recursion allowed when matching? Only relevant for PCRE1 and PCRE2 <= 10.23.

PCRE can be built not to use a recursion stack (see `pcre_config`), but it uses recursion by default with a recursion limit of 10000000 which potentially needs a very large C stack: see the discussion at <https://www.pcre.org/original/doc/html/pcrestack.html>. If true, the limit is reduced using `R`'s estimate of the C stack size available (if known), otherwise 10000. If NA, the limit is imposed only if any input string has 1000 or more bytes. The limit has no effect when PCRE's Just-in-Time compiler is used.

PCRE_study: Logical or integer: should `grep` (`perl = TRUE`) and similar 'study' the patterns? Either logical or a numerical threshold for the minimum number of strings to be matched for the pattern to be studied (the default is 10)). Missing values and negative numbers are treated as false. This option is ignored with PCRE2 (PCRE version >= 10.00) which does not have a separate study phase and patterns are automatically optimized when possible.

PCRE_use_JIT: Logical: should `grep` (`perl = TRUE`), `strsplit` (`perl = TRUE`) and similar make use of PCRE's Just-In-Time compiler if available? (This applies only to studied patterns with PCRE1.) Default: true. Missing values are treated as false.

pdfviewer: default PDF viewer. The default is set from the environment variable `R_PDFVIEWER`, the default value of which

on a unix-alike is set when `R` is configured, and

on Windows is the full path to `open.exe`, a utility supplied with `R`.

printcmd: the command used by `postscript` for printing; set by environment variable `R_PRINTCMD` when `R` is started. This should be a command that expects either input to be piped to 'stdin' or to be given a single filename argument. Usually set to "lpr" on a Unix-alike.

prompt: a non-empty string to be used for `R`'s prompt; should usually end in a blank (" ").

quiet: logical. Should `R` be (more) "quiet", notably on startup report? Set to `TRUE` by the command-line option '--quiet'. Note that `quiet` and `verbose` can both be true.

rl_word_breaks: (Unix only:) Used for the readline-based terminal interface. Default value "`\t\n\"\\'`>=<=; , | & { () }`".

This is the set of characters use to break the input line into tokens for object- and file-name completion. Those who do not use spaces around operators may prefer

"`\t\n\"\\'`>=<=+-* ; , | & { () }`"

save.defaults, save.image.defaults: see `save`.

scipen: integer. A penalty to be applied when deciding to print numeric values in fixed or exponential notation. Positive values bias towards fixed and negative towards scientific notation: fixed notation will be preferred unless it is more than `scipen` digits wider. The default is 0. Valid values are between -9 and 9999 where "relevant" values (for double precision accuracy) are in -6:319. Some invalid values currently signal a `warning` and are set to legal boundaries if finite. These may signal an error in a future version of `R`.

setWidthOnResize: a logical. If set and `TRUE`, `R` run in a terminal using a recent readline library will set the `width` option when the terminal is resized.

- `showWarnCalls`, `showErrorCalls`: a logical. Should warning and error messages produced by the default handlers show a summary of the call stack? By default error call stacks are shown in non-interactive sessions. When `warning` or `stop` are called on a condition object the call stacks are only shown if the value returned by `conditionCall` for the condition object is not `NULL`.
- `showNCalls`: integer. Controls how long the sequence of calls must be (in bytes) before ellipses are used. Defaults to 50 and should be at least 30 and no more than 500.
- `show.error.locations`: Should source locations of errors be printed? If set to `TRUE` or `"top"`, the source location that is highest on the stack (the most recent code with source information) will be printed.
- `show.error.messages`: a logical. Should error messages be printed? Intended for use with `try` or a user-installed error handler.
- `texi2dvi`: used by functions `texi2dvi` and `texi2pdf` in package **tools**.
- unix-alike only**: Set at startup from the environment variable `R_TEXI2DVICMD`, which defaults first to the value of environment variable `TEXI2DVI`, and then to a value set when R was installed (the full path to a `texi2dvi` script if one was found). If necessary, that environment variable can be set to `"emulation"`.
- `timeout`: positive integer. The timeout for some Internet operations, in seconds. Default 60 (seconds) but can be set from environment variable `R_DEFAULT_INTERNET_TIMEOUT`. (Invalid values of the option or the variable are silently ignored: non-integer numeric values will be truncated.) See `download.file` and `connections`.
- `topLevelEnvironment`: see `topenv` and `sys.source`.
- `url.method`: character string: the default method for `url`. Normally unset, which is equivalent to `"default"`, which is `"internal"` except on Windows.
- `useFancyQuotes`: controls the use of directional quotes in `sQuote`, `dQuote` and in rendering text help (see `Rd2txt` in package **tools**). Can be `TRUE`, `FALSE`, `"TeX"` or `"UTF-8"`.
- `verbose`: logical. Should R report extra information on progress? Set to `TRUE` by the command-line option `'--verbose'`.
- `warn`: integer value to set the handling of warning messages by the default warning handler. In the future, this value is checked to be one of -1, 0, 1, 2. For now, setting environment variable `R_WARN_BOUNDS_OPT` to `"yes"` activates that check. If `warn` is negative all warnings are ignored. If `warn` is zero (the default) warnings are stored until the top-level function returns. If 10 or fewer warnings were signalled they will be printed otherwise a message saying how many were signalled. An object called `last.warning` is created and can be printed through the function `warnings`. If `warn` is one, warnings are printed as they occur. If `warn` is two (or larger, coercible to integer), all warnings are turned into errors. While sometimes useful for debugging, turning warnings into errors may trigger bugs and resource leaks that would not have been triggered otherwise.
- `warnPartialMatchArgs`: logical. If true, warns if partial matching is used in argument matching.
- `warnPartialMatchAttr`: logical. If true, warns if partial matching is used in extracting attributes via `attr`.
- `warnPartialMatchDollar`: logical. If true, warns if partial matching is used for extraction by `$`.
- `warning.expression`: an R code expression to be called if a warning is generated, replacing the standard message. If non-null it is called irrespective of the value of option `warn`.
- `warning.length`: sets the truncation limit in bytes for error and warning messages. A non-negative integer, with allowed values 100...8170, default 1000.

nwarnings: the limit for the number of warnings kept when `warn = 0`, default 50. This will discard messages if called whilst they are being collected. If you increase this limit, be aware that the current implementation pre-allocates the equivalent of a named list for them, i.e., do not increase it to more than say a million.

width: controls the maximum number of columns on a line used in printing vectors, matrices and arrays, and when filling by `cat`.

Columns are normally the same as characters except in East Asian languages.

You may want to change this if you re-size the window that R is running in. Valid values are 10...10000 with default normally 80. (The limits on valid values are in file `'Print.h'` and can be changed by re-compiling R.) Some R consoles automatically change the value when they are resized.

See the examples on [Startup](#) for one way to set this automatically from the terminal width when R is started.

The 'factory-fresh' default settings of some of these options are (alphabetically)

<code>add.smooth</code>	TRUE
<code>check.bounds</code>	FALSE
<code>continue</code>	"+"
<code>digits</code>	7
<code>echo</code>	TRUE
<code>encoding</code>	"native.enc"
<code>error</code>	NULL
<code>expressions</code>	5000
<code>keep.source</code>	<code>interactive()</code>
<code>keep.source.pkgs</code>	FALSE
<code>max.print</code>	99999
<code>OutDec</code>	"."
<code>prompt</code>	"> "
<code>quiet</code>	FALSE
<code>scipen</code>	0
<code>show.error.messages</code>	TRUE
<code>timeout</code>	60
<code>verbose</code>	FALSE
<code>warn</code>	0
<code>warning.length</code>	1000
<code>width</code>	80

Others are set from environment variables or are platform-dependent.

Options set in package **grDevices**

These will be set when package **grDevices** (or its namespace) is loaded if not already set.

bitmapType: (Unix only, incl. macOS) character. The default type for the bitmap devices such as [png](#). Defaults to "cairo" on systems where that is available, or to "quartz" on macOS where that is available.

device: a character string giving the name of a function, or the function object itself, which when called creates a new graphics device of the default type for that session. The value of this option defaults to the normal screen device (e.g., X11, windows or quartz) for an interactive session, and pdf in batch use or if a screen is not available. If set to the name

of a device, the device is looked for first from the global environment (that is down the usual search path) and then in the **grDevices** namespace.

The default values in interactive and non-interactive sessions are configurable via environment variables `R_INTERACTIVE_DEVICE` and `R_DEFAULT_DEVICE` respectively.

The search logic for ‘the normal screen device’ is that this is `windows` on Windows, and `quartz` if available on macOS (running at the console, and compiled into the build). Otherwise `X11` is used if environment variable `DISPLAY` is set.

`device.ask.default`: logical. The default for `devAskNewPage("ask")` when a device is opened.

`locatorBell`: logical. Should selection in `locator` and `identify` be confirmed by a bell? Default `TRUE`. Honoured at least on `X11` and `windows` devices.

`windowsTimeouts`: (Windows-only) integer vector of length 2 representing two times in milliseconds. These control the double-buffering of `windows` devices when that is enabled: the first is the delay after plotting finishes (default 100) and the second is the update interval during continuous plotting (default 500). The values at the time the device is opened are used.

Other options used by package **graphics**

`max.contour.segments`: positive integer, defaulting to 25000 if not set. A limit on the number of segments in a single contour line in `contour` or `contourLines`.

Options set (or used) in package **stats**

Most of these will be set when package **stats** (or its namespace) is loaded if not already set.

`contrasts`: the default `contrasts` used in model fitting such as with `aov` or `lm`. A character vector of length two, the first giving the function to be used with unordered factors and the second the function to be used with ordered factors. By default the elements are named `c("unordered", "ordered")`, but the names are unused.

`na.action`: the name of a function for treating missing values (NA's) for certain situations, see `na.action` and `na.pass`.

`show.coef.Pvalues`: logical, affecting whether P values are printed in summary tables of coefficients. See `printCoefmat`.

`show.nls.convergence`: logical, should `nls` convergence messages be printed for successful fits? Initially unset, which means `TRUE`.

`show.signif.stars`: logical, should stars be printed on summary tables of coefficients? See `printCoefmat`.

`str.dendrogram.last`: see `str.dendrogram`.

`ts.eps`: the relative tolerance for certain time series (`ts`) computations. Default `1e-05`.

`ts.S.compat`: logical. Used to select S compatibility for plotting time-series spectra. See the description of argument `log` in `plot.spec`.

Options set (or used) in package **utils**

Many of these will be set when package **utils** (or its namespace) is loaded if not already set.

`BioC_mirror`: The URL of a Bioconductor mirror for use by `setRepositories`, e.g. the default `"https://bioconductor.org"` or the European mirror `"https://bioconductor.statistik.tu-dortmund.de"`. Can be set by `chooseBioCmirror`.

browser: The HTML browser to be used by `browseURL`. This sets the default browser on UNIX or a non-default browser on Windows. Alternatively, an R function that is called with a URL as its argument. See `browseURL` for further details.

ccaddress: default Cc: address used by `create.post` (and hence `bug.report` and `help.request`). Can be `FALSE` or `"`.

citation.bibtex.max: default 1; the maximal number of bibentries (`bibentry`) in a `citation` for which the BibTeX version is printed in addition to the text one.

de.cellwidth: integer: the cell widths (number of characters) to be used in the data editor `dataentry`. If this is unset (the default), 0, negative or NA, variable cell widths are used.

demo.ask: default for the ask argument of `demo`.

editor: a non-empty character string or an R function that sets the default text editor, e.g., for `edit` and `file.edit`. Set from the environment variable `EDITOR` on UNIX, or if unset `VISUAL` or `vi`. As a string it should specify the name of or path to an external command.

example.ask: default for the ask argument of `example`.

help.ports: optional integer vector for setting ports of the internal HTTP server, see `startDynamicHelp`.

help.search.types: default types of documentation to be searched by `help.search` and `??`.

help.try.all.packages: default for an argument of `help`.

help_type: default for an argument of `help`, used also as the help type by `?`.

help.htmlmath: default for the `texmath` argument of `Rd2HTML`, controlling how LaTeX-like mathematical equations are displayed in R help pages (if enabled). Useful values are `"katex"` (equivalent to `NULL`, the default) and `"mathjax"`; for all other values basic substitutions are used.

help.htmltoc: logical: whether a table of contents should be included in dynamic help pages.

HTTPUserAgent: string used as the ‘user agent’ in HTTP(S) requests by `download.file`, `url` and `curlGetHeaders`, or `NULL` when requests will be made without a user agent header. The default is `"R (version platform arch os)"` except when ‘libcurl’ is used when it is `"libcurl/version"` for the ‘libcurl’ version in use. With ‘libcurl’, the `"R"` prefix is reserved: `HTTPUserAgent` with the prefix will be ignored and the default will be used.

install.lock: logical: should per-directory package locking be used by `install.packages`? Most useful for binary installs on macOS and Windows, but can be used in a startup file for source installs via R CMD `INSTALL`. For binary installs, can also be the character string `"pkglock"`.

internet.info: The minimum level of information to be printed on URL downloads etc, using the `"internal"` and `"libcurl"` methods. Default is 2, for failure causes. Set to 1 or 0 to get more detailed information (for the `"internal"` method 0 provides more information than 1).

install.packages.check.source: Used by `install.packages` (and indirectly `update.packages`) on platforms which support binary packages. Possible values `"yes"` and `"no"`, with unset being equivalent to `"yes"`.

install.packages.compile.from.source: Used by `install.packages` (`type = "both"`) (and indirectly `update.packages`) on platforms which support binary packages. Possible values are `"never"`, `"interactive"` (which means ask in interactive use and `"never"` in batch use) and `"always"`. The default is taken from environment variable `R_COMPILE_AND_INSTALL_PACKAGES`, with default `"interactive"` if unset. However, `install.packages` uses `"never"` unless a make program is found, consulting the environment variable `MAKE`.

mailer: default emailing method used by `create.post` and hence `bug.report` and `help.request`.

menu.graphics: Logical: should graphical menus be used if available? Defaults to TRUE. Currently applies to `select.list`, `chooseCRANmirror`, `setRepositories` and to select from multiple (text) help files in `help`.

Ncpus: an integer $n \geq 1$, used in `install.packages` as default for the number of CPUs to use in a potentially parallel installation, as `Ncpus = getOption("Ncpus", 1L)`, i.e., when unset is equivalent to a setting of 1.

pkgType: The default type of packages to be downloaded and installed – see `install.packages`. Possible values are platform dependently

on Windows "win.binary", "source" and "both" (the default).

on Unix-alikes "source" (the default except under a CRAN macOS build), build-specific variants of "mac.binary" (e.g., "mac.binary.big-sur-arm64") or "both" (the default for CRAN macOS builds).

Value "binary" is a synonym for the native binary type (if there is one); "both" is used by `install.packages` to choose between source and binary installs.

repos: character vector of repository URLs for use by `available.packages` and related functions. Initially set from entries marked as default in the 'repositories' file, whose path is configurable via environment variable `R_REPOSITORIES` (set this to NULL to skip initialization at startup). The 'factory-fresh' setting from the file in `R.home("etc")` is `c(CRAN="@CRAN@")`, a value that causes some utilities to prompt for a CRAN mirror. To avoid this do set the CRAN mirror, by something like

```
local({
  r <- getOption("repos")
  r["CRAN"] <- "https://my.local.cran"
  options(repos = r)
})
```

in your '`.Rprofile`', or use a personal 'repositories' file.

Note that you can add more repositories (Bioconductor, R-Forge, RForge.net, ...) for the current session using `setRepositories`.

str: a list of options controlling the default `str` display. Defaults to `strOptions()`.

SweaveHooks, SweaveSyntax: see `Sweave`.

unzip: a character string used by `unzip`: the path of the external program `unzip` or "internal". Defaults (platform dependently)

on unix-alikes to the value of `R_UNZIPCMD`, which is set in 'etc/Renviron' to the path of the `unzip` command found during configuration and otherwise to "".

on Windows to "internal" when the internal `unzip` code is used.

Options set in package parallel

These will be set when package **parallel** (or its namespace) is loaded if not already set.

mc.cores: an integer giving the maximum allowed number of *additional* R processes allowed to be run in parallel to the current R process. Defaults to the setting of the environment variable `MC_CORES` if set. Most applications which use this assume a limit of 2 if it is unset.

Options used on Unix only

dvipscmd: character string giving a command to be used in the (deprecated) off-line printing of help pages *via* PostScript. Defaults to "dvips".

Options used on Windows only

`warn.FPU`: logical, by default undefined. If true, a [warning](#) is produced whenever `dyn.load` repairs the control word damaged by a buggy DLL.

Note

For compatibility with S there is a visible object `.Options` whose value is a pairlist containing the current `options()` (in no particular order). Assigning to it will make a local copy and not change the original. (*Using* it however is faster than calling `options()`).

An option set to `NULL` is indistinguishable from a non existing option.

Examples

```
op <- options(); utils::str(op) # op is a named list

getOption("width") == options()$width # the latter needs more memory
options(digits = 15)
pi

# set the editor, and save previous value
old.o <- options(editor = "nedit")
old.o

options(check.bounds = TRUE, warn = 1)
x <- NULL; x[4] <- "yes" # gives a warning

options(digits = 5)
print(1e5)
options(scipen = 3); print(1e5)

options(op)      # reset (all) initial options
options("digits")

## Not run: ## set contrast handling to be like S
options(contrasts = c("contr.helmert", "contr.poly"))

## End(Not run)

## Not run: ## on error, terminate the R session with error status 66
options(error = quote(q("no", status = 66, runLast = FALSE)))
stop("test it")

## End(Not run)

## Not run: ## Set error actions for debugging:
## enter browser on error, see ?recover:
options(error = recover)
## allows to call debugger() afterwards, see ?debugger:
options(error = dump.frames)
## A possible setting for non-interactive sessions
```

```

options(error = quote({dump.frames(to.file = TRUE); q()}))

## End(Not run)

# Compare the two ways to get an option and use it
# accounting for the possibility it might not be set.
if(as.logical(getOption("performCleanup", TRUE)))
  cat("do cleanup\n")

## Not run:
# a clumsier way of expressing the above w/o the default.
tmp <- getOption("performCleanup")
if(is.null(tmp))
  tmp <- TRUE
if(tmp)
  cat("do cleanup\n")

## End(Not run)

```

order

Ordering Permutation

Description

`order` returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. `sort.list` does the same, using only one argument. See the examples for how to use these functions to sort data frames, etc.

Usage

```

order(..., na.last = TRUE, decreasing = FALSE,
      method = c("auto", "shell", "radix"))

sort.list(x, partial = NULL, na.last = TRUE, decreasing = FALSE,
         method = c("auto", "shell", "quick", "radix"))

```

Arguments

<code>...</code>	a sequence of numeric, complex, character or logical vectors, all of the same length, or a classed R object.
<code>x</code>	an atomic vector for methods "shell" and "quick". When <code>x</code> is a non-atomic R object, the default "auto" and "radix" methods may work if <code>order(x, ..)</code> does.
<code>partial</code>	vector of indices for partial sorting. (Non-NULL values are not implemented.)
<code>decreasing</code>	logical. Should the sort order be increasing or decreasing? For the "radix" method, this can be a vector of length equal to the number of arguments in <code>...</code> and the elements are recycled as necessary. For the other methods, it must be length one.
<code>na.last</code>	for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed (see 'Note'.)

method the method to be used: partial matches are allowed. The default ("auto") implies "radix" for numeric vectors, integer vectors, logical vectors and factors with fewer than 2^{31} elements. Otherwise, it implies "shell". For details of methods "shell", "quick", and "radix", see the help for [sort](#).

Details

In the case of ties in the first vector, values in the second are used to break the ties. If the values are still tied, values in the later arguments are used to break the tie (see the first example). The sort used is *stable* (except for `method = "quick"`), so any unresolved ties will be left in their original ordering.

Complex values are sorted first by the real part, then the imaginary part.

Except for method "radix", the sort order for character vectors will depend on the collating sequence of the locale in use: see [Comparison](#).

The "shell" method is generally the safest bet and is the default method, except for short factors, numeric vectors, integer vectors and logical vectors, where "radix" is assumed. Method "radix" stably sorts logical, numeric and character vectors in linear time. It outperforms the other methods, although there are drawbacks, especially for character vectors (see [sort](#)). Method "quick" for `sort.list` is only supported for numeric `x` with `na.last = NA`, is not stable, and is slower than "radix".

`partial = NULL` is supported for compatibility with other implementations of S, but no other values are accepted and ordering is always complete.

For a classed R object, the sort order is taken from `xtfrm`: as its help page notes, this can be slow unless a suitable method has been defined or `is.numeric(x)` is true. For factors, this sorts on the internal codes, which is particularly appropriate for ordered factors.

Value

An integer vector unless any of the inputs has 2^{31} or more elements, when it is a double vector.

Warning

In programmatic use it is unsafe to name the `...` arguments, as the names could match current or future control arguments such as `decreasing`. A sometimes-encountered unsafe practice is to call `do.call('order', df_obj)` where `df_obj` might be a data frame: copy `df_obj` and remove any names, for example using [unname](#).

Note

`sort.list` can get called by mistake as a method for [sort](#) with a list argument: it gives a suitable error message for list `x`.

There is a historical difference in behaviour for `na.last = NA`: `sort.list` removes the NAs and then computes the order amongst the remaining elements: `order` computes the order amongst the non-NA elements of the original vector. Thus

```
x[order(x, na.last = NA)]
zz <- x[!is.na(x)]; zz[sort.list(x, na.last = NA)]
```

both sort the non-NA values of `x`.

Prior to R 3.3.0 `method = "radix"` was only supported for integers of range less than 100,000.

Examples

```
require(stats)

(ii <- order(x <- c(1,1,3:1,1:4,3), y <- c(9,9:1), z <- c(2,1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x, y, z)[,ii] # shows the reordering (ties via 2nd & 3rd arg)

## Suppose we wanted descending order on y.
## A simple solution for numeric 'y' is
rbind(x, y, z)[, order(x, -y, z)]
## More generally we can make use of xtfrm
cy <- as.character(y)
rbind(x, y, z)[, order(x, -xtfrm(cy), z)]
## The radix sort supports multiple 'decreasing' values:
rbind(x, y, z)[, order(x, cy, z, decreasing = c(FALSE, TRUE, FALSE),
                      method="radix")]

## Sorting data frames:
dd <- transform(data.frame(x, y, z),
                 z = factor(z, labels = LETTERS[9:1]))
## Either as above {for factor 'z' : using internal coding}:
dd[ order(x, -y, z), ]
## or along 1st column, ties along 2nd, ... *arbitrary* no.{columns}:
dd[ do.call(order, dd), ]

set.seed(1) # reproducible example:
d4 <- data.frame(x = round( rnorm(100)), y = round(10*runif(100)),
                 z = round( 8*rnrm(100)), u = round(50*runif(100)))
(d4s <- d4[ do.call(order, d4), ])
(i <- which(diff(d4s[, 3]) == 0))
# in 2 places, needed 3 cols to break ties:
d4s[ rbind(i, i+1), ]

## rearrange matched vectors so that the first is in ascending order
x <- c(5:1, 6:8, 12:9)
y <- (x - 5)^2
o <- order(x)
rbind(x[o], y[o])

## tests of na.last
a <- c(4, 3, 2, NA, 1)
b <- c(4, NA, 2, 7, 1)
z <- cbind(a, b)
(o <- order(a, b)); z[o, ]
(o <- order(a, b, na.last = FALSE)); z[o, ]
```

```
(o <- order(a, b, na.last = NA)); z[o, ]

## speed examples on an average laptop for long vectors:
## factor/small-valued integers:
x <- factor(sample(letters, 1e7, replace = TRUE))
system.time(o <- sort.list(x, method = "quick", na.last = NA)) # 0.1 sec
stopifnot(!is.unsorted(x[o]))
system.time(o <- sort.list(x, method = "radix")) # 0.05 sec, 2X faster
stopifnot(!is.unsorted(x[o]))
## large-valued integers:
xx <- sample(1:200000, 1e7, replace = TRUE)
system.time(o <- sort.list(xx, method = "quick", na.last = NA)) # 0.3 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.2 sec
## character vectors:
xx <- sample(state.name, 1e6, replace = TRUE)
system.time(o <- sort.list(xx, method = "shell")) # 2 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.007 sec, 300X faster
## double vectors:
xx <- rnorm(1e6)
system.time(o <- sort.list(xx, method = "shell")) # 0.4 sec
system.time(o <- sort.list(xx, method = "quick", na.last = NA)) # 0.1 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.05 sec, 2X faster
```

outer

Outer Product of Arrays

Description

The outer product of the arrays `X` and `Y` is the array `A` with dimension `c(dim(X), dim(Y))` where element `A[c(arrayindex.x, arrayindex.y)] = FUN(X[arrayindex.x], Y[arrayindex.y], ...)`.

Usage

```
outer(X, Y, FUN = "*", ...)
X %o% Y
```

Arguments

<code>X, Y</code>	first and second arguments for function <code>FUN</code> . Typically a vector or array.
<code>FUN</code>	a function to use on the outer products, found <i>via</i> match.fun (except for the special case <code>"*"</code>).
<code>...</code>	optional arguments to be passed to <code>FUN</code> .

Details

`X` and `Y` must be suitable arguments for `FUN`. Each will be extended by [rep](#) to length the products of the lengths of `X` and `Y` before `FUN` is called.

`FUN` is called with these two extended vectors as arguments (plus any arguments in `...`). It must be a vectorized function (or the name of one) expecting at least two arguments and returning a value with the same length as the first (and the second).

Where they exist, the `[dim]names` of `X` and `Y` will be copied to the answer, and a dimension assigned which is the concatenation of the dimensions of `X` and `Y` (or lengths if dimensions do not exist).

`FUN = "*"` is handled as a special case *via* `as.vector(X) %*% t(as.vector(Y))`, and is intended only for numeric vectors and arrays.

`%o%` is binary operator providing a wrapper for `outer(x, y, "*")`.

See Also

`%*%` for usual (*inner*) matrix vector multiplication; `kronecker` which is based on `outer`; `Vectorize` for vectorizing a non-vectorized function.

Examples

```
x <- 1:9; names(x) <- x
# Multiplication & Power Tables
x %o% x
y <- 2:8; names(y) <- paste(y, ":", sep = "")
outer(y, x, `^`)

outer(month.abb, 1999:2003, FUN = paste)

## three way multiplication table:
x %o% x %o% y[1:3]
```

Paren

Parentheses and Braces

Description

Open parenthesis, `(`, and open brace, `{`, are `.Primitive` functions in R.

Effectively, `(` is semantically equivalent to the identity `function(x) x`, whereas `{` is slightly more interesting, see examples.

Usage

```
( ... )

{ ... }
```

Value

For `(`, the result of evaluating the argument. This has visibility set, so will auto-print if used at top-level.

For `{`, the result of the last expression evaluated. This has the visibility of the last evaluation.

f <- get("(")
e <- expression(3 + 2 * 4)
identical(f(e), e)

do <- get("{")
do(x <- 3, y <- 2*x-3, 6-x-y); x; y

## note the differences
(2+3)
{2+3; 4+5}
(invisible(2+3))
{invisible(2+3)}
```

parse

Parse R Expressions

Description

`parse()` returns the parsed but unevaluated expressions in an [expression](#), a “list” of [calls](#).
`str2expression(s)` and `str2lang(s)` return special versions of `parse(text=s, keep.source=FALSE)` and can therefore be regarded as transforming character strings `s` to expressions, calls, etc.

Usage

```
parse(file = "", n = NULL, text = NULL, prompt = "?",
      keep.source = getOption("keep.source"), srcfile,
      encoding = "unknown")

str2lang(s)
str2expression(text)
```

Arguments

<code>file</code>	a connection , or a character string giving the name of a file or a URL to read the expressions from. If <code>file</code> is "" and <code>text</code> is missing or <code>NULL</code> then input is taken from the console.
<code>n</code>	integer (or coerced to integer). The maximum number of expressions to parse. If <code>n</code> is <code>NULL</code> or negative or <code>NA</code> the input is parsed in its entirety.

<code>text</code>	character vector. The text to parse. Elements are treated as if they were lines of a file. Other R objects will be coerced to character if possible.
<code>prompt</code>	the prompt to print when parsing from the keyboard. <code>NULL</code> means to use R's prompt, <code>getOption("prompt")</code> .
<code>keep.source</code>	a logical value; if <code>TRUE</code> , keep source reference information.
<code>srcfile</code>	<code>NULL</code> , a character vector, or a <code>srcfile</code> object. See the 'Details' section.
<code>encoding</code>	encoding to be assumed for input strings. If the value is <code>"latin1"</code> or <code>"UTF-8"</code> it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection <code>con</code> or <i>via</i> <code>options(encoding=)</code> : see the example under <code>file</code> . Arguments <code>encoding = "UTF-8"</code> and <code>encoding = "latin1"</code> are ignored with a warning when running, respectively, in a non-UTF-8 MBCS locale or in an MBCS locale.
<code>s</code>	a <code>character</code> vector of length 1, i.e., a "string".

Details

`parse(...)`: If `text` has length greater than zero (after coercion) it is used in preference to `file`.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic Mac OS). The final line can be incomplete, that is missing the final EOL marker.

When input is taken from the console, `n = NULL` is equivalent to `n = 1`, and `n < 0` will read until an EOF character is read. (The EOF character is Ctrl-Z for the Windows front-ends.) The line-length limit is 4095 bytes when reading from the console (which may impose a lower limit).

The default for `srcfile` is set as follows. If `keep.source` is not `TRUE`, `srcfile` defaults to a character string, either `"<text>"` or one derived from `file`. When `keep.source` is `TRUE`, if `text` is used, `srcfile` will be set to a `srcfilecopy` containing the text. If a character string is used for `file`, a `srcfile` object referring to that file will be used.

When `srcfile` is a character string, error messages will include the name, but source reference information will not be added to the result. When `srcfile` is a `srcfile` object, source reference information will be retained.

`str2expression(s)`: for a `character` vector `s`, `str2expression(s)` corresponds to `parse(text = s, keep.source=FALSE)`, which is always of type (`typeof`) and `class` expression.

`str2lang(s)`: for a `character` string `s`, `str2lang(s)` corresponds to `parse(text = s, keep.source=FALSE) [[1]]` (plus a check that both `s` and the `parse(*)` result are of length one) which is typically a `call` but may also be a symbol aka `name`, `NULL` or an atomic constant such as `2`, `1L`, or `TRUE`. Put differently, the value of `str2lang(.)` is a `call` or one of its parts, in short "a `call` or simpler".

Currently, encoding is not handled in `str2lang()` and `str2expression()`.

Value

`parse()` and `str2expression()` return an object of type `"expression"`, for `parse()` with up to `n` elements if specified as a non-negative integer.

`str2lang(s)`, `s` a string, returns "a `call` or simpler", see the 'Details:' section.

When `srcfile` is non-NULL, a `"srcref"` attribute will be attached to the result containing a list of [srcref](#) records corresponding to each element, a `"srcfile"` attribute will be attached containing a copy of `srcfile`, and a `"wholeSrcref"` attribute will be attached containing a [srcref](#) record corresponding to all of the parsed text. Detailed parse information will be stored in the `"srcfile"` attribute, to be retrieved by [getParseData](#).

A syntax error (including an incomplete expression) will throw an error.

Character strings in the result will have a declared encoding if `encoding` is `"latin1"` or `"UTF-8"`, or if `text` is supplied with every element of known encoding in a Latin-1 or UTF-8 locale.

Partial parsing

When a syntax error occurs during parsing, `parse` signals an error. The partial parse data will be stored in the `srcfile` argument if it is a [srcfile](#) object and the `text` argument was used to supply the text. In other cases it will be lost when the error is triggered.

The partial parse data can be retrieved using [getParseData](#) applied to the `srcfile` object. Because parsing was incomplete, it will typically include references to `"parent"` entries that are not present.

Note

Using `parse(text = *, ...)` or its simplified and hence more efficient versions `str2lang()` or `str2expression()` is at least an order of magnitude less efficient than `call(...)` or `as.call()`.

The source reference information can be used for debugging (see e.g. [setBreakpoint](#)) and profiling (see [Rprof](#)). It can be examined by [getSrcref](#) and related functions. More detailed information is available through [getParseData](#).

Examples

```
fil <- tempfile(fileext = ".Rdmped")
cat("x <- c(1, 4)\n x ^ 3 -10 ; outer(1:7, 5:9)\n", file = fil)
# parse 3 statements from our temp file
parse(file = fil, n = 3)
unlink(fil)

## str2lang(<string>) || str2expression(<character>) :
stopifnot(exprs = {
  identical( str2lang("x[3] <- 1+4"), quote(x[3] <- 1+4))
  identical( str2lang("log(y)"),      quote(log(y)) )
  identical( str2lang("abc" ),        quote(abc) -> qa)
  is.symbol(qa) & !is.call(qa)        # a symbol/name, not a call
  identical( str2lang("1.375" ), 1.375) # just a number, not a call
```

```

    identical( str2expression(c("# a comment", "", "42")), expression(42) )
  })

# A partial parse with a syntax error
txt <- "
x <- 1
an error
"
sf <- srcfile("txt")
tryCatch(parse(text = txt, srcfile = sf), error = function(e) "Syntax error.")
getParseData(sf)

```

paste

Concatenate Strings

Description

Concatenate vectors after converting to character. Concatenation happens in two basically different ways, determined by `collapse` being a string or not.

Usage

```

paste (... , sep = " ", collapse = NULL, recycle0 = FALSE)
paste0(... , collapse = NULL, recycle0 = FALSE)

```

Arguments

<code>...</code>	one or more R objects, to be converted to character vectors.
<code>sep</code>	a character string to separate the terms. Not NA_character_ .
<code>collapse</code>	an optional character string to separate the results. Not NA_character_ . When <code>collapse</code> is a string, the result is always a string (character of length 1).
<code>recycle0</code>	logical indicating if zero-length character arguments should result in the zero-length character (0). Note that when <code>collapse</code> is a string, <code>recycle0</code> does <i>not</i> recycle to zero-length, but to <code>" "</code> .

Details

`paste` converts its arguments (via [as.character](#)) to character strings, and concatenates them (separating them by the string given by `sep`).

If the arguments are vectors, they are concatenated term-by-term to give a character vector result. Vector arguments are recycled as needed. Zero-length arguments are recycled as `" "` unless `recycle0` is `TRUE` and `collapse` is `NULL`.

Note that `paste()` coerces [NA_character_](#), the character missing value, to `"NA"` which may seem undesirable, e.g., when pasting two character vectors, or very desirable, e.g. in `paste("the value of pi is ", pi)`.

`paste0(... , collapse)` is equivalent to `paste(... , sep = "", collapse)`, slightly more efficiently.

If a value is specified for `collapse`, the values in the result are then concatenated into a single string, with the elements being separated by the value of `collapse`.

Value

A character vector of the concatenated values. This will be of length zero if all the objects are, unless `collapse` is non-NULL, in which case it is "" (a single empty string).

If any input into an element of the result is in UTF-8 (and none are declared with encoding "bytes", see [Encoding](#)), that element will be in UTF-8, otherwise in the current encoding in which case the encoding of the element is declared if the current locale is either Latin-1 or UTF-8, at least one of the corresponding inputs (including separators) had a declared encoding and all inputs were either ASCII or declared.

If an input into an element is declared with encoding "bytes", no translation will be done of any of the elements and the resulting element will have encoding "bytes". If `collapse` is non-NULL, this applies also to the second, collapsing, phase, but some translation may have been done in pasting object together in the first phase.

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`toString` typically calls `paste(*, collapse="")`. String manipulation with `as.character`, `substr`, `nchar`, `strsplit`; further, `cat` which concatenates and writes to a file, and `sprintf` for C like string construction.

'`plotmath`' for the use of `paste` in plot annotation.

Examples

```
## When passing a single vector, paste0 and paste work like as.character.
paste0(1:12)
paste(1:12)          # same
as.character(1:12)   # same

## If you pass several vectors to paste0, they are concatenated in a
## vectorized way.
(nth <- paste0(1:12, c("st", "nd", "rd", rep("th", 9))))

## paste works the same, but separates each input with a space.
## Notice that the recycling rules make every input as long as the longest input.
paste(month.abb, "is the", nth, "month of the year.")
paste(month.abb, letters)

## You can change the separator by passing a sep argument
## which can be multiple characters.
paste(month.abb, "is the", nth, "month of the year.", sep = "_*_")

## To collapse the output into a single string, pass a collapse argument.
paste0(nth, collapse = ", ")

## For inputs of length 1, use the sep argument rather than collapse
paste("1st", "2nd", "3rd", collapse = ", ") # probably not what you wanted
paste("1st", "2nd", "3rd", sep = ", ")

## You can combine the sep and collapse arguments together.
paste(month.abb, nth, sep = ": ", collapse = "; ")
```

```
## Using paste() in combination with strwrap() can be useful
## for dealing with long strings.
(title <- paste(strwrap(
  "Stopping distance of cars (ft) vs. speed (mph) from Ezekiel (1930)",
  width = 30), collapse = "\n"))
plot(dist ~ speed, cars, main = title)

## zero length arguments recycled as `""` -- NB: `{}` <==> character(0) here
paste({}, 1:2)

## 'recycle0 = TRUE' allows standard vectorized behaviour, i.e., zero-length
## recycling resulting in zero-length result character(0):
valid <- FALSE
val <- pi
paste("The value is", val[valid], "-- not so good!") # -> ".. value is -- not .."
paste("The value is", val[valid], "-- good: empty!", recycle0=TRUE) # -> character(0)

## When 'collapse = <string>', result is (length 1) string in all cases
paste("foo", {}, "bar", collapse = "|") # |--> "foo bar"
paste("foo", {}, collapse = "|", recycle0 = TRUE) # |--> ""
## If all arguments are empty (and collapse a string), "" results always
paste(collapse = "|")
paste(collapse = "|", recycle0 = TRUE)
paste({}, collapse = "|")
paste({}, collapse = "|", recycle0 = TRUE)
```

path.expand

Expand File Paths

Description

Expand a path name, for example by replacing a leading tilde by the user's home directory (if defined on that platform).

Usage

```
path.expand(path)
```

Arguments

path character vector containing one or more path names.

Details

On Unix - alike: On most builds of R a leading `~user` will expand to the home directory of `user`.

There are possibly different concepts of 'home directory': that usually used is the setting of the environment variable `HOME`.

The 'path names' need not exist nor be valid path names but they do need to be representable in the session encoding.

On Windows: The ‘home’ directory is taken from the `R_USER` environment variable (or possibly `HOME` if `R_USER` is not set) when `path.expand` is first called in a session. See “[What are HOME and working directories?](#)” in *R for Windows FAQ* for further details.

The ‘path names’ need not exist nor be valid path names.

Value

A character vector of possibly expanded path names: where the home directory is unknown or none is specified the path is returned unchanged.

If the expansion would exceed the maximum path length the result may be truncated or the path may be returned unchanged.

See Also

`basename`, `normalizePath`, `file.path`.

Examples

```
path.expand("~/foo")
```

pcre_config

Report Configuration Options for PCRE

Description

Report some of the configuration options of the version of PCRE in use in this R session.

Usage

```
pcre_config()
```

Value

A named logical vector, currently with elements

UTF-8	Support for UTF-8 inputs. Required.
Unicode properties	Support for ‘\p{xx}’ and ‘\P{xx}’ in regular expressions. Desirable and used by some CRAN packages. As of PCRE2, always present with support for UTF-8.
JIT	Support for just-in-time compilation. Desirable for speed (but only available as a compile-time option on certain architectures, and may be unused as unreliable on some of those, e.g. arm64).
stack	Does match recursion use a stack (TRUE, the default for PCRE1 and PCRE2 older than 10.30) or a heap? See the discussion at https://www.pcre.org/original/doc/html/pcrestack.html (Added in R 3.4.0.). No longer relevant and always FALSE in PCRE2 since version 10.30 which no longer uses function recursion to remember backtracking positions.

See Also

`extSoftVersion` for the PCRE version.

Examples

```
pcre_config()
```

```
pipeOp
```

Forward Pipe Operator

Description

Pipe a value into a call expression or a function expression.

Usage

```
lhs |> rhs
```

Arguments

lhs	expression producing a value.
rhs	a call expression.

Details

A pipe expression passes, or ‘pipes’, the result of the left-hand-side expression `lhs` to the right-hand-side expression `rhs`.

The `lhs` is inserted as the first argument in the call. So `x |> f(y)` is interpreted as `f(x, y)`.

To avoid ambiguities, functions in `rhs` calls may not be syntactically special, such as `+` or `if`.

It is also possible to use a named argument with the placeholder `_` in the `rhs` call to specify where the `lhs` is to be inserted. The placeholder can only appear once on the `rhs`.

The placeholder can also be used as the first argument in an extraction call, such as `_$coef`. More generally, it can be used as the head of a chain of extractions, such as `_$coef[[2]]`, using a sequence of the extraction functions `$`, `[`, `[[`, or `@`.

Pipe notation allows a nested sequence of calls to be written in a way that may make the sequence of processing steps easier to follow.

Currently, pipe operations are implemented as syntax transformations. So an expression written as `x |> f(y)` is parsed as `f(x, y)`. It is worth emphasizing that while the code in a pipeline is written sequentially, regular R semantics for evaluation apply and so piped expressions will be evaluated only when first used in the `rhs` expression.

Value

Returns the result of evaluating the transformed expression.

Background

The forward pipe operator is motivated by the pipe introduced in the **magrittr** package, but is more streamlined. It is similar to the pipe or pipeline operators introduced in other languages, including F#, Julia, and JavaScript.

Warning

This was introduced in R 4.1.0. Code using it will not be parsed as intended (probably with an error) in earlier versions of R.

Examples

```
# simple uses:
mtcars |> head()                # same as head(mtcars)
mtcars |> head(2)               # same as head(mtcars, 2)
mtcars |> subset(cyl == 4) |> nrow() # same as nrow(subset(mtcars, cyl == 4))

# to pass the lhs into an argument other than the first, either
# use the _ placeholder with a named argument:
mtcars |> subset(cyl == 4) |> lm(mpg ~ disp, data = _)
# or use an anonymous function:
mtcars |> subset(cyl == 4) |> (function(d) lm(mpg ~ disp, data = d))()
mtcars |> subset(cyl == 4) |> (\(d) lm(mpg ~ disp, data = d))()
# or explicitly name the argument(s) before the "one":
mtcars |> subset(cyl == 4) |> lm(formula = mpg ~ disp)

# using the placeholder as the head of an extraction chain:
mtcars |> subset(cyl == 4) |> lm(formula = mpg ~ disp) |> _$coef[[2]]

# the pipe operator is implemented as a syntax transformation:
quote(mtcars |> subset(cyl == 4) |> nrow())

# regular R evaluation semantics apply
stop() |> (function(...) {}()) # stop() is not used on RHS so is not evaluated
```

plot

*Generic X-Y Plotting***Description**

Generic function for plotting of R objects.

For simple scatter plots, `plot.default` will be used. However, there are `plot` methods for many R objects, including `functions`, `data.frames`, `density` objects, etc. Use `methods(plot)` and the documentation for these. Most of these methods are implemented using traditional graphics (the **graphics** package), but this is not mandatory.

For more details about graphical parameter arguments used by traditional graphics, see [par](#).

Usage

```
plot(x, y, ...)
```

Arguments

<code>x</code>	the coordinates of points in the plot. Alternatively, a single plotting structure, function or <i>any R object with a plot method</i> can be provided.
<code>y</code>	the y coordinates of points in the plot, <i>optional</i> if <code>x</code> is an appropriate structure.
<code>...</code>	arguments to be passed to methods, such as graphical parameters (see par). Many methods will accept the following arguments:

`type` what type of plot should be drawn. Possible types are

- "p" for **p**oints,
- "l" for **l**ines,
- "b" for **b**oth,
- "c" for the lines part alone of "b",
- "o" for both 'overplotted',
- "h" for 'histogram' like (or 'high-density') vertical lines,
- "s" for stair steps,
- "S" for other steps, see 'Details' below,
- "n" for no plotting.

All other types give a warning or an error; using, e.g., `type = "punkte"` being equivalent to `type = "p"` for S compatibility. Note that some methods, e.g. `plot.factor`, do not accept this.

`main` an overall title for the plot: see `title`.

`sub` a subtitle for the plot: see `title`.

`xlab` a title for the x axis: see `title`.

`ylab` a title for the y axis: see `title`.

`asp` the y/x aspect ratio, see `plot.window`.

Details

The two step types differ in their x-y preference: Going from (x_1, y_1) to (x_2, y_2) with $x_1 < x_2$, `type = "s"` moves first horizontal, then vertical, whereas `type = "S"` moves the other way around.

Note

The `plot` generic was moved from the **graphics** package to the **base** package in R 4.0.0. It is currently re-exported from the **graphics** namespace to allow packages importing it from there to continue working, but this may change in future versions of R.

See Also

`plot.default`, `plot.formula` and other methods; `points`, `lines`, `par`. For thousands of points, consider using `smoothScatter()` instead of `plot()`.

For X-Y-Z plotting see `contour`, `persp` and `image`.

Examples

```
require(stats) # for lowess, rpois, rnorm
require(graphics) # for plot methods
plot(cars)
lines(lowess(cars))

plot(sin, -pi, 2*pi) # see ?plot.function

## Discrete Distribution Plot:
plot(table(rpois(100, 5)), type = "h", col = "red", lwd = 10,
      main = "rpois(100, lambda = 5)")

## Simple quantiles/ECDF, see ecdf() {library(stats)} for a better one:
plot(x <- sort(rnorm(47)), type = "s", main = "plot(x, type = \"s\")")
points(x, cex = .5, col = "dark red")
```

pmatch

Partial String Matching

Description

pmatch seeks matches for the elements of its first argument among those of its second.

Usage

```
pmatch(x, table, nomatch = NA_integer_, duplicates.ok = FALSE)
```

Arguments

x	the values to be matched: converted to a character vector by <code>as.character</code> . Long vectors are supported.
table	the values to be matched against: converted to a character vector. Long vectors are not supported.
nomatch	the value to be returned at non-matching or multiply partially matching positions. Note that it is coerced to <code>integer</code> .
duplicates.ok	should elements in <code>table</code> be used more than once?

Details

The behaviour differs by the value of `duplicates.ok`. Consider first the case if this is true. First exact matches are considered, and the positions of the first exact matches are recorded. Then unique partial matches are considered, and if found recorded. (A partial match occurs if the whole of the element of `x` matches the beginning of the element of `table`.) Finally, all remaining elements of `x` are regarded as unmatched. In addition, an empty string can match nothing, not even an exact match to an empty string. This is the appropriate behaviour for partial matching of character indices, for example.

If `duplicates.ok` is `FALSE`, values of `table` once matched are excluded from the search for subsequent matches. This behaviour is equivalent to the R algorithm for argument matching, except for the consideration of empty strings (which in argument matching are matched after exact and partial matching to any remaining arguments).

`charmatch` is similar to `pmatch` with `duplicates.ok` true, the differences being that it differentiates between no match and an ambiguous partial match, it does match empty strings, and it does not allow multiple exact matches.

NA values are treated as if they were the string constant "NA".

Value

An integer vector (possibly including NA if `nomatch = NA`) of the same length as `x`, giving the indices of the elements in `table` which matched, or `nomatch`.

See Also

`match`, `charmatch` and `match.arg`, `match.fun`, `match.call`, for function argument matching etc., `startsWith` for particular checking of initial matches; `grep` etc for more general (regexp) matching of strings.

Examples

```
pmatch("", "") # returns NA
pmatch("m", c("mean", "median", "mode")) # returns NA
pmatch("med", c("mean", "median", "mode")) # returns 2

pmatch(c("", "ab", "ab"), c("abc", "ab"), duplicates.ok = FALSE)
pmatch(c("", "ab", "ab"), c("abc", "ab"), duplicates.ok = TRUE)
## compare
charmatch(c("", "ab", "ab"), c("abc", "ab"))
```

polyroot

*Find Zeros of a Real or Complex Polynomial***Description**

Find zeros of a real or complex polynomial.

Usage

```
polyroot(z)
```

Arguments

`z` the vector of polynomial coefficients in increasing order.

Details

A polynomial of degree $n - 1$,

$$p(x) = z_1 + z_2x + \dots + z_nx^{n-1}$$

is given by its coefficient vector `z[1:n]`. `polyroot` returns the $n - 1$ complex zeros of $p(x)$ using the Jenkins-Traub algorithm.

If the coefficient vector `z` has zeroes for the highest powers, these are discarded.

There is no maximum degree, but numerical stability may be an issue for all but low-degree polynomials.

Value

A complex vector of length $n - 1$, where n is the position of the largest non-zero element of `z`.

Source

C translation by Ross Ihaka of Fortran code in the reference, with modifications by the R Core Team.

References

[uniroot](#) for numerical root finding of arbitrary functions; [complex](#).

Examples

```
polyroot(c(1, 2, 1))
round(polyroot(choose(8, 0:8)), 11) # guess what!
for (n1 in 1:4) print(polyroot(1:n1), digits = 4)
polyroot(c(1, 2, 1, 0, 0)) # same as the first
```

pos.to.env

Convert Positions in the Search Path to Environments

Description

Returns the environment at a specified position in the search path.

Usage

```
pos.to.env(x)
```

Arguments

x an integer between 1 and `length(search())`, the length of the search path, or -1.

Details

Several R functions for manipulating objects in environments (such as [get](#) and [ls](#)) allow specifying environments via corresponding positions in the search path. `pos.to.env` is a convenience function for programmers which converts these positions to corresponding environments; users will typically have no need for it. It is [primitive](#).

-1 is interpreted as the environment the function is called from.

This is a [primitive](#) function.

Examples

```
pos.to.env(1) # R_GlobalEnv
# the next returns the base environment
pos.to.env(length(search()))
```

Description

Compute a sequence of about $n+1$ equally spaced ‘round’ values which cover the range of the values in x . The values are chosen so that they are 1, 2 or 5 times a power of 10.

Usage

```
pretty(x, ...)
```

```
## Default S3 method:
pretty(x, n = 5, min.n = n %/% 3, shrink.sml = 0.75,
       high.u.bias = 1.5, u5.bias = .5 + 1.5*high.u.bias,
       eps.correct = 0, f.min = 2^-20, bounds = TRUE, ...)
```

```
.pretty(x, n = 5L, min.n = n %/% 3, shrink.sml = 0.75,
        high.u.bias = 1.5, u5.bias = .5 + 1.5*high.u.bias,
        eps.correct = 0L, f.min = 2^-20, bounds = TRUE)
```

Arguments

<code>x</code>	an object coercible to numeric by <code>as.numeric</code> .
<code>n</code>	integer giving the <i>desired</i> number of intervals. Non-integer values are rounded down.
<code>min.n</code>	nonnegative integer giving the <i>minimal</i> number of intervals. If <code>min.n == 0</code> , <code>pretty(.)</code> may return a single value.
<code>shrink.sml</code>	positive number, a factor (smaller than one) by which a default scale is shrunk in the case when <code>range(x)</code> is very small (usually 0).
<code>high.u.bias</code>	non-negative numeric, typically > 1 . The interval unit is determined as $\{1,2,5,10\}$ times b , a power of 10. Larger <code>high.u.bias</code> values favor larger units.
<code>u5.bias</code>	non-negative numeric multiplier favoring factor 5 over 2. Default and ‘optimal’: <code>u5.bias = .5 + 1.5*high.u.bias</code> .
<code>eps.correct</code>	integer code, one of $\{0,1,2\}$. If non-0, an <i>epsilon correction</i> is made at the boundaries such that the result boundaries will be outside <code>range(x)</code> ; in the <i>small</i> case, this correction happens only if <code>eps.correct >= 2</code> , allowing <code>eps.correct = 2</code> to reproduce how R’s graphics engine computes axis tick locations, see ‘Details’.
<code>f.min</code>	positive factor multiplied by <code>.Machine\$double.xmin</code> to get the smallest “acceptable” cell c_m which determines the unit of the algorithm. Smaller cell values are set to c_n signalling a warning about being “corrected”. New from R 4.2.0; previously <code>f.min = 20</code> was hardcoded in the algorithm.
<code>bounds</code>	a logical indicating if the resulting vector should <i>cover</i> the full <code>range(x)</code> , i.e., strictly include the bounds of x . New from R 4.2.0, allowing <code>bounds=FALSE</code> to reproduce how R’s graphics engine computes axis extents and tick locations, see ‘Details’; also, for <code>.pretty()</code> , it determines which parts of the C level computations should be returned.
<code>...</code>	further arguments for methods; unused in default method.

Details

`pretty` ignores non-finite values in `x`.

Let $d \leftarrow \max(x) - \min(x) \geq 0$. If d is not (very close to) 0, we let $c \leftarrow d/n$, otherwise more or less $c \leftarrow \max(\text{abs}(\text{range}(x))) * \text{shrink.sml} / \min.n$. Then, the 10 base b is $10^{\lfloor \log_{10}(c) \rfloor}$ such that $b \leq c < 10b$.

Now determine the basic *unit* u as one of $\{1, 2, 5, 10\}b$, depending on $c/b \in [1, 10)$ and the two ‘bias’ coefficients, $h = \text{high.u.bias}$ and $f = \text{u5.bias}$.

.....

R’s graphics engine `GEPretty()` C function calls `R_pretty()` and is used in both packages **graphics** and **grid** (and hence **lattice**, **ggplot2**, etc.) for axis range and tick computations. For these, partly for back compatibility reasons, the optional arguments are set, corresponding to

```
(min.n = 1, shrink.sml = 0.25, high.u.bias = 0.8, u5.bias = 1.7,
 f.min = 1.125, eps.correct = 2, bounds = FALSE)
```

Value

`pretty()` returns a numeric vector of *approximately* n increasing numbers which are “pretty” in decimal notation. (in extreme range cases, the numbers can no longer be “pretty” given the other constraints; e.g., for `pretty(...)`) For ease of investigating the underlying `CR_pretty()` function, `.pretty()` returns a named **list**. By default, when `bounds=TRUE`, the entries are `l`, `u`, and `n`, whereas for `bounds=FALSE`, they are `ns`, `nu`, `n`, and (a “pretty”) unit where the n ’s are integer valued (but only `n` is of class **integer**). Programmers may use this to create pretty sequence (iterator) objects.

See Also

[axTicks](#) for the computation of pretty axis tick locations in plots, particularly on the log scale.

Examples

```
pretty(1:15)                # 0  2  4  6  8 10 12 14 16
pretty(1:15, high.u.bias = 2) # 0  5 10 15
pretty(1:15, n = 4)          # 0  5 10 15
pretty(1:15 * 2)              # 0  5 10 15 20 25 30
pretty(1:20)                  # 0  5 10 15 20
pretty(1:20, n = 2)           # 0 10 20
pretty(1:20, n = 10)          # 0  2  4 ... 20

for(k in 5:11) {
  cat("k=", k, ": "); print(diff(range(pretty(100 + c(0, pi*10^-k)))))}

##-- more bizarre, when min(x) == max(x):
pretty(pi)

add.names <- function(v) { names(v) <- paste(v); v }
utils::str(lapply(add.names(-10:20), pretty))
## min.n = 0 returns a length-1 vector "if pretty":
```

```
utils::str(lapply(add.names(0:20), pretty, min.n = 0))
sapply(  add.names(0:20),  pretty, min.n = 4)

pretty(1.234e100)
pretty(1001.1001)
pretty(1001.1001, shrink.sml = 0.2)
for(k in -7:3)
  cat("shrink=", formatC(2^k, width = 9), ":",
      formatC(pretty(1001.1001, shrink.sml = 2^k), width = 6), "\n")
```

Primitive

Look Up a Primitive Function

Description

`.Primitive` looks up by name a ‘primitive’ (internally implemented) function.

Usage

```
.Primitive(name)
```

Arguments

name name of the R function.

Details

The advantage of `.Primitive` over `.Internal` functions is the potential efficiency of argument passing, and that positional matching can be used where desirable, e.g. in `switch`. For more details, see the Chapter “[.Internal vs .Primitive](#)” in *R Internals*.

All primitive functions are in the base namespace.

You cannot set `attributes` on primitive functions.

This function is almost never used: ``name`` or, more carefully, `get(name, envir = baseenv())` work equally well and do not depend on knowing which functions are primitive (which does change as R evolves).

See Also

`is.primitive` showing that primitive functions come in two types (`typeof`), `.Internal`.

Examples

```
mysqrt <- .Primitive("sqrt")
try(structure(mysqrt, comment = "primitive function")) # no more possible
c
.Internal # this one must be primitive!
`if` # need backticks
```

print

Print Values

Description

`print` prints its argument and returns it *invisibly* (via `invisible(x)`). It is a generic function which means that new printing methods can be easily added for new `classes`.

Usage

```
print(x, ...)

## S3 method for class 'factor'
print(x, quote = FALSE, max.levels = NULL,
      width = getOption("width"), ...)

## S3 method for class 'table'
print(x, digits = getOption("digits"), quote = FALSE,
      na.print = "", zero.print = "0",
      right = is.numeric(x) || is.complex(x),
      justify = "none", ...)

## S3 method for class 'function'
print(x, useSource = TRUE, ...)
```

Arguments

<code>x</code>	an object used to select a method.
<code>...</code>	further arguments passed to or from other methods.
<code>quote</code>	logical, indicating whether or not strings should be printed with surrounding quotes.
<code>max.levels</code>	integer, indicating how many levels should be printed for a factor; if 0, no extra "Levels" line will be printed. The default, <code>NULL</code> , entails choosing <code>max.levels</code> such that the levels print on one line of width <code>width</code> .
<code>width</code>	only used when <code>max.levels</code> is <code>NULL</code> , see above.
<code>digits</code>	minimal number of <i>significant</i> digits, see <code>print.default</code> .
<code>na.print</code>	character string (or <code>NULL</code>) indicating <code>NA</code> values in printed output, see <code>print.default</code> .
<code>zero.print</code>	character specifying how zeros (0) should be printed; for sparse tables, using <code>"."</code> can produce more readable results, similar to printing sparse matrices in Matrix .
<code>right</code>	logical, indicating whether or not strings should be right aligned.
<code>justify</code>	character indicating if strings should left- or right-justified or left alone, passed to <code>format</code> .
<code>useSource</code>	logical indicating if internally stored source should be used for printing when present, e.g., if <code>options(keep.source = TRUE)</code> has been in use.

Details

The default method, `print.default` has its own help page. Use `methods("print")` to get all the methods for the `print` generic.

`print.factor` allows some customization and is used for printing `ordered` factors as well.

`print.table` for printing `tables` allows other customization. As of R 3.0.0, it only prints a description in case of a table with 0-extents (this can happen if a classifier has no valid data).

See `noquote` as an example of a class whose main purpose is a specific `print` method.

See Also

The default method `print.default`, and help for the methods above; further `options`, `noquote`.

For more customizable (but cumbersome) printing, see `cat`, `format` or also `write`. For a simple prototypical print method, see `.print.via.format` in package `tools`.

Examples

```
require(stats)

ts(1:20)  #-- print is the "Default function" --> print.ts(.) is called
for(i in 1:3) print(1:i)

## Printing of factors
attenu$station ## 117 levels -> 'max.levels' depending on width

## ordered factors: levels  "l1 < l2 < .."
esoph$agegp[1:12]
esoph$alcgp[1:12]

## Printing of sparse (contingency) tables
set.seed(521)
t1 <- round(abs(rt(200, df = 1.8)))
t2 <- round(abs(rt(200, df = 1.4)))
table(t1, t2) # simple
print(table(t1, t2), zero.print = ".") # nicer to read

## same for non-integer "table":
T <- table(t2, t1)
T <- T * (1+round(rlnorm(length(T)))/4)
print(T, zero.print = ".") # quite nicer,
print.table(T[,2:8] * 1e9, digits=3, zero.print = ".")
## still slightly inferior to Matrix::Matrix(T) for larger T

## Corner cases with empty extents:
table(1, NA) # < table of extent 1 x 0 >
```

print.data.frame *Printing Data Frames*

Description

Print a data frame.

Usage

```
## S3 method for class 'data.frame'
print(x, ..., digits = NULL,
      quote = FALSE, right = TRUE, row.names = TRUE, max = NULL)
```

Arguments

x	object of class <code>data.frame</code> .
...	optional arguments to print methods.
digits	the minimum number of significant digits to be used: see print.default .
quote	logical, indicating whether or not entries should be printed with surrounding quotes.
right	logical, indicating whether or not strings should be right-aligned. The default is right-alignment.
row.names	logical (or character vector), indicating whether (or what) row names should be printed.
max	numeric or <code>NULL</code> , specifying the maximal number of entries to be printed. By default, when <code>NULL</code> , getOption("max.print") used.

Details

This calls [format](#) which formats the data frame column-by-column, then converts to a character matrix and dispatches to the `print` method for matrices.

When `quote = TRUE` only the entries are quoted not the row names nor the column names.

See Also

[data.frame](#).

Examples

```
(dd <- data.frame(x = 1:8, f = gl(2,4), ch = letters[1:8]))
# print() with defaults
print(dd, quote = TRUE, row.names = FALSE)
# suppresses row.names and quotes all entries
```

print.default	Default Printing
---------------	------------------

Description

`print.default` is the *default* method of the generic `print` function which prints its argument.

Usage

```
## Default S3 method:
print(x, digits = NULL, quote = TRUE,
      na.print = NULL, print.gap = NULL, right = FALSE,
      max = NULL, width = NULL, useSource = TRUE, ...)
```

Arguments

<code>x</code>	the object to be printed.
<code>digits</code>	a non-null value for <code>digits</code> specifies the minimum number of significant digits to be printed in values. The default, <code>NULL</code> , uses <code>getOption("digits")</code> . (For the interpretation for complex numbers see signif .) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.
<code>quote</code>	logical, indicating whether or not strings (characters) should be printed with surrounding quotes.
<code>na.print</code>	a character string which is used to indicate <code>NA</code> values in printed output, or <code>NULL</code> (see ‘Details’).
<code>print.gap</code>	a non-negative integer ≤ 1024 , or <code>NULL</code> (meaning 1), giving the spacing between adjacent columns in printed vectors, matrices and arrays.
<code>right</code>	logical, indicating whether or not strings should be right aligned. The default is left alignment.
<code>max</code>	a non-null value for <code>max</code> specifies the approximate maximum number of entries to be printed. The default, <code>NULL</code> , uses <code>getOption("max.print")</code> : see that help page for more details.
<code>width</code>	controls the maximum number of columns on a line used in printing vectors, matrices, etc. The default, <code>NULL</code> , uses <code>getOption("width")</code> : see that help page for more details including allowed values.
<code>useSource</code>	logical, indicating whether to use source references or copies rather than deparsing language objects . The default is to use the original source if it is available.
<code>...</code>	further arguments to be passed to or from other methods. They are ignored in this function.

Details

The default for printing `NA`s is to print `NA` (without quotes) unless this is a character `NA` *and* `quote = FALSE`, when ‘<NA>’ is printed. When `na.print` is not `NULL`, it handles how character `NA` is displayed, with no interaction with `quote`.

The same number of decimal places is used throughout a vector. This means that `digits` specifies the minimum number of significant digits to be used, and that at least one entry will be encoded

with that minimum number. However, if all the encoded elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Decimal points are only included if at least one decimal place is selected.

You can suppress “exponential”/scientific notation in printing of numbers (atomic vectors `x`), via `format(., scientific=FALSE)`, see the `prI()` example below, or also by increasing global option `scipen`, e.g., `options(scipen = 12)`.

Attributes are printed respecting their class(es), using the values of `digits` to `print.default`, but using the default values (for the methods called) of the other arguments.

Option `width` controls the printing of vectors, matrices and arrays, and option `deparse.cutoff` controls the printing of [language objects](#) such as calls and formulae.

When the **methods** package is attached, `print` will call `show` for R objects with formal classes (`'S4'`) if called with no optional arguments.

Large number of digits

Note that for large values of `digits`, currently for `digits >= 16`, the calculation of the number of significant digits will depend on the platform’s internal (C library) implementation of `'sprintf()'` functionality.

Single-byte locales

If a non-printable character is encountered during output, it is represented as one of the ANSI escape sequences (`'\a'`, `'\b'`, `'\f'`, `'\n'`, `'\r'`, `'\t'`, `'\v'`, `'\\'` and `'\0'`: see [Quotes](#)), or failing that as a 3-digit octal code: for example the UK currency pound sign in the C locale (if implemented correctly) is printed as `'\243'`. Which characters are non-printable depends on the locale. (Because some versions of Windows get this wrong, all bytes with the upper bit set are regarded as printable on Windows in a single-byte locale.)

Unicode and other multi-byte locales

In all locales, the characters in the ASCII range (`'0x00'` to `'0x7f'`) are printed in the same way, as-is if printable, otherwise via ANSI escape sequences or 3-digit octal escapes as described for single-byte locales. Whether a character is printable depends on the current locale and the operating system (C library).

Multi-byte non-printing characters are printed as an escape sequence of the form `'\uxxxx'` or `'\Uxxxxxxxx'` (in hexadecimal). This is the internal code for the wide-character representation of the character. If this is not known to be Unicode code points, a warning is issued. The only known exceptions are certain Japanese ISO 2022 locales on commercial Unixes, which use a concatenation of the bytes: it is unlikely that R compiles on such a system.

It is possible to have a character string in a character vector that is not valid in the current locale. If a byte is encountered that is not part of a valid character it is printed in hex in the form `'\xab'` and this is repeated until the start of a valid character. (This will rapidly recover from minor errors in UTF-8.)

See Also

The generic `print`, `options`. The `"noquote"` class and `print` method.
`encodeString`, which encodes a character vector the way it would be printed.

Examples

```
pi
print(pi, digits = 16)
LETTERS[1:16]
print(LETTERS, quote = FALSE)

M <- cbind(I = 1, matrix(1:10000, ncol = 10,
                        dimnames = list(NULL, LETTERS[1:10])))
utils::head(M)          # makes more sense than
print(M, max = 1000)    # prints 90 rows and a message about omitting 910

(x <- 2^seq(-8, 30, by=1/4)) # auto-prints; by default all in "exponential" format
prI <- function(x) noquote(format(x, scientific = FALSE))
prI(x) # prints more "nicely" (using a bit more space)
```

prmatrix	<i>Print Matrices, Old-style</i>
----------	----------------------------------

Description

An earlier method for printing matrices, provided for S compatibility.

Usage

```
prmatrix(x, rowlab =, collab =,
         quote = TRUE, right = FALSE, na.print = NULL, ...)
```

Arguments

x	numeric or character matrix.
rowlab, collab	(optional) character vectors giving row or column names respectively. By default, these are taken from <code>dimnames(x)</code> .
quote	logical; if TRUE and x is of mode "character", <i>quotes</i> (‘”’) are used.
right	if TRUE and x is of mode "character", the output columns are <i>right-justified</i> .
na.print	how NAs are printed. If this is non-null, its value is used to represent NA.
...	arguments for print methods.

Details

`prmatrix` is an earlier form of `print.matrix`, and is very similar to the S function of the same name.

Value

Invisibly returns its argument, x.

See Also

`print.default`, and other `print` methods.

Examples

```
prmatrix(m6 <- diag(6), rowlab = rep("", 6), collab = rep("", 6))

chm <- matrix(scan(system.file("help", "AnIndex", package = "splines"),
                           what = ""), , 2, byrow = TRUE)
chm # uses print.matrix()
prmatrix(chm, collab = paste("Column", 1:3), right = TRUE, quote = FALSE)
```

proc.time

Running Time of R

Description

`proc.time` determines how much real and CPU time (in seconds) the currently running R process has already taken.

Usage

```
proc.time()
```

Details

`proc.time` returns five elements for backwards compatibility, but its `print` method prints a named vector of length 3. The first two entries are the total user and system CPU times of the current R process and any child processes on which it has waited, and the third entry is the ‘real’ elapsed time since the process was started.

Value

An object of class `"proc_time"` which is a numeric vector of length 5, containing the user, system, and total elapsed times for the currently running R process, and the cumulative sum of user and system times of any child processes spawned by it on which it has waited. (The `print` method uses the `summary` method to combine the child times with those of the main process.)

The definition of ‘user’ and ‘system’ times is from your OS. Typically it is something like

The ‘user time’ is the CPU time charged for the execution of user instructions of the calling process. The ‘system time’ is the CPU time charged for execution by the system on behalf of the calling process.

Times of child processes are not available on Windows and will always be given as NA.

The resolution of the times will be system-specific and on Unix-alikes times are rounded down to milliseconds. On modern systems they will be that accurate, but in the 20th century they might have been accurate to 1/100 or 1/60 sec. They are typically available to 10ms on Windows.

This is a [primitive](#) function.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[system.time](#) for timing an R expression, [gc.time](#) for how much of the time was spent in garbage collection.

[setTimeLimit](#) to *limit* the CPU or elapsed time for the session or an expression.

Examples

```
## a way to time an R expression: system.time is preferred
ptm <- proc.time()
for (i in 1:50) mad(stats::runif(500))
proc.time() - ptm
```

prod	<i>Product of Vector Elements</i>
------	-----------------------------------

Description

`prod` returns the product of all the values present in its arguments.

Usage

```
prod(..., na.rm = FALSE)
```

Arguments

<code>...</code>	numeric or complex or logical vectors.
<code>na.rm</code>	logical (TRUE or FALSE). Should missing values be removed?

Details

If `na.rm` is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Logical true values are regarded as one, false values as zero. For historical reasons, NULL is accepted and treated as if it were `numeric(0)`.

Value

The product, a numeric (of type "double") or complex vector of length one. **NB:** the product of an empty set is one, by definition.

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Examples

```
print(prod(1:7)) == print(gamma(8))
```

proportions	<i>Express Table Entries as Fraction of Marginal Table</i>
-------------	--

Description

Returns conditional proportions given margins, i.e., entries of `x`, divided by the appropriate marginal sums.

Usage

```
proportions(x, margin = NULL)
prop.table(x, margin = NULL)
```

Arguments

<code>x</code>	an array, usually a table .
<code>margin</code>	a vector giving the margins to split by. E.g., for a matrix 1 indicates rows, 2 indicates columns, <code>c(1, 2)</code> indicates rows and columns. When <code>x</code> has named dimnames , it can be a character vector selecting dimension names.

Value

A table or array like `x`, expressed relative to `margin`.

Note

`prop.table` is an earlier name, retained for back-compatibility.

Author(s)

Peter Dalgaard

See Also

[marginSums](#).

[apply](#) and [sweep](#) are more general mechanisms for sweeping out marginal statistics.

Examples

```

m <- matrix(1:4, 2)
m
proportions(m, 1)

DF <- as.data.frame(UCBAdmissions)
tbl <- xtabs(Freq ~ Gender + Admit, DF)
tbl
proportions(tbl, "Gender")

```

pushBack

*Push Text Back on to a Connection***Description**

Functions to push back text lines onto a [connection](#), and to enquire how many lines are currently pushed back.

Usage

```

pushBack(data, connection, newLine = TRUE,
          encoding = c("", "bytes", "UTF-8"))
pushBackLength(connection)
clearPushBack(connection)

```

Arguments

<code>data</code>	a character vector.
<code>connection</code>	a connection .
<code>newLine</code>	logical. If true, a newline is appended to each string pushed back.
<code>encoding</code>	character string, partially matched. See details.

Details

Several character strings can be pushed back on one or more occasions. The occasions form a stack, so the first line to be retrieved will be the first string from the last call to `pushBack`. Lines which are pushed back are read prior to the normal input from the connection, by the normal text-reading functions such as [readLines](#) and [scan](#).

Pushback is only allowed for readable connections in text mode.

Not all uses of connections respect pushbacks, in particular the input connection is still wired directly, so for example parsing commands from the console and `scan("")` ignore pushbacks on `stdin`.

When character strings with a marked encoding (see [Encoding](#)) are pushed back they are converted to the current encoding if `encoding = ""`. This may involve representing characters as `'<U+xxxx>'` if they cannot be converted. They will be converted to UTF-8 if `encoding = "UTF-8"` or left as-is if `encoding = "bytes"`.

Value

`pushBack` and `clearPushBack()` return nothing, invisibly.
`pushBackLength` returns the number of lines currently pushed back.

See Also

[connections](#), [readLines](#).

Examples

```
zz <- textConnection(LETTERS)
readLines(zz, 2)
pushBack(c("aa", "bb"), zz)
pushBackLength(zz)
readLines(zz, 1)
pushBackLength(zz)
readLines(zz, 1)
readLines(zz, 1)
close(zz)
```

qr

The QR Decomposition of a Matrix

Description

qr computes the QR decomposition of a matrix.

Usage

```
qr(x, ...)
## Default S3 method:
qr(x, tol = 1e-07 , LAPACK = FALSE, ...)

qr.coef(qr, y)
qr.qy(qr, y)
qr.qty(qr, y)
qr.resid(qr, y)
qr.fitted(qr, y, k = qr$rank)
qr.solve(a, b, tol = 1e-7)
## S3 method for class 'qr'
solve(a, b, ...)

is.qr(x)
as.qr(x)
```

Arguments

x	a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
tol	the tolerance for detecting linear dependencies in the columns of x. Only used if LAPACK is false and x is real.
qr	a QR decomposition of the type computed by qr.
y, b	a vector or matrix of right-hand sides of equations.
a	a QR decomposition or (qr.solve only) a rectangular matrix.
k	effective rank.
LAPACK	logical. For real x, if true use LAPACK otherwise use LINPACK (the default).
...	further arguments passed to or from other methods.

Details

The QR decomposition plays an important role in many statistical techniques. In particular it can be used to solve the equation $Ax = b$ for given matrix A , and vector b . It is useful for computing regression coefficients and in applying the Newton-Raphson algorithm.

The functions `qr.coef`, `qr.resid`, and `qr.fitted` return the coefficients, residuals and fitted values obtained when fitting y to the matrix with QR decomposition `qr`. (If pivoting is used, some of the coefficients will be NA.) `qr.qy` and `qr.qty` return $Q \%*\% y$ and $t(Q) \%*\% y$, where Q is the (complete) Q matrix.

All the above functions keep `dimnames` (and `names`) of x and y if there are any.

`solve.qr` is the method for `solve` for `qr` objects. `qr.solve` solves systems of equations via the QR decomposition: if a is a QR decomposition it is the same as `solve.qr`, but if a is a rectangular matrix the QR decomposition is computed first. Either will handle over- and under-determined systems, providing a least-squares fit if appropriate.

`is.qr` returns TRUE if x is a `list` and `inherits` from "qr".

It is not possible to coerce objects to mode "qr". Objects either are QR decompositions or they are not.

The LINPACK interface is restricted to matrices x with less than 2^{31} elements.

`qr.fitted` and `qr.resid` only support the LINPACK interface.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The QR decomposition of the matrix as computed by LINPACK(*) or LAPACK. The components in the returned value correspond directly to the values returned by DQRDC(2)/DGEQP3/ZGEQP3.

<code>qr</code>	a matrix with the same dimensions as x . The upper triangle contains the R of the decomposition and the lower triangle contains information on the Q of the decomposition (stored in compact form). Note that the storage used by DQRDC (LINPACK) and DGEQP3 (LAPACK) differs.
<code>qraux</code>	a vector of length <code>ncol(x)</code> in the LINPACK case and <code>min(dim(x))</code> in the LAPACK case, which contains additional information on Q .
<code>rank</code>	the rank of x as computed by the decomposition(*): always full rank in the LAPACK case.
<code>pivot</code>	information on the pivoting strategy used during the decomposition.

Non-complex QR objects computed by LAPACK have the attribute "useLAPACK" with value TRUE.

*) dqrdc2 instead of LINPACK's DQRDC

In the (default) LINPACK case (`LAPACK = FALSE`), `qr()` uses a *modified* version of LINPACK's DQRDC, called 'dqrdc2'. It differs by using the tolerance `tol` for a pivoting strategy which moves columns with near-zero 2-norm to the right-hand edge of the x matrix. This strategy means that sequential one degree-of-freedom effects can be computed in a natural way.

Note

To compute the determinant of a matrix (do you *really* need it?), the QR decomposition is much more efficient than using eigenvalues ([eigen](#)). See [det](#).

Using LAPACK (including in the complex case) uses column pivoting and does not attempt to detect rank-deficient matrices.

Source

For `qr`, the LINPACK routine DQRDC (but modified to `dqrdc2(*)`) and the LAPACK routines DGEQP3 and ZGEQP3. Further LINPACK and LAPACK routines are used for `qr.coef`, `qr.qy` and `qr.qty`.

LAPACK and LINPACK are from <https://netlib.org/lapack/> and <https://netlib.org/linpack/> and their guides are listed in the references.

Examples

```
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, `+`) }
h9 <- hilbert(9); h9
qr(h9)$rank           #--> only 7
qrh9 <- qr(h9, tol = 1e-10)
qrh9$rank             #--> 9
##-- Solve linear equation system H %*% x = y :
y <- 1:9/10
x <- qr.solve(h9, y, tol = 1e-10) # or equivalently :
x <- qr.coef(qrh9, y) #-- is == but much better than
                        #-- solve(h9) %*% y
h9 %*% x              # = y

## overdetermined system
A <- matrix(runif(12), 4)
b <- 1:4
qr.solve(A, b) # or solve(qr(A), b)
solve(qr(A, LAPACK = TRUE), b)
# this is a least-squares solution, cf. lm(b ~ 0 + A)
```

```
## underdetermined system
A <- matrix(runif(12), 3)
b <- 1:3
qr.solve(A, b)
solve(qr(A, LAPACK = TRUE), b)
# solutions will have one zero, not necessarily the same one
```

QR.Auxiliaries

*Reconstruct the Q, R, or X Matrices from a QR Object***Description**

Returns the original matrix from which the object was constructed or the components of the decomposition.

Usage

```
qr.X(qr, complete = FALSE, ncol =)
qr.Q(qr, complete = FALSE, Dvec =)
qr.R(qr, complete = FALSE)
```

Arguments

<code>qr</code>	object representing a QR decomposition. This will typically have come from a previous call to <code>qr</code> or <code>lsfit</code> .
<code>complete</code>	logical expression of length 1. Indicates whether an arbitrary orthogonal completion of the Q or X matrices is to be made, or whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.
<code>ncol</code>	integer in the range <code>1:nrow(qr\$qr)</code> . The number of columns to be in the reconstructed X . The default when <code>complete</code> is <code>FALSE</code> is the first <code>min(ncol(X), nrow(X))</code> columns of the original X from which the <code>qr</code> object was constructed. The default when <code>complete</code> is <code>TRUE</code> is a square matrix with the original X in the first <code>ncol(X)</code> columns and an arbitrary orthogonal completion (unitary completion in the complex case) in the remaining columns.
<code>Dvec</code>	vector (not matrix) of diagonal values. Each column of the returned Q will be multiplied by the corresponding diagonal value. Defaults to all 1s.

Value

`qr.X` returns **X**, the original matrix from which the `qr` object was constructed, provided `ncol(X) <= nrow(X)`. If `complete` is `TRUE` or the argument `ncol` is greater than `ncol(X)`, additional columns from an arbitrary orthogonal (unitary) completion of **X** are returned.

`qr.Q` returns part or all of **Q**, the orthogonal (unitary) transformation of order `nrow(X)` represented by `qr`. If `complete` is `TRUE`, **Q** has `nrow(X)` columns. If `complete` is `FALSE`, **Q** has `ncol(X)` columns. When `Dvec` is specified, each column of **Q** is multiplied by the corresponding value in `Dvec`.

Note that `qr.Q(qr, *)` is a special case of `qr.qy(qr, y)` (with a “diagonal” `y`), and `qr.X(qr, *)` is basically `qr.qy(qr, R)` (apart from pivoting and `dimnames` setting).

`qr.R` returns **R**. This may be pivoted, e.g., if `a <- qr(x)` then `x[, a$pivot] = QR`. The number of rows of **R** is either `nrow(X)` or `ncol(X)` (and may depend on whether `complete` is `TRUE` or `FALSE`).

See Also

`qr`, `qr.qy`.

Examples

```
p <- ncol(x <- LifeCycleSavings[, -1]) # not the 'sr'
qrstr <- qr(x) # dim(x) == c(n,p)
qrstr $ rank # = 4 = p
Q <- qr.Q(qrstr) # dim(Q) == dim(x)
R <- qr.R(qrstr) # dim(R) == ncol(x)
X <- qr.X(qrstr) # X == x
range(X - as.matrix(x)) # ~ < 6e-12
## X == Q %*% R if there has been no pivoting, as here:
all.equal(unname(X),
          unname(Q %*% R))

# example of pivoting
x <- cbind(int = 1,
           b1 = rep(1:0, each = 3), b2 = rep(0:1, each = 3),
           c1 = rep(c(1,0,0), 2), c2 = rep(c(0,1,0), 2), c3 = rep(c(0,0,1), 2))
x # is singular, columns "b2" and "c3" are "extra"
a <- qr(x)
zapsmall(qr.R(a)) # columns are int b1 c1 c2 b2 c3
a$pivot
pivI <- sort.list(a$pivot) # the inverse permutation
all.equal(x, qr.Q(a) %*% qr.R(a)) # no, no
stopifnot(
  all.equal(x[, a$pivot], qr.Q(a) %*% qr.R(a)), # TRUE
  all.equal(x, qr.Q(a) %*% qr.R(a)[, pivI])) # TRUE too!
```

quit

Terminate an R Session

Description

The function `quit` or its alias `q` terminate the current R session.

Usage

```
quit(save = "default", status = 0, runLast = TRUE)
q(save = "default", status = 0, runLast = TRUE)
```

Arguments

<code>save</code>	a character string indicating whether the environment (workspace) should be saved, one of "no", "yes", "ask" or "default".
<code>status</code>	the (numerical) error status to be returned to the operating system, where relevant. Conventionally 0 indicates successful completion.
<code>runLast</code>	should <code>.Last()</code> be executed?

Details

`save` must be one of "no", "yes", "ask" or "default". In the first case the workspace is not saved, in the second it is saved and in the third the user is prompted and can also decide *not* to quit. The default is to ask in interactive use but may be overridden by command-line arguments (which must be supplied in non-interactive use).

Immediately *before* normal termination, `.Last()` is executed if the function `.Last` exists and `runLast` is true. If in interactive use there are errors in the `.Last` function, control will be returned to the command prompt, so do test the function thoroughly. There is a system analogue, `.Last.sys()`, which is run after `.Last()` if `runLast` is true.

Exactly what happens at termination of an R session depends on the platform and GUI interface in use. A typical sequence is to run `.Last()` and `.Last.sys()` (unless `runLast` is false), to save the workspace if requested (and in most cases also to save the session history: see [savehistory](#)), then run any finalizers (see [reg.finalizer](#)) that have been set to be run on exit, close all open graphics devices, remove the session temporary directory and print any remaining warnings (e.g., from `.Last()` and device closure).

Some error status values are used by R itself. The default error handler for non-interactive use effectively calls `q("no", 1, FALSE)` and returns error status 1. Error status 2 is used for R 'suicide', that is a catastrophic failure, and other small numbers are used by specific ports for initialization failures. It is recommended that users choose statuses of 10 or more.

Valid values of `status` are system-dependent, but 0:255 are normally valid. (Many OSes will report the last byte of the value, that is report the value modulo 256. But not all.)

Warning

The value of `.Last` is for the end user to control: as it can be replaced later in the session, it cannot safely be used programmatically, e.g. by a package. The other way to set code to be run at the end of the session is to use a *finalizer*: see [reg.finalizer](#).

Note

The R.app GUI on macOS has its own version of these functions with slightly different behaviour for the `save` argument (the GUI's 'Startup' preferences for this action are taken into account).

See Also

[.First](#) for setting things on startup.

Examples

```
## Not run: ## Unix-flavour example
.Last <- function() {
  graphics.off() # close devices before printing
  cat("Now sending PDF graphics to the printer:\n")
  system("lpr Rplots.pdf")
  cat("bye bye...\n")
}
quit("yes")
## End(Not run)
```

 Quotes

Quotes

Description

Descriptions of the various uses of quoting in R.

Details

Three types of quotes are part of the syntax of R: single and double quotation marks and the backtick (or back quote, ‘`’). In addition, backslash is used to escape the following character inside character constants.

Character constants

Single and double quotes delimit character constants. They can be used interchangeably but double quotes are preferred (and character constants are printed using double quotes), so single quotes are normally only used to delimit character constants containing double quotes.

Backslash is used to start an escape sequence inside character constants. Escaping a character not in the following table is an error.

Single quotes need to be escaped by backslash in single-quoted strings, and double quotes in double-quoted strings.

<code>‘\n’</code>	newline (aka ‘line feed’)
<code>‘\r’</code>	carriage return
<code>‘\t’</code>	tab
<code>‘\b’</code>	backspace
<code>‘\a’</code>	alert (bell)
<code>‘\f’</code>	form feed
<code>‘\v’</code>	vertical tab
<code>‘\\’</code>	backslash ‘\’
<code>‘\’</code>	ASCII apostrophe ‘’
<code>‘\”</code>	ASCII quotation mark ‘”’
<code>‘\`’</code>	ASCII grave accent (backtick) ‘`’
<code>‘\nnn’</code>	character with given octal code (1, 2 or 3 digits)
<code>‘\xnn’</code>	character with given hex code (1 or 2 hex digits)
<code>‘\unnnn’</code>	Unicode character with given code (1–4 hex digits)
<code>‘\Unnnnnnnn’</code>	Unicode character with given code (1–8 hex digits)

Alternative forms for the last two are `‘\u{nnnn}’` and `‘\U{nnnnnnnn}’`. All except the Unicode escape sequences are also supported when reading character strings by `scan` and `read.table` if `allowEscapes = TRUE`. Unicode escapes can be used to enter Unicode characters not in the current locale’s charset (when the string will be stored internally in UTF-8). The maximum allowed value for `‘\nnn’` is `‘\377’` (the same character as `‘\xff’`).

As from R 4.1.0 the largest allowed `‘\U’` value is `‘\U10FFFF’`, the maximum Unicode point.

The parser does not allow the use of both octal/hex and Unicode escapes in a single string.

These forms will also be used by `print.default` when outputting non-printable characters (including backslash).

Embedded NULs are not allowed in character strings, so using escapes (such as `'\0'`) for a NUL will result in the string being truncated at that point (usually with a warning).

Raw character constants are also available using a syntax similar to the one used in C++: `Ⓡ" ( . . . ) "` with `. . .` any character sequence, except that it must not contain the closing sequence `' ) '`. The delimiter pairs `[]` and `{ }` can also be used, and `Ⓡ` can be used in place of `Ⓡ`. For additional flexibility, a number of dashes can be placed between the opening quote and the opening delimiter, as long as the same number of dashes appear between the closing delimiter and the closing quote.

Names and Identifiers

Identifiers consist of a sequence of letters, digits, the period (`.`) and the underscore. They must not start with a digit nor underscore, nor with a period followed by a digit. [Reserved](#) words are not valid identifiers.

The definition of a *letter* depends on the current locale, but only ASCII digits are considered to be digits.

Such identifiers are also known as *syntactic names* and may be used directly in R code. Almost always, other names can be used provided they are quoted. The preferred quote is the backtick (```), and [deparse](#) will normally use it, but under many circumstances single or double quotes can be used (as a character constant will often be converted to a name). One place where backticks may be essential is to delimit variable names in formulae: see [formula](#).

Note

UTF-16 surrogate pairs in `'\unnnn\uoooo'` form will be converted to a single Unicode point, so for example `'\uD834\uDD1E'` gives the single character `'\U1D11E'`. However, unpaired values in the surrogate range such as in the string `"abc\uD834de"` will be converted to a non-standard-conformant UTF-8 string (as is done by most other software): this may change in future.

See Also

[Syntax](#) for other aspects of the syntax.

[sQuote](#) for quoting English text.

[shQuote](#) for quoting OS commands.

Section [“Tokens”](#) in *The R Language Definition*.

Examples

```
'single quotes can be used more-or-less interchangeably'
"with double quotes to create character vectors"

## Single quotes inside single-quoted strings need backslash-escaping.
## Ditto double quotes inside double-quoted strings.
##
identical('"It\'s alive!", he screamed.',
          "\"It's alive!\", he screamed.") # same

## Backslashes need doubling, or they have a special meaning.
x <- "In ALGOL, you could do logical AND with /\\"
print(x)      # shows it as above ("input-like")
writeLines(x) # shows it as you like it ;- )

## Single backslashes followed by a letter are used to denote
```

```

## special characters like tab(ulator)s and newlines:
x <- "long\tlines can be\nbroken with newlines"
writeLines(x) # see also ?strwrap

## Backticks are used for non-standard variable names.
## (See make.names and ?Reserved for what counts as
## non-standard.)
`x` `y` <- 1:5
`x` `y`
d <- data.frame(`1st column` = rchisq(5, 2), check.names = FALSE)
d$`1st column`

## Backslashes followed by up to three numbers are interpreted as
## octal notation for ASCII characters.
"\110\145\154\154\157\40\127\157\162\154\144\41"

## \x followed by up to two numbers is interpreted as
## hexadecimal notation for ASCII characters.
(hw1 <- "\x48\x65\x6c\x6c\x6f\x20\x57\x6f\x72\x6c\x64\x21")

## Mixing octal and hexadecimal in the same string is OK
(hw2 <- "\110\x65\154\x6c\157\x20\127\x6f\162\x6c\144\x21")

## \u is also hexadecimal, but supports up to 4 digits,
## using Unicode specification. In the previous example,
## you can simply replace \x with \u.
(hw3 <- "\u48\u65\u6c\u6c\u6f\u20\u57\u6f\u72\u6c\u64\u21")

## The last three are all identical to
hw <- "Hello World!"
stopifnot(identical(hw, hw1), identical(hw1, hw2), identical(hw2, hw3))

## Using Unicode makes more sense for non-latin characters.
(nn <- "\u0126\u0119\u1114\u022d\u2001\u03e2\u0954\u0f3f\u13d3\u147b\u203c")

## Mixing \x and \u throws a _parse_ error (which is not catchable!)
## Not run:
  "\x48\u65\x6c\u6c\x6f\u20\x57\u6f\x72\u6c\x64\u21"

## End(Not run)
## --> Error: mixing Unicode and octal/hex escapes .....

## \U works like \u, but supports up to six hex digits.
## So we can replace \u with \U in the previous example.
n2 <- "\U0126\U0119\U1114\U022d\U2001\U03e2\U0954\U0f3f\U13d3\U147b\U203c"
stopifnot(identical(nn, n2))

## Under systems supporting multi-byte locales (and not Windows),
## \U also supports the rarer characters outside the usual 16^4 range.
## See the R language manual, RShowDoc("R-lang#Literal-constants"),
## and PR#16098 <https://bugs.r-project.org/show\_bug.cgi?id=16098>.
## This character may or not be printable (the platform decides)
## and if it is, may not have a glyph in the font used.
"\U1d4d7" # On Windows this used to give the incorrect value of "\Ud4d7"

## nul characters (for terminating strings in C) are not allowed (parse errors)
## Not run:

```

```

"foo\0bar"      # Error: nul character not allowed (line 1)
"foo\u0000bar" # same error

## End(Not run)

## A Windows path written as a raw string constant:
r"(c:\Program files\R) "

## More raw strings:
r"{(\1\2)}"
r"(use both "double" and 'single' quotes)"
r"---(\1--)-"

```

R.Version	<i>Version Information</i>
-----------	----------------------------

Description

`R.Version()` provides detailed information about the version of R running.

`R.version` is a variable (a [list](#)) holding this information (and `version` is a copy of it for S compatibility).

Usage

```

R.Version()
R.version
R.version.string
version

R_compiled_by()

```

Details

This gives details of the OS under which R was built, not the one under which it is currently running (for which see [Sys.info](#)).

Note that OS names might not be what you expect: for example macOS Mavericks 10.9.4 identifies itself as ‘darwin13.3.0’, Linux usually as ‘linux-gnu’, Solaris 10 as ‘solaris2.10’ and Windows as ‘mingw32’.

`R.version$cert` is supported on Windows since R 4.2.0 and returns "ucrt" to denote the Universal C Runtime. It would return "msvcrt" for the older Microsoft Visual C++ Runtime (but R does not use that runtime since 4.2.0).

Value

`R.Version` returns a list with character-string components

<code>platform</code>	the platform for which R was built. A triplet of the form CPU-VENDOR-OS, as determined by the configure script. E.g, "i686-unknown-linux-gnu" or "i386-pc-mingw32".
<code>arch</code>	the architecture (CPU) R was built on/for.
<code>os</code>	the underlying operating system.

<code>crt</code>	the C runtime on Windows.
<code>system</code>	CPU and OS, separated by a comma.
<code>status</code>	the status of the version (e.g., "alpha").
<code>major</code>	the major version number.
<code>minor</code>	the minor version number, including the patch level.
<code>year</code>	the year the version was released.
<code>month</code>	the month the version was released.
<code>day</code>	the day the version was released.
<code>svn rev</code>	the Subversion revision number, which should be either "unknown" or a single number. (A range of numbers or a number with 'M' or 'S' appended indicates inconsistencies in the sources used to build this version of R.)
<code>language</code>	always "R".
<code>version.string</code>	a character string concatenating some of the info above, useful for plotting, etc.

`R.version` and `version` are lists of class "simple.list" which has a `print` method.

`R_compiled_by` returns a two-element character vector giving details of the C and Fortran compilers used to build R. (Empty strings if no information is available.)

Note

Do *not* use `R.version$os` to test the platform the code is running on: use `.Platform$OS.type` instead. Slightly different versions of the OS may report different values of `R.version$os`, as may different versions of R. Alternatively, `osVersion` typically contains more details about the platform R is running on.

`R.version.string` is a copy of `R.version$version.string` for simplicity and backwards compatibility.

See Also

[sessionInfo](#) which provides additional information; [getRversion](#) typically used inside R code, [osVersion](#), [.Platform](#), [Sys.info](#).

Examples

```
require(graphics)

R.version$os # to check how lucky you are ...
plot(0) # any plot
mtext(R.version.string, side = 1, line = 4, adj = 1) # a useful bottom-right note

## a good way to detect macOS:
if(grepl("^darwin", R.version$os)) message("running on macOS")

## Short R version string, ("space free", useful in file/directory names;
## also fine for unreleased versions of R):
shortRversion <- function() {
  rvs <- R.version.string
  if(grepl("devel", (st <- R.version$status)))
    rvs <- sub(paste0(" ",st," "), "-devel_", rvs, fixed=TRUE)
```

```

    gsub("[()]", "", gsub(" ", "_", sub(" version ", "-", rvs)))
  }
  shortRversion()

```

Random

Random Number Generation

Description

`.Random.seed` is an integer vector, containing the random number generator (RNG) **state** for random number generation in R. It can be saved and restored, but should not be altered by the user.

`RNGkind` is a more friendly interface to query or set the kind of RNG in use.

`RNGversion` can be used to set the random generators as they were in an earlier R version (for reproducibility).

`set.seed` is the recommended way to specify seeds.

Usage

```

.Random.seed <- c(rng.kind, n1, n2, ...)

RNGkind(kind = NULL, normal.kind = NULL, sample.kind = NULL)
RNGversion(vstr)
set.seed(seed, kind = NULL, normal.kind = NULL, sample.kind = NULL)

```

Arguments

<code>kind</code>	character or NULL. If <code>kind</code> is a character string, set R's RNG to the kind desired. Use "default" to return to the R default. See 'Details' for the interpretation of NULL.
<code>normal.kind</code>	character string or NULL. If it is a character string, set the method of Normal generation. Use "default" to return to the R default. NULL makes no change.
<code>sample.kind</code>	character string or NULL. If it is a character string, set the method of discrete uniform generation (used in sample , for instance). Use "default" to return to the R default. NULL makes no change.
<code>seed</code>	a single value, interpreted as an integer, or NULL (see 'Details').
<code>vstr</code>	a character string containing a version number, e.g., "1.6.2". The default RNG configuration of the current R version is used if <code>vstr</code> is greater than the current version.
<code>rng.kind</code>	integer code in 0:k for the above <code>kind</code> .
<code>n1, n2, ...</code>	integers. See the details for how many are required (which depends on <code>rng.kind</code>).

Details

The currently available RNG kinds are given below. `kind` is partially matched to this list. The default is "Mersenne-Twister".

"Wichmann-Hill" The seed, `.Random.seed[-1] == r[1:3]` is an integer vector of length 3, where each `r[i]` is in $1:(p[i] - 1)$, where `p` is the length 3 vector of primes, `p = (30269, 30307, 30323)`. The Wichmann-Hill generator has a cycle length of 6.9536×10^{12} ($= \text{prod}(p-1)/4$, see Wichmann and Hill (1984) which corrects the original article). It exhibits 12 clear failures in the TestU01 Crush suite and 22 in the BigCrush suite (L'Ecuyer and Simard 2007).

"Marsaglia-Multicarry": A *multiply-with-carry* RNG is used, as recommended by George Marsaglia in his post to the mailing list 'sci.stat.math' (Marsaglia 1997). It has a period of more than 2^{60} .

It exhibits 40 clear failures in L'Ecuyer's TestU01 Crush suite. Combined with Ahrens-Dieter or Kinderman-Ramage it exhibits deviations from normality even for univariate distribution generation. See [PR#18168](#) for a discussion.

The seed is two integers (all values allowed).

"Super-Duper": Marsaglia's famous Super-Duper from the 70's. This is the original version which does *not* pass the MTUPLE test of the Diehard battery. It has a period of $\approx 4.6 \times 10^{18}$ for most initial seeds. The seed is two integers (all values allowed for the first seed: the second must be odd).

We use the implementation by Reeds, Hubert, and Abrahams (1982-4).

The two seeds are the Tausworthe and congruence long integers, respectively.

It exhibits 25 clear failures in the TestU01 Crush suite (L'Ecuyer and Simard 2007).

"Mersenne-Twister": From Matsumoto and Nishimura (1998); code updated in 2002. A twisted GFSR with period $2^{19937} - 1$ and equidistribution in 623 consecutive dimensions (over the whole period). The 'seed' is a 624-dimensional set of 32-bit integers plus a current position in that set.

R uses its own initialization method due to B. D. Ripley and is not affected by the initialization issue in the 1998 code of Matsumoto and Nishimura addressed in a 2002 update.

It exhibits 2 clear failures in each of the TestU01 Crush and the BigCrush suite (L'Ecuyer and Simard 2007).

"Knuth-TAOCP-2002": A 32-bit integer GFSR using lagged Fibonacci sequences with subtraction. That is, the recurrence used is

$$X_j = (X_{j-100} - X_{j-37}) \bmod 2^{30}$$

and the 'seed' is the set of the 100 last numbers (actually recorded as 101 numbers, the last being a cyclic shift of the buffer). The period is around 2^{129} .

"Knuth-TAOCP": An earlier version from Knuth (1997).

The 2002 version was not backwards compatible with the earlier version: the initialization of the GFSR from the seed was altered. R did not allow you to choose consecutive seeds, the reported 'weakness', and already scrambled the seeds. Otherwise, the algorithm is identical to Knuth-TAOCP-2002, with the same lagged Fibonacci recurrence formula.

Initialization of this generator is done in interpreted R code and so takes a short but noticeable time.

It exhibits 3 clear failure in the TestU01 Crush suite and 4 clear failures in the BigCrush suite (L'Ecuyer and Simard 2007).

"L'Ecuyer-CMRG": A 'combined multiple-recursive generator' from L'Ecuyer (1999), each element of which is a feedback multiplicative generator with three integer elements: thus the seed is a (signed) integer vector of length 6. The period is around 2^{191} .

The 6 elements of the seed are internally regarded as 32-bit unsigned integers. Neither the first three nor the last three should be all zero, and they are limited to less than 4294967087 and 4294944443 respectively.

This is not particularly interesting of itself, but provides the basis for the multiple streams used in package **parallel**.

It exhibits 6 clear failures in each of the TestU01 Crush and the BigCrush suite (L'Ecuyer and Simard 2007).

"user-supplied": Use a user-supplied generator. See [Random.user](#) for details.

`normal.kind` can be "Kinderman-Ramage", "Buggy Kinderman-Ramage" (not for `set.seed`), "Ahrens-Dieter", "Box-Muller", "Inversion" (the default), or "user-supplied". (For inversion, see the reference in [qnorm](#).) The Kinderman-Ramage generator used in versions prior to 1.7.0 (now called "Buggy") had several approximation errors and should only be used for reproduction of old results. The "Box-Muller" generator is stateful as pairs of normals are generated and returned sequentially. The state is reset whenever it is selected (even if it is the current normal generator) and when `kind` is changed.

`sample.kind` can be "Rounding" or "Rejection", or partial matches to these. The former was the default in versions prior to 3.6.0: it made [sample](#) noticeably non-uniform on large populations, and should only be used for reproduction of old results. See [PR#17494](#) for a discussion.

`set.seed` uses a single integer argument to set as many seeds as are required. It is intended as a simple way to get quite different seeds by specifying small integer arguments, and also as a way to get valid seed sets for the more complicated methods (especially "Mersenne-Twister" and "Knuth-TAOCP"). There is no guarantee that different values of `seed` will seed the RNG differently, although any exceptions would be extremely rare. If called with `seed = NULL` it re-initializes (see 'Note') as if no seed had yet been set.

The use of `kind = NULL`, `normal.kind = NULL` or `sample.kind = NULL` in `RNGkind` or `set.seed` selects the currently-used generator (including that used in the previous session if the workspace has been restored): if no generator has been used it selects "default".

Value

`.Random.seed` is an [integer](#) vector whose first element *codes* the kind of RNG and normal generator. The lowest two decimal digits are in $0:(k-1)$ where k is the number of available RNGs. The hundreds represent the type of normal generator (starting at 0), and the ten thousands represent the type of discrete uniform sampler.

In the underlying C, `.Random.seed[-1]` is unsigned; therefore in R `.Random.seed[-1]` can be negative or perhaps [NA_integer_](#), due to the representation of an unsigned integer by a signed integer.

`RNGkind` returns a three-element character vector of the RNG, normal and sample kinds selected *before* the call, invisibly if either argument is not `NULL`. A type starts a session as the default, and is selected either by a call to `RNGkind` or by setting `.Random.seed` in the workspace. (NB: prior to R 3.6.0 the first two kinds were returned in a two-element character vector.)

`RNGversion` returns the same information as `RNGkind` about the defaults in a specific R version.

`set.seed` returns `NULL`, invisibly.

Note

Initially, there is no seed; a new one is created from the current time and the process ID when one is required. Hence different sessions will give different simulation results, by default. However, the seed might be restored from a previous session if a previously saved workspace is restored.

`.Random.seed` saves the seed set for the uniform random-number generator, at least for the system generators. It does not necessarily save the state of other generators, and in particular does not save the state of the Box–Muller normal generator. If you want to reproduce work later, call `set.seed` (preferably with explicit values for `kind` and `normal.kind`) rather than `set.Random.seed`.

The object `.Random.seed` is only looked for in the user's workspace.

Do not rely on randomness of low-order bits from RNGs. Most of the supplied uniform generators return 32-bit integer values that are converted to doubles, so they take at most 2^{32} distinct values and long runs will return duplicated values (Wichmann-Hill is the exception, and all give at least 30 varying bits.)

```

Random.user

User-supplied Random Number Generation

Description

Function `RNGkind` allows user-coded uniform and normal random number generators to be supplied. The details are given here.

Details

A user-specified uniform RNG is called from entry points in dynamically-loaded compiled code. The user must supply the entry point `user_unif_rand`, which takes no arguments and returns a *pointer to a double*. The example below will show the general pattern. The generator should have at least 25 bits of precision.

Optionally, the user can supply the entry point `user_unif_init`, which is called with an `unsigned int` argument when `RNGkind` (or `set.seed`) is called, and is intended to be used to initialize the user's RNG code. The argument is intended to be used to set the 'seeds'; it is the seed argument to `set.seed` or an essentially random seed if `RNGkind` is called.

If only these functions are supplied, no information about the generator's state is recorded in `.Random.seed`. Optionally, functions `user_unif_nseed` and `user_unif_seedloc` can be supplied which are called with no arguments and should return pointers to the number of seeds and to an integer (specifically, 'Int32') array of seeds. Calls to `GetRNGstate` and `PutRNGstate` will then copy this array to and from `.Random.seed`.

A user-specified normal RNG is specified by a single entry point `user_norm_rand`, which takes no arguments and returns a *pointer to a double*.

Warning

As with all compiled code, mis-specifying these functions can crash R. Do include the `'R_ext/Random.h'` header file for type checking.

Examples

```
## Not run:
## Marsaglia's congruential PRNG
#include <R_ext/Random.h>

static Int32 seed;
static double res;
static int nseed = 1;

double * user_unif_rand(void)
{
    seed = 69069 * seed + 1;
    res = seed * 2.32830643653869e-10;
    return &res;
}

void user_unif_init(Int32 seed_in) { seed = seed_in; }
int * user_unif_nseed(void) { return &nseed; }
int * user_unif_seedloc(void) { return (int *) &seed; }

/* ratio-of-uniforms for normal */
#include <math.h>
static double x;

double * user_norm_rand(void)
{
    double u, v, z;
    do {
        u = unif_rand();
        v = 0.857764 * (2. * unif_rand() - 1);
        x = v/u; z = 0.25 * x * x;
        if (z < 1. - u) break;
        if (z > 0.259/u + 0.35) continue;
    } while (z > -log(u));
    return &x;
}

## Use under Unix:
R CMD SHLIB urand.c
R
> dyn.load("urand.so")
> RNGkind("user")
> runif(10)
> .Random.seed
> RNGkind(, "user")
> rnorm(10)
> RNGkind()
[1] "user-supplied" "user-supplied"

## End(Not run)
```

Description

`range` returns a vector containing the minimum and maximum of all the given arguments.

Usage

```
range(..., na.rm = FALSE)
## Default S3 method:
range(..., na.rm = FALSE, finite = FALSE)
## same for classes 'Date' and 'POSIXct'

.rangeNum(..., na.rm, finite, isNumeric)
```

Arguments

<code>...</code>	any numeric or character objects.
<code>na.rm</code>	logical, indicating if NA's should be omitted.
<code>finite</code>	logical, indicating if all non-finite elements should be omitted.
<code>isNumeric</code>	a function returning TRUE or FALSE when called on <code>c(..., recursive = TRUE)</code> , is.numeric() for the default <code>range()</code> method.

Details

`range` is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

If `na.rm` is FALSE, NA and NaN values in any of the arguments will cause NA values to be returned, otherwise NA values are ignored.

If `finite` is TRUE, the minimum and maximum of all finite values is computed, i.e., `finite = TRUE` *includes* `na.rm = TRUE`.

A special situation occurs when there is no (after omission of NAs) nonempty argument left, see [min](#).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

[min](#), [max](#).

The [extendrange\(\)](#) utility in package **grDevices**.

Examples

```
(r.x <- range(stats::rnorm(100)))
diff(r.x) # the SAMPLE range

x <- c(NA, 1:3, -1:1/0); x
range(x)
range(x, na.rm = TRUE)
range(x, finite = TRUE)
```

rank	<i>Sample Ranks</i>
------	---------------------

Description

Returns the sample ranks of the values in a vector. Ties (i.e., equal values) and missing values can be handled in several ways.

Usage

```
rank(x, na.last = TRUE,
     ties.method = c("average", "first", "last", "random", "max", "min"))
```

Arguments

x	a numeric, complex, character or logical vector.
na.last	a logical or character string controlling the treatment of NAs . If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
ties.method	a character string specifying how ties are treated, see ‘Details’; can be abbreviated.

Details

If all components are different (and no NAs), the ranks are well defined, with values in `seq_along(x)`. With some values equal (called ‘ties’), the argument `ties.method` determines the result at the corresponding indices. The "first" method results in a permutation with increasing values at each index set of ties, and analogously "last" with decreasing values. The "random" method puts these in random order whereas the default, "average", replaces them by their mean, and "max" and "min" replaces them by their maximum and minimum respectively, the latter being the typical sports ranking.

NA values are never considered to be equal: for `na.last = TRUE` and `na.last = FALSE` they are given distinct ranks in the order in which they occur in `x`.

NB: `rank` is not itself generic but `xtfrm` is, and `rank(xtfrm(x), ...)` will have the desired result if there is a `xtfrm` method. Otherwise, `rank` will make use of `==`, `>`, `is.na` and extraction methods for classed objects, possibly rather slowly.

Value

A numeric vector of the same length as `x` with names copied from `x` (unless `na.last = NA`, when missing values are removed). The vector is of integer type unless `x` is a long vector or `ties.method = "average"` when it is of double type (whether or not there are any ties).

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[order](#) and [sort](#); [xtfrm](#), see above.

Examples

```
(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))
x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2)) # ties are averaged

## rank() is "idempotent": rank(rank(x)) == rank(x) :
stopifnot(rank(r1) == r1, rank(r2) == r2)

## ranks without averaging
rank(x2, ties.method= "first") # first occurrence wins
rank(x2, ties.method= "last")  # last occurrence wins
rank(x2, ties.method= "random") # ties broken at random
rank(x2, ties.method= "random") # and again

## keep ties ties, no average
(rma <- rank(x2, ties.method= "max")) # as used classically
(rmi <- rank(x2, ties.method= "min")) # as in Sports
stopifnot(rma + rmi == round(r2 + r2))

## Comparing all tie.methods:
tMeth <- eval(formals(rank)$ties.method)
rx2 <- sapply(tMeth, function(M) rank(x2, ties.method=M))
cbind(x2, rx2)
## ties.method's does not matter w/o ties:
x <- sample(47)
rx <- sapply(tMeth, function(MM) rank(x, ties.method=MM))
stopifnot(all(rx[,1] == rx))
```

rapply

Recursively Apply a Function to a List

Description

`rapply` is a recursive version of [lapply](#) with flexibility in *how* the result is structured (`how = "..."`).

Usage

```
rapply(object, f, classes = "ANY", deflt = NULL,
       how = c("unlist", "replace", "list"), ...)
```

Arguments

object	a list or expression , i.e., “list-like”.
f	a function of one “principal” argument, passing further arguments via . . .
classes	character vector of class names, or "ANY" to match any class.
deflt	the default result (not used if how = "replace").
how	character string partially matching the three possibilities given: see ‘Details’.
. . .	additional arguments passed to the call to f.

Details

This function has two basic modes. If how = "replace", each element of object which is not itself list-like and has a class included in classes is replaced by the result of applying f to the element.

Otherwise, with mode how = "list" or how = "unlist", conceptually object is copied, all non-list elements which have a class included in classes are replaced by the result of applying f to the element and all others are replaced by deflt. Finally, if how = "unlist", unlist(recursive = TRUE) is called on the result.

The semantics differ in detail from [lapply](#): in particular the arguments are evaluated before calling the C code.

Note that rapply() being more recent than lapply() does *not* allow a string (with the name of a function) as argument f, on purpose.

In R 3.5.x and earlier, object was required to be a list, which was *not* the case for its list-like components.

Value

If how = "unlist", a vector, otherwise “list-like” of similar structure as object.

References

Chambers JM (1998). *Programming with Data*. Springer, New York. ISBN 978-0-387-98503-9. (rapply is only described briefly there.)

Examples

```
X <- list(list(a = pi, b = list(c = 1L)), d = "a test")
# the "identity operation":
rapply(X, function(x) x, how = "replace") -> X.; stopifnot(identical(X, X.))
rapply(X, sqrt, classes = "numeric", how = "replace")
rapply(X, deparse, control = "all") # passing extras. argument of deparse()
rapply(X, nchar, classes = "character", deflt = NA_integer_, how = "list")
rapply(X, nchar, classes = "character", deflt = NA_integer_, how = "unlist")
rapply(X, nchar, classes = "character",                      how = "unlist")
rapply(X, log, classes = "numeric", how = "replace", base = 2)

## with expression() / list():
E <- expression(list(a = pi, b = expression(c = C1 * C2)), d = "a test")
```

```

LE <- list(expression(a = pi, b = expression(c = C1 * C2)), d = "a test")
rapply(E, nchar, how="replace") # "expression(c = C1 * C2)" are 23 chars
rapply(E, nchar, classes = "character", deflt = NA_integer_, how = "unlist")
rapply(LE, as.character) # a "pi" | b1 "expression" | b2 "C1 * C2" ..
rapply(LE, nchar)        # (see above)
stopifnot(exprs = {
  identical(E , rapply(E , identity, how = "replace"))
  identical(LE, rapply(LE, identity, how = "replace"))
})

```

raw

Raw Vectors

Description

Creates or tests for objects of type "raw".

Usage

```

raw(length = 0)
as.raw(x)
is.raw(x)

```

Arguments

length	desired length.
x	object to be coerced.

Details

The raw type is intended to hold raw bytes. It is possible to extract subsequences of bytes, and to replace elements (but only by elements of a raw vector). The relational operators (see [Comparison](#), using the numerical order of the byte representation) work, as do the logical operators (see [Logic](#)) with a bitwise interpretation.

A raw vector is printed with each byte separately represented as a pair of hex digits. If you want to see a character representation (with escape sequences for non-printing characters) use [rawToChar](#).

Coercion to raw treats the input values as representing small (decimal) integers, so the input is first coerced to integer, and then values which are outside the range [0 . . . 255] or are NA are set to 0 (the nul byte).

`as.raw` and `is.raw` are [primitive](#) functions.

`as.raw` is a generic function.

Value

`raw` creates a raw vector of the specified length. Each element of the vector is equal to 0. Raw vectors are used to store fixed-length sequences of bytes.

`as.raw` attempts to coerce its argument to be of raw type. The (elementwise) answer will be 0 unless the coercion succeeds (or if the original value successfully coerces to 0).

`is.raw` returns true if and only if `typeof(x) == "raw"`.

See Also

`charToRaw`, `rawShift`, etc.
[&](#) for bitwise operations on raw vectors.

Examples

```
xx <- raw(2)
xx[1] <- as.raw(40)      # NB, not just 40.
xx[2] <- charToRaw("A")
xx      ## 28 41  -- raw prints hexadecimal
dput(xx) ## as.raw(c(0x28, 0x41))
as.integer(xx) ## 40 65

x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE
rawToChar(y)
is.raw(x)
is.raw(y)
stopifnot( charToRaw("\xa3") == as.raw(0xa3) )

isASCII <- function(txt) all(charToRaw(txt) <= as.raw(127))
isASCII(x) # true
isASCII("\xa325.63") # false (in Latin-1, this is an amount in UK pounds)
```

rawConnection	<i>Raw Connections</i>
---------------	------------------------

Description

Input and output raw connections.

Usage

```
rawConnection(object, open = "r")

rawConnectionValue(con)
```

Arguments

object	character or raw vector. A description of the connection. For an input this is an R raw vector object, and for an output connection the name for the connection.
open	character. Any of the standard connection open modes.
con	an output raw connection.

Details

An input raw connection is opened and the raw vector is copied at the time the connection object is created, and `close` destroys the copy.

An output raw connection is opened and creates an R raw vector internally. The raw vector can be retrieved *via* `rawConnectionValue`.

If a connection is open for both input and output the initial raw vector supplied is copied when the connections is open

Value

For `rawConnection`, a connection object of class `"rawConnection"` which inherits from class `"connection"`.

For `rawConnectionValue`, a raw vector.

Note

As output raw connections keep the internal raw vector up to date call-by-call, they are relatively expensive to use (although over-allocation is used), and it may be better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

See Also

[connections](#), [showConnections](#).

Examples

```
zz <- rawConnection(raw(0), "r+") # start with empty raw vector
writeBin(LETTERS, zz)
seek(zz, 0)
readLines(zz) # raw vector has embedded nuls
seek(zz, 0)
writeBin(letters[1:3], zz)
rawConnectionValue(zz)
close(zz)
```

rawConversion

Convert to or from (Bit/Packed) Raw Vectors

Description

Conversion to and from and manipulation of objects of type `"raw"`, both used as bits or “packed” 8 bits.

Usage

```
charToRaw(x)
rawToChar(x, multiple = FALSE)

rawShift(x, n)

rawToBits(x)
intToBits(x)
packBits(x, type = c("raw", "integer", "double"))

numToInts(x)
numToBits(x)
```

Arguments

<code>x</code>	object to be converted or shifted.
<code>multiple</code>	logical: should the conversion be to a single character string or multiple individual characters?
<code>n</code>	the number of bits to shift. Positive numbers shift right and negative numbers shift left: allowed values are $-8 \dots 8$.
<code>type</code>	the result type, partially matched.

Details

`packBits` accepts raw, integer or logical inputs, the last two without any NAs.

`numToBits(.)` and `packBits(., type="double")` are *inverse* functions of each other, see also the examples.

Note that ‘bytes’ are not necessarily the same as characters, e.g. in UTF-8 locales.

Value

`charToRaw` converts a length-one character string to raw bytes. It does so without taking into account any declared encoding (see [Encoding](#)).

`rawToChar` converts raw bytes either to a single character string or a character vector of single bytes (with `" "` for 0). (Note that a single character string could contain embedded NULs; only trailing nulls are allowed and will be removed.) In either case it is possible to create a result which is invalid in a multibyte locale, e.g. one using UTF-8. [Long vectors](#) are allowed if `multiple` is true.

`rawShift(x, n)` shift the bits in `x` by `n` positions to the right, see the argument `n`, above.

`rawToBits` returns a raw vector of 8 times the length of a raw vector with entries 0 or 1. `intToBits` returns a raw vector of 32 times the length of an integer vector with entries 0 or 1. (Non-integral numeric values are truncated to integers.) In both cases the unpacking is least-significant bit first.

`packBits` packs its input (using only the lowest bit for raw or integer vectors) least-significant bit first to a raw, integer or double (“numeric”) vector.

`numToInts()` and `numToBits()` split [double](#) precision numeric vectors either into two [integers](#) each or into 64 bits each, stored as raw. In both cases the unpacking is least-significant element first.

Examples

```
x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE

rawToChar(y)
rawToChar(y, multiple = TRUE)
(xx <- c(y, charToRaw("&"), charToRaw(" more")))
rawToChar(xx)

rawShift(y, 1)
rawShift(y, -2)

rawToBits(y)
```

```

showBits <- function(r) stats::symnum(as.logical(rawToBits(r)))

z <- as.raw(5)
z ; showBits(z)
showBits(rawShift(z, 1)) # shift to right
showBits(rawShift(z, 2))
showBits(z)
showBits(rawShift(z, -1)) # shift to left
showBits(rawShift(z, -2)) # ..
showBits(rawShift(z, -3)) # shifted off entirely

packBits(as.raw(0:31))
i <- -2:3
stopifnot(exprs = {
  identical(i, packBits(intToBits(i), "integer"))
  identical(packBits(      0:31) ,
            packBits(as.raw(0:31)))
})
str(pBi <- packBits(intToBits(i)))
data.frame(B = matrix(pBi, nrow=6, byrow=TRUE),
           hex = format(as.hexmode(i)), i)

## Look at internal bit representation of ...

## ... of integers :
bitI <- function(x) vapply(as.integer(x), function(x) {
  b <- substr(as.character(rev(intToBits(x))), 2L, 2L)
  paste0(c(b[1L], " ", b[2:32]), collapse = "")
}, "")

pbx <- apply(bx, 2, packBits, type="double")
stopifnot( identical(pbx, x))
```

RdUtils

*Utilities for Processing Rd Files***Description**

Utilities for converting files in R documentation (Rd) format to other formats or create indices from them, and for converting documentation in other formats to Rd format.

Usage

```
R CMD Rdconv [options] file
R CMD Rd2pdf [options] files
```

Arguments

file	the path to a file to be processed.
files	a list of file names specifying the R documentation sources to use, by either giving the paths to the files, or the path to a directory with the sources of a package.
options	further options to control the processing, or for obtaining information about usage and version of the utility.

Details

R CMD Rdconv converts Rd format to plain text, HTML or LaTeX formats: it can also extract the examples.

R CMD Rd2pdf is the user-level program for producing PDF output from Rd sources. It will make use of the environment variables R_PAPERSIZE (set by R CMD, with a default set when R was installed: values for R_PAPERSIZE are a4, letter, legal and executive) and R_PDFVIEWER (the PDF previewer). Also, RD2PDF_INPUTENC can be set to inputenx to make use of the LaTeX package of that name rather than inputenc: this might be needed for better support of the UTF-8 encoding.

R CMD Rd2pdf calls `tools::texi2pdf` to produce its PDF file: see its help for the possibilities for the `texi2dvi` command which that function uses (and which can be overridden by setting environment variable R_TEXI2DVICMD).

Use R CMD *foo* --help to obtain usage information on utility *foo*.

See Also

“[Processing documentation files](#)” in *Writing R Extensions*.

readBin

*Transfer Binary Data To and From Connections***Description**

Read binary data from or write binary data to a connection or raw vector.

Usage

```
readBin(con, what, n = 1L, size = NA_integer_, signed = TRUE,
        endian = .Platform$endian)

writeBin(object, con, size = NA_integer_,
        endian = .Platform$endian, useBytes = FALSE)
```

Arguments

con	A connection object or a character string naming a file or a raw vector.
what	Either an object whose mode will give the mode of the vector to be read, or a character vector of length one describing the mode: one of "numeric", "double", "integer", "int", "logical", "complex", "character", "raw".
n	numeric. The (maximal) number of records to be read. You can use an over-estimate here, but not too large as storage is reserved for n items.
size	integer. The number of bytes per element in the byte stream. The default, NA_integer_, uses the natural size. Size changing is not supported for raw and complex vectors.
signed	logical. Only used for integers of sizes 1 and 2, when it determines if the quantity on file should be regarded as a signed or unsigned integer.
endian	The endianness ("big" or "little") of the target system for the file. Using "swap" will force swapping endianness.
object	An R object to be written to the connection.
useBytes	See writeLines .

Details

These functions can only be used with binary-mode connections. If `con` is a character string, the functions call [file](#) to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If `readBin` is called with `con` a raw vector, the data in the vector is used as input. If `writeBin` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

If `size` is specified and not the natural size of the object, each element of the vector is coerced to an appropriate type before being written or as it is read. Possible sizes are 1, 2, 4 and possibly 8 for integer or logical vectors, and 4, 8 and possibly 12/16 for numeric vectors. (Note that coercion occurs as signed types except if `signed = FALSE` when reading integers of sizes 1 and 2.) Changing

sizes is unlikely to preserve NAs, and the extended precision sizes are unlikely to be portable across platforms.

`readBin` and `writeBin` read and write C-style zero-terminated character strings. Input strings are limited to 10000 characters. `readChar` and `writeChar` can be used to read and write fixed-length strings. No check is made that the string is valid in the current locale's encoding.

Handling R's missing and special (`Inf`, `-Inf` and `NaN`) values is discussed in “**Special values**” in *R Data Import/Export*.

Only $2^{31} - 1$ bytes can be written in a single call (and that is the maximum capacity of a raw vector on 32-bit platforms).

‘Endian-ness’ is relevant for `size > 1`, and should always be set for portable code (the default is only appropriate when writing and then reading files on the same platform).

Value

For `readBin`, a vector of appropriate mode and length the number of items read (which might be less than `n`).

For `writeBin`, a raw vector (if `con` is a raw vector) or invisibly `NULL`.

Note

Integer read/writes of size 8 will be available if either C type `long` is of size 8 bytes or C type `long long` exists and is of size 8 bytes.

Real read/writes of size `sizeof(long double)` (usually 12 or 16 bytes) will be available only if that type is available and different from `double`.

If `readBin(what = character())` is used incorrectly on a file which does not contain C-style character strings, warnings (usually many) are given. From a file or connection, the input will be broken into pieces of length 10000 with any final part being discarded.

See Also

“**Binary connections**” in *R Data Import/Export*.

`readChar` to read/write fixed-length strings.

`connections`, `readLines`, `writeLines`.

`.Machine` for the sizes of `long`, `long long` and `long double`.

Examples

```
zzfil <- tempfile("testbin")
zz <- file(zzfil, "wb")
writeBin(1:10, zz)
writeBin(pi, zz, endian = "swap")
writeBin(pi, zz, size = 4)
writeBin(pi^2, zz, size = 4, endian = "swap")
writeBin(pi+3i, zz)
writeBin("A test of a connection", zz)
z <- paste("A very long string", 1:100, collapse = " + ")
writeBin(z, zz)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  writeBin(as.integer(5^(1:10)), zz, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
  writeBin((pi/3)^(1:10), zz, size = s)
```

```

close(zz)

zz <- file(zzfil, "rb")
readBin(zz, integer(), 4)
readBin(zz, integer(), 6)
readBin(zz, numeric(), 1, endian = "swap")
readBin(zz, numeric(), size = 4)
readBin(zz, numeric(), size = 4, endian = "swap")
readBin(zz, complex(), 1)
readBin(zz, character(), 1)
z2 <- readBin(zz, character(), 1)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  readBin(zz, integer(), 10, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
  readBin(zz, numeric(), 10, size = s)
close(zz)
unlink(zzfil)
stopifnot(z2 == z)

## signed vs unsigned ints
zzfil <- tempfile("testbin")
zz <- file(zzfil, "wb")
x <- as.integer(seq(0, 255, 32))
writeBin(x, zz, size = 1)
writeBin(x, zz, size = 1)
x <- as.integer(seq(0, 60000, 10000))
writeBin(x, zz, size = 2)
writeBin(x, zz, size = 2)
close(zz)
zz <- file(zzfil, "rb")
readBin(zz, integer(), 8, size = 1)
readBin(zz, integer(), 8, size = 1, signed = FALSE)
readBin(zz, integer(), 7, size = 2)
readBin(zz, integer(), 7, size = 2, signed = FALSE)
close(zz)
unlink(zzfil)

## use of raw
z <- writeBin(pi^{1:5}, raw(), size = 4)
readBin(z, numeric(), 5, size = 4)
z <- writeBin(c("a", "test", "of", "character"), raw())
readBin(z, character(), 4)

```

readChar

Transfer Character Strings To and From Connections

Description

Transfer character strings to and from connections, without assuming they are null-terminated on the connection.

Usage

```
readChar(con, nchars, useBytes = FALSE)
```

```
writeChar(object, con, nchars = nchar(object, type = "chars"),
          eos = "", useBytes = FALSE)
```

Arguments

<code>con</code>	a connection object, or a character string naming a file, or a raw vector.
<code>nchars</code>	integer vector, giving the lengths in characters of (unterminated) character strings to be read or written. Elements must be ≥ 0 and not NA.
<code>useBytes</code>	logical: For <code>readChar</code> , should <code>nchars</code> be regarded as a number of bytes not characters in a multi-byte locale? For <code>writeChar</code> , see writeLines .
<code>object</code>	a character vector to be written to the connection, at least as long as <code>nchars</code> .
<code>eos</code>	‘end of string’: character string. The terminator to be written after each string, followed by an ASCII nul; use NULL for no terminator at all.

Details

These functions complement [readBin](#) and [writeBin](#) which read and write C-style zero-terminated character strings. They are for strings of known length, and can optionally write an end-of-string mark. They are intended only for character strings valid in the current locale.

These functions are intended to be used with binary-mode connections. If `con` is a character string, the functions call [file](#) to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If `readChar` is called with `con` a raw vector, the data in the vector is used as input. If `writeChar` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

Character strings containing ASCII nul(s) will be read correctly by `readChar` but truncated at the first nul with a warning.

If the character length requested for `readChar` is longer than the data available on the connection, what is available is returned. For `writeChar` if too many characters are requested the output is zero-padded, with a warning.

Missing strings are written as NA.

Value

For `readChar`, a character vector of length the number of items read (which might be less than `length(nchars)`).

For `writeChar`, a raw vector (if `con` is a raw vector) or invisibly NULL.

Note

Earlier versions of R allowed embedded NUL bytes within character strings, but not R $\geq 2.8.0$. `readChar` was commonly used to read fixed-size zero-padded byte fields for which `readBin` was unsuitable. `readChar` can still be used for such fields if there are no embedded NULs: otherwise `readBin(what = "raw")` provides an alternative.

`nchars` will be interpreted in bytes not characters in a non-UTF-8 multi-byte locale, with a warning.

There is little validity checking of UTF-8 reads.

Using these functions on a text-mode connection may work but should not be mixed with text-mode access to the connection, especially if the connection was opened with an `encoding` argument.

See Also

The manual *R Data Import/Export*.

[connections](#), [readLines](#), [writeLines](#), [readBin](#)

Examples

```
## test fixed-length strings
zzfil <- tempfile("testchar")
zz <- file(zzfil, "wb")
x <- c("a", "this will be truncated", "abc")
nc <- c(3, 10, 3)
writeChar(x, zz, nc, eos = NULL)
writeChar(x, zz, eos = "\r\n")
close(zz)

zz <- file(zzfil, "rb")
readChar(zz, nc)
readChar(zz, nchar(x)+3) # need to read the terminator explicitly
close(zz)
unlink(zzfil)
```

readline

Read a Line from the Terminal

Description

`readline` reads a line from the terminal (in interactive use).

Usage

```
readline(prompt = "")
```

Arguments

<code>prompt</code>	the string printed when prompting the user for input. Should usually end with a space " ".
---------------------	--

Details

The prompt string will be truncated to a maximum allowed length, normally 256 chars (but can be changed in the source code).

This can only be used in an [interactive](#) session.

Value

A character vector of length one. Both leading and trailing spaces and tabs are stripped from the result.

In non-[interactive](#) use the result is as if the response was RETURN and the value is "".

See Also

[readLines](#) for reading text lines from connections, including files.

Examples

```
fun <- function() {
  ANSWER <- readline("Are you a satisfied R user? ")
  ## a better version would check the answer less cursorily, and
  ## perhaps re-prompt
  if (substr(ANSWER, 1, 1) == "n")
    cat("This is impossible. YOU LIED!\n")
  else
    cat("I knew it.\n")
}
if(interactive()) fun()
```

readLines

Read Text Lines from a Connection

Description

Read some or all text lines from a connection.

Usage

```
readLines(con = stdin(), n = -1L, ok = TRUE, warn = TRUE,
          encoding = "unknown", skipNul = FALSE)
```

Arguments

con	a connection object or a character string.
n	integer. The (maximal) number of lines to read. Negative values indicate that one should read up to the end of input on the connection.
ok	logical. Is it OK to reach the end of the connection before <code>n > 0</code> lines are read? If not, an error will be generated.
warn	logical. Warn if a text file is missing a final EOL or if there are embedded NULs in the file.
encoding	encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1, UTF-8 or to be bytes: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection <code>con</code> or via options (<code>encoding=</code>): see the examples and ‘Details’.
skipNul	logical: should NULs be skipped?

Details

If the `con` is a character string, the function calls [file](#) to obtain a file connection which is opened for the duration of the function call. This can be a compressed file. ([tilde expansion](#) of the file path is done by `file`.)

If the connection is open it is read from its current position. If it is not open, it is opened in "rt" mode for the duration of the call and then closed (but not destroyed; one must call [close](#) to do that).

If the final line is incomplete (no final EOL marker) the behaviour depends on whether the connection is blocking or not. For a non-blocking text-mode connection the incomplete line is pushed back, silently. For all other connections the line will be accepted, with a warning.

Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line.

Embedded NULs in the input stream will terminate the line currently being read, with a warning (unless `skipNul = TRUE` or `warn = FALSE`).

If `con` is a not-already-open [connection](#) with a non-default `encoding` argument, the text is converted to UTF-8 and declared as such (and the `encoding` argument to `readLines` is ignored). See the examples.

Value

A character vector of length the number of lines read.

The elements of the result have a declared encoding if `encoding` is `"latin1"` or `"UTF-8"`,

Note

The default connection, `stdin`, may be different from `con = "stdin"`: see [file](#).

See Also

[connections](#), [writeLines](#), [readBin](#), [scan](#)

Examples

```
fil <- tempfile(fileext = ".data")
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = fil,
    sep = "\n")
readLines(fil, n = -1)
unlink(fil) # tidy up

## difference in blocking
fil <- tempfile("test")
cat("123\nabc", file = fil)
readLines(fil) # line with a warning

con <- file(fil, "r", blocking = FALSE)
readLines(con) # "123"
cat(" def\n", file = fil, append = TRUE)
readLines(con) # gets both
close(con)

unlink(fil) # tidy up

## Not run:
# read a 'Windows Unicode' file
A <- readLines(con <- file("Unicode.txt", encoding = "UCS-2LE"))
close(con)
unique(Encoding(A)) # will most likely be UTF-8

## End(Not run)
```

readRDS

*Serialization Interface for Single Objects***Description**

Functions to write a single R object to a file, and to restore it.

Usage

```
saveRDS(object, file = "", ascii = FALSE, version = NULL,
        compress = TRUE, refhook = NULL)

readRDS(file, refhook = NULL)
infoRDS(file)
```

Arguments

<code>object</code>	R object to serialize.
<code>file</code>	a connection or the path name of the file where the R object is saved to or read from.
<code>ascii</code>	a logical. If TRUE or NA, an ASCII representation is written; otherwise (default), a binary one is used. See the comments in the help for save .
<code>version</code>	the workspace format version to use. NULL specifies the current default version (3). The only other supported value is 2, the default from R 1.4.0 to R 3.5.0.
<code>compress</code>	a logical specifying whether saving to a named file is to use "gzip" compression, or one of "gzip", "bzip2", "xz" or "zstd" to indicate the type of compression to be used. Ignored if <code>file</code> is a connection.
<code>refhook</code>	a hook function for handling reference objects. See unserialize .

Details

`saveRDS` and `readRDS` provide the means to save a single R object to a connection (typically a file) and to restore the object, quite possibly under a different name. This differs from [save](#) and [load](#), which save and restore one or more named objects into an environment. They are widely used by R itself, for example to store metadata for a package and to store the [help.search](#) databases: the ".rds" file extension is most often used.

Functions [serialize](#) and [unserialize](#) provide a slightly lower-level interface to serialization: objects serialized to a connection by `serialize` can be read back by `readRDS` and conversely.

Function `infoRDS` retrieves meta-data about serialization produced by `saveRDS` or `serialize`. `infoRDS` cannot be used to detect whether a file is a serialization nor whether it is valid.

All of these interfaces use the same serialization format, but `save` writes a single line header (typically "RDXs\n") before the serialization of a single object (a pairlist of all the objects to be saved).

If `file` is a file name, it is opened by [gzfile](#) except for `save(compress = FALSE)` which uses [file](#). Only for the exception are marked encodings of `file` which cannot be translated to the native encoding handled on Windows.

Compression is handled by the connection opened when `file` is a file name, so is only possible when `file` is a connection if handled by the connection. So e.g. [url](#) connections will need to be wrapped in a call to [gzcon](#).

If a connection is supplied it will be opened (in binary mode) for the duration of the function if not already open: if it is already open it must be in binary mode for `saveRDS(ascii = FALSE)` or to read non-ASCII saves.

Value

For `readRDS`, an R object.

For `saveRDS`, NULL invisibly.

For `infoRDS`, an R list with elements `version` (version number, currently 2 or 3), `writer_version` (version of R that produced the serialization), `min_reader_version` (minimum version of R that can read the serialization), `format` (data representation) and `native_encoding` (native encoding of the session that produced the serialization, available since version 3). The data representation is given as `"xdr"` for big-endian binary representation, `"ascii"` for ASCII representation (produced via `ascii = TRUE` or `ascii = NA`) or `"binary"` (binary representation with native ‘endianness’ which can be produced by [serialize](#)).

Warning

Files produced by `saveRDS` (or `serialize` to a file connection) are not suitable as an interchange format between machines, for example to download from a website. The files produced by [save](#) have a header identifying the file type and so are better protected against erroneous use.

`compress = "zstd"` was first supported in R 4.5.0, and needs OS support so is even less suited as an interchange format.

See Also

[serialize](#), [save](#) and [load](#).

Section “[Serialization Formats](#)” in *R Internals* for details of the format used.

Examples

```
fil <- tempfile("women", fileext = ".rds")
## save a single object to file
saveRDS(women, fil)
## restore it under a different name
women2 <- readRDS(fil)
identical(women, women2)
## or examine the object via a connection, which will be opened as needed.
con <- gzfile(fil)
readRDS(con)
close(con)

## Less convenient ways to restore the object
## which demonstrate compatibility with unserialize()
con <- gzfile(fil, "rb")
identical(unserialize(con), women)
close(con)
con <- gzfile(fil, "rb")
wm <- readBin(con, "raw", n = 1e4) # size is a guess
close(con)
```

```
identical(unserialize(wm), women)

## Format compatibility with serialize():
fil2 <- tempfile("women")
con <- file(fil2, "w")
serialize(women, con) # ASCII, uncompressed
close(con)
identical(women, readRDS(fil2))
fil3 <- tempfile("women")
con <- bzfile(fil3, "w")
serialize(women, con) # binary, bzip2-compressed
close(con)
identical(women, readRDS(fil3))

unlink(c(fil, fil2, fil3))
```

readRenviron

Set Environment Variables from a File

Description

Read as file such as ‘.Renviron’ or ‘Renviron.site’ in the format described in the help for [Startup](#), and set environment variables as defined in the file.

Usage

```
readRenviron(path)
```

Arguments

path	A length-one character vector giving the path to the file. Tilde-expansion is performed where supported.
------	--

Value

Scalar logical indicating if the file was read successfully. Returned invisibly. If the file cannot be opened for reading, a warning is given.

See Also

[Startup](#) for the file format.

Examples

```
## Not run:
## re-read a startup file (or read it in a vanilla session)
readRenviron("~/Renviron")

## End(Not run)
```

`Recall`*Recursive Calling*

Description

`Recall` is used as a placeholder for the name of the function in which it is called. It allows the definition of recursive functions which still work after being renamed, see example below.

Usage

```
Recall(...)
```

Arguments

... all the arguments to be passed.

Note

`Recall` will not work correctly when passed as a function argument, e.g. to the `apply` family of functions.

See Also

`do.call` and `call`.

`local` for another way to write anonymous recursive functions.

Examples

```
## A trivial (but inefficient!) example:
fib <- function(n)
  if(n<=2) { if(n>=0) 1 else 0 } else Recall(n-1) + Recall(n-2)
fibonacci <- fib; rm(fib)
## renaming wouldn't work without Recall
fibonacci(10) # 55
```

`reg.finalizer`*Finalization of Objects*

Description

Registers an R function to be called upon garbage collection of object or (optionally) at the end of an R session.

Usage

```
reg.finalizer(e, f, onexit = FALSE)
```

Arguments

<code>e</code>	object to finalize. Must be an environment or an external pointer.
<code>f</code>	function to call on finalization. Must accept a single argument, which will be the object to finalize.
<code>onexit</code>	logical: should the finalizer be run if the object is still uncollected at the end of the R session?

Details

The main purpose of this function is to allow objects that refer to external items (a temporary file, say) to perform cleanup actions when they are no longer referenced from within R. This only makes sense for objects that are never copied on assignment, hence the restriction to environments and external pointers.

Inter alia, it provides a way to program code to be run at the end of an R session without manipulating `.Last`. For use in a package, it is often a good idea to set a finalizer on an object in the namespace: then it will be called at the end of the session, or soon after the namespace is unloaded if that is done during the session.

Value

NULL.

Note

R's interpreter is not re-entrant and the finalizer could be run in the middle of a computation. So there are many functions which it is potentially unsafe to call from `f`: one example which caused trouble is `options`. Finalizers are scheduled at garbage collection but only run at a relatively safe time thereafter.

See Also

`gc` and `Memory` for garbage collection and memory management.

Examples

```
f <- function(e) print("cleaning....")
g <- function(x){ e <- environment(); reg.finalizer(e, f) }
g()
invisible(gc()) # trigger cleanup
```

 regex

Regular Expressions as used in R

Description

This help page documents the regular expression patterns supported by `grep` and related functions `grepl`, `regexpr`, `gregexpr`, `sub` and `gsub`, as well as by `strsplit` and optionally by `agrep` and `agrep1`.

Details

A ‘regular expression’ is a pattern that describes a set of strings. Two types of regular expressions are used in R, *extended* regular expressions (the default) and *Perl-like* regular expressions used by `perl = TRUE`. There is also `fixed = TRUE` which can be considered to use a *literal* regular expression.

Other functions which use regular expressions (often via the use of `grep`) include `apropos`, `browseEnv`, `help.search`, `list.files` and `ls`. These will all use *extended* regular expressions.

Patterns are described here as they would be printed by `cat`: (*do remember that backslashes need to be doubled when entering R character strings*, e.g. from the keyboard).

Long regular expression patterns may or may not be accepted: the POSIX standard only requires up to 256 *bytes*.

Extended Regular Expressions

This section covers the regular expressions allowed in the default mode of `grep`, `grepl`, `regexpr`, `gregexpr`, `sub`, `gsub`, `regexec` and `strsplit`. They use an implementation of the POSIX 1003.2 standard: that allows some scope for interpretation and the interpretations here are those currently used by R. The implementation supports some extensions to the standard.

Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions. The whole expression matches zero or more characters (read ‘character’ as ‘byte’ if `useBytes = TRUE`).

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any metacharacter with special meaning may be quoted by preceding it with a backslash. The metacharacters in extended regular expressions are ‘. \ | () [{ ^ \$ * + ?’, but note that whether these have a special meaning depends on the context.

Escaping non-metacharacters with a backslash is implementation-dependent. The current implementation interprets ‘\a’ as ‘BEL’, ‘\e’ as ‘ESC’, ‘\f’ as ‘FF’, ‘\n’ as ‘LF’, ‘\r’ as ‘CR’ and ‘\t’ as ‘TAB’. (Note that these will be interpreted by R’s parser in literal character strings.)

A *character class* is a list of characters enclosed between ‘[’ and ‘]’ which matches any single character in that list; unless the first character of the list is the caret ‘^’, when it matches any character *not* in the list. For example, the regular expression ‘[0123456789]’ matches any single digit, and ‘[^abc]’ matches anything except the characters ‘a’, ‘b’ or ‘c’. A range of characters may be specified by giving the first and last characters, separated by a hyphen. (Because their interpretation is locale- and implementation-dependent, character ranges are best avoided. Some but not all implementations include both cases in ranges when doing caseless matching.) The only portable way to specify all ASCII letters is to list them all as the character class

‘[ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz]’.

(The current implementation uses numerical order of the encoding, normally a single-byte encoding or Unicode points.)

Certain named classes of characters are predefined. Their interpretation depends on the *locale* (see [locales](#)); the interpretation below is that of the POSIX locale.

‘[:alnum:]’ Alphanumeric characters: ‘[:alpha:]’ and ‘[:digit:]’.

‘[:alpha:]’ Alphabetic characters: ‘[:lower:]’ and ‘[:upper:]’.

‘[:blank:]’ Blank characters: space and tab, and possibly other locale-dependent characters, but on most platforms not including non-breaking space.

- `[:cntrl:]` Control characters. In ASCII, these characters have octal codes 000 through 037, and 177 (DEL). In another character set, these are the equivalent characters, if any.
- `[:digit:]` Digits: `'0 1 2 3 4 5 6 7 8 9'`.
- `[:graph:]` Graphical characters: `[:alnum:]` and `[:punct:]`.
- `[:lower:]` Lower-case letters in the current locale.
- `[:print:]` Printable characters: `[:alnum:]`, `[:punct:]` and space.
- `[:punct:]` Punctuation characters:
`'! " # $ % & ' ( ) * + , - . / : ; < = > ? @ [ \ ] ^ _ ` { | } ~'`.
- `[:space:]` Space characters: tab, newline, vertical tab, form feed, carriage return, space and possibly other locale-dependent characters – on most platforms this does not include non-breaking spaces.
- `[:upper:]` Upper-case letters in the current locale.
- `[:xdigit:]` Hexadecimal digits:
`'0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f'`.

For example, `[:alnum:]` means `[0-9A-Za-z]`, except the latter depends upon the locale and the character encoding, whereas the former is independent of locale and character set. (Note that the brackets in these class names are part of the symbolic names, and must be included in addition to the brackets delimiting the bracket list.) Most metacharacters lose their special meaning inside a character class. To include a literal `']`, place it first in the list. Similarly, to include a literal `^`, place it anywhere but first. Finally, to include a literal `-`, place it first or last (or, for `perl = TRUE` only, precede it by a backslash). (Only `^ - \ ]` are special inside character classes.)

The period `.` matches any single character. The symbol `\w` matches a ‘word’ character (a synonym for `[:alnum:]_`, an extension) and `\W` is its negation (`^[[:alnum:]_]`). Symbols `\d`, `\s`, `\D` and `\S` denote the digit and space classes and their negations (these are all extensions).

The caret `^` and the dollar sign `$` are metacharacters that respectively match the empty string at the beginning and end of a line. The symbols `\<` and `\>` match the empty string at the beginning and end of a word. The symbol `\b` matches the empty string at either edge of a word, and `\B` matches the empty string provided it is not at an edge of a word. (The interpretation of ‘word’ depends on the locale and implementation: these are all extensions.)

A regular expression may be followed by one of several repetition quantifiers:

- `?` The preceding item is optional and will be matched at most once.
- `*` The preceding item will be matched zero or more times.
- `+` The preceding item will be matched one or more times.
- `{n}` The preceding item is matched exactly `n` times.
- `{n, }` The preceding item is matched `n` or more times.
- `{n, m}` The preceding item is matched at least `n` times, but not more than `m` times.

By default repetition is greedy, so the maximal possible number of repeats is used. This can be changed to ‘minimal’ by appending `?` to the quantifier. (There are further quantifiers that allow approximate matching: see the TRE documentation.)

Regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating the substrings that match the concatenated subexpressions.

Two regular expressions may be joined by the infix operator `|`; the resulting regular expression matches any string matching either subexpression. For example, `abba|cde` matches either the

string `abba` or the string `cde`. Note that alternation does not work inside character classes, where `|` has its literal meaning.

Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole subexpression may be enclosed in parentheses to override these precedence rules.

The backreference `'\N'`, where `'N = 1 . . . 9'`, matches the substring previously matched by the Nth parenthesized subexpression of the regular expression. (This is an extension for extended regular expressions: POSIX defines them only for basic ones.)

Perl-like Regular Expressions

The `perl = TRUE` argument to `grep`, `regexpr`, `gregexpr`, `sub`, `gsub` and `strsplit` switches to the PCRE library that implements regular expression pattern matching using the same syntax and semantics as Perl 5.x, with just a few differences.

For complete details please consult the man pages for PCRE, especially `man pcrepattern` and `man pcreapi`, on your system or from the sources at <https://www.pcre.org>. (The version in use can be found by calling `extSoftVersion`. It need not be the version described in the system's man page. PCRE1 (reported as version < 10.00 by `extSoftVersion`) has been feature-frozen for some time (essentially 2012), the man pages at <https://www.pcre.org/original/doc/html/> should be a good match. PCRE2 (PCRE version >= 10.00) has man pages at <https://www.pcre.org/current/doc/html/>), but note that individual PCRE versions may still differ in behavior (e.g. PCRE 10.43 introduced quantifiers with an unspecified lower limit, but earlier versions documented that they were treated as literals).

Perl regular expressions can be computed byte-by-byte or (UTF-8) character-by-character: the latter is used in all multibyte locales and if any of the inputs are marked as UTF-8 (see [Encoding](#), or as Latin-1 except in a Latin-1 locale.

All the regular expressions described for extended regular expressions are accepted except `'\<'` and `'\>'`: in Perl all backslashed metacharacters are alphanumeric and backslashed symbols always are interpreted as a literal character. `'{'` is not special if it would be the start of an invalid interval specification. There can be more than 9 backreferences (but the replacement in `sub` can only refer to the first 9).

Character ranges are interpreted in the numerical order of the characters, either as bytes in a single-byte locale or as Unicode code points in UTF-8 mode. So in either case `'[A-Za-z]'` specifies the set of ASCII letters.

In UTF-8 mode the named character classes only match ASCII characters: see `'\p'` below for an alternative.

The construct `'(? . . .)'` is used for Perl extensions in a variety of ways depending on what immediately follows the `'?'`.

Perl-like matching can work in several modes, set by the options `'(?i)'` (caseless, equivalent to Perl's `'/i'`), `'(?m)'` (multiline, equivalent to Perl's `'/m'`), `'(?s)'` (single line, so a dot matches all characters, even new lines: equivalent to Perl's `'/s'`) and `'(?x)'` (extended, whitespace data characters are ignored unless escaped and comments are allowed: equivalent to Perl's `'/x'`). These can be concatenated, so for example, `'(?im)'` sets caseless multiline matching. It is also possible to unset these options by preceding the letter with a hyphen, and to combine setting and unsetting such as `'(?im-sx)'`. These settings can be applied within patterns, and then apply to the remainder of the pattern. Additional options not in Perl include `'(?U)'` to set 'ungreedy' mode (so matching is minimal unless `'?'` is used as part of the repetition quantifier, when it is greedy). Initially none of these options are set.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between `'\Q'` and `'\E'`. This is different from Perl in that `'$'` and `'@'` are handled as literals in `'\Q . . . \E'` sequences in PCRE, whereas in Perl, `'$'` and `'@'` cause variable interpolation.

The escape sequences `'\d'`, `'\s'` and `'\w'` represent any decimal digit, space character and ‘word’ character (letter, digit or underscore in the current locale: in UTF-8 mode only ASCII letters and digits are considered) respectively, and their upper-case versions represent their negation. Vertical tab was not regarded as a space character in a C locale before PCRE 8.34. Sequences `'\h'`, `'\v'`, `'\H'` and `'\V'` match horizontal and vertical space or the negation. (In UTF-8 mode, these do match non-ASCII Unicode code points.)

There are additional escape sequences: `'\cx'` is `'ctrl-x'` for any `'x'`, `'\ddd'` is the octal character (for up to three digits unless interpretable as a backreference, as `'\1'` to `'\7'` always are), and `'\xhh'` specifies a character by two hex digits. In a UTF-8 locale, `'\x{h...}'` specifies a Unicode code point by one or more hex digits. (Note that some of these will be interpreted by R’s parser in literal character strings.)

Outside a character class, `'\A'` matches at the start of a subject (even in multiline mode, unlike `'^'`), `'\Z'` matches at the end of a subject or before a newline at the end, `'\z'` matches only at end of a subject, and `'\G'` matches at first matching position in a subject (which is subtly different from Perl’s end of the previous match). `'\C'` matches a single byte, including a newline, but its use is warned against. In UTF-8 mode, `'\R'` matches any Unicode newline character (not just CR), and `'\X'` matches any number of Unicode characters that form an extended Unicode sequence. `'\X'`, `'\R'` and `'\B'` cannot be used inside a character class (with PCRE1, they are treated as characters `'X'`, `'R'` and `'B'`; with PCRE2 they cause an error).

A hyphen (minus) inside a character class is treated as a range, unless it is first or last character in the class definition. It can be quoted to represent the hyphen literal (`'\-'`). PCRE1 allows an unquoted hyphen at some other locations inside a character class where it cannot represent a valid range, but PCRE2 reports an error in such cases.

In UTF-8 mode, some Unicode properties may be supported via `'\p{xx}'` and `'\P{xx}'` which match characters with and without property `'xx'` respectively. For a list of supported properties see the PCRE documentation, but for example `'Lu'` is ‘upper case letter’ and `'Sc'` is ‘currency symbol’. Note that properties such as `'\w'`, `'\W'`, `'\d'`, `'\D'`, `'\s'`, `'\S'`, `'\b'` and `'\B'` by default do not refer to full Unicode, but one can override this by starting a pattern with `'(*UCP)'` (which comes with a performance penalty). (This support depends on the PCRE library being compiled with ‘Unicode property support’ which can be checked *via* [pcre_config](#). PCRE2 when compiled with Unicode support always supports also Unicode properties.)

The sequence `'(?#'` marks the start of a comment which continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part at all in the pattern matching.

If the extended option is set, an unescaped `'#'` character outside a character class introduces a comment that continues up to the next newline character in the pattern.

The pattern `'(?:...)'` groups characters just as parentheses do but does not make a backreference.

Patterns `'(?=...)'` and `'(?!...)'` are zero-width positive and negative lookahead *assertions*: they match if an attempt to match the ... forward from the current position would succeed (or not), but use up no characters in the string being processed. Patterns `'(?<=...)'` and `'(?<!...)'` are the lookbehind equivalents: they do not allow repetition quantifiers nor `'\C'` in ...

`regexr` and `gregexpr` support ‘named capture’. If groups are named, e.g., `"(?<first>[A-Z][a-z]+)"` then the positions of the matches are also returned by name. (Named backreferences are not supported by `sub`.)

Atomic grouping, possessive qualifiers and conditional and recursive patterns are not covered here.

regmatches

Extract or Replace Matched Substrings

Description

Extract or replace matched substrings from match data obtained by [regexpr](#), [gregexpr](#), [regexec](#) or [gregexec](#).

Usage

```
regmatches(x, m, invert = FALSE)
regmatches(x, m, invert = FALSE) <- value
```

Arguments

<code>x</code>	a character vector.
<code>m</code>	an object with match data.
<code>invert</code>	a logical: if TRUE, extract or replace the non-matched substrings.
<code>value</code>	an object with suitable replacement values for the matched or non-matched substrings (see Details).

Details

If `invert` is FALSE (default), `regmatches` extracts the matched substrings as specified by the match data. For vector match data (as obtained from [regexpr](#)), empty matches are dropped; for list match data, empty matches give empty components (zero-length character vectors).

If `invert` is TRUE, `regmatches` extracts the non-matched substrings, i.e., the strings are split according to the matches similar to [strsplit](#) (for vector match data, at most a single split is performed).

If `invert` is NA, `regmatches` extracts both non-matched and matched substrings, always starting and ending with a non-match (empty if the match occurred at the beginning or the end, respectively).

Note that the match data can be obtained from regular expression matching on a modified version of `x` with the same numbers of characters.

The replacement function can be used for replacing the matched or non-matched substrings. For vector match data, if `invert` is FALSE, `value` should be a character vector with length the number of matched elements in `m`. Otherwise, it should be a list of character vectors with the same length as `m`, each as long as the number of replacements needed. Replacement coerces values to character or list and generously recycles values as needed. Missing replacement values are not allowed.

Value

For `regmatches`, a character vector with the matched substrings if `m` is a vector and `invert` is `FALSE`. Otherwise, a list with the matched or/and non-matched substrings.

For `regmatches<-`, the updated character vector.

Examples

```
x <- c("A and B", "A, B and C", "A, B, C and D", "foobar")
pattern <- "[[:space:]]*(,|and)[[:space:]]"
## Match data from regexpr()
m <- regexpr(pattern, x)
regmatches(x, m)
regmatches(x, m, invert = TRUE)
## Match data from gregexpr()
m <- gregexpr(pattern, x)
regmatches(x, m)
regmatches(x, m, invert = TRUE)

## Consider
x <- "John (fishing, hunting), Paul (hiking, biking)"
## Suppose we want to split at the comma (plus spaces) between the
## persons, but not at the commas in the parenthesized hobby lists.
## One idea is to "blank out" the parenthesized parts to match the
## parts to be used for splitting, and extract the persons as the
## non-matched parts.
## First, match the parenthesized hobby lists.
m <- gregexpr("\\([^\)]*\)", x)
## Create blank strings with given numbers of characters.
blanks <- function(n) strrep(" ", n)
## Create a copy of x with the parenthesized parts blanked out.
s <- x
regmatches(s, m) <- Map(blanks, lapply(regmatches(s, m), nchar))
s
## Compute the positions of the split matches (note that we cannot call
## strsplit() on x with match data from s).
m <- gregexpr(" ", s)
## And finally extract the non-matched parts.
regmatches(x, m, invert = TRUE)

## regexec() and gregexec() return overlapping ranges because the
## first match is the full match. This conflicts with regmatches()<-
## and regmatches(..., invert=TRUE). We can work-around by dropping
## the first match.
drop_first <- function(x) {
  if(!anyNA(x) && all(x > 0)) {
    ml <- attr(x, 'match.length')
    if(is.matrix(x)) x <- x[-1,] else x <- x[-1]
    attr(x, 'match.length') <- if(is.matrix(ml)) ml[-1,] else ml[-1]
  }
  x
}
x <- gregexec("(\\w+) \\(((?:\\w+(?:, )?)+)\\)", x)
regmatches(x, m)
try(regmatches(x, m, invert=TRUE))
regmatches(x, lapply(m, drop_first))
## invert=TRUE loses matrix structure because we are retrieving what
```

```
## is in between every sub-match
regmatches(x, lapply(m, drop_first), invert=TRUE)
y <- z <- x
## Notice **list**(...) on the RHS
regmatches(y, lapply(m, drop_first)) <- list(c("<NAME>", "<HOBBY-LIST>"))
y
regmatches(z, lapply(m, drop_first), invert=TRUE) <-
  list(sprintf("<%d>", 1:5))
z

## With `perl = TRUE` and `invert = FALSE` capture group names
## are preserved. Collect functions and arguments in calls:
NEWS <- head(readLines(file.path(R.home("doc"), "NEWS.2")), 100)
m <- gregexec("(?<fun>\\w+)\\((?<args>[\\^]*?)\\)", NEWS, perl = TRUE)
y <- regmatches(NEWS, m)
y[[16]]
## Make tabular, adding original line numbers
mdat <- as.data.frame(t(do.call(cbind, y)))
mdat <- cbind(mdat, line=rep(seq_along(y), lengths(y) / ncol(mdat)))
head(mdat)
NEWS[head(mdat[['line']])]
```

remove

Remove Objects from a Specified Environment

Description

`remove` and `rm` are identical R functions that can be used to remove objects. These can be specified successively as character strings, or in the character vector `list`, or through a combination of both. All objects thus specified will be removed.

If `envir` is `NULL` then the currently active environment is searched first.

If `inherits` is `TRUE` then parents of the supplied directory are searched until a variable with the given name is encountered. A warning is printed for each variable that is not found.

Usage

```
remove(..., list = character(), pos = -1,
        envir = as.environment(pos), inherits = FALSE)

rm      (... , list = character(), pos = -1,
        envir = as.environment(pos), inherits = FALSE)
```

Arguments

<code>...</code>	the objects to be removed, as names (unquoted) or character strings (quoted).
<code>list</code>	a character vector (or <code>NULL</code>) naming objects to be removed.
<code>pos</code>	where to do the removal. By default, uses the current environment. See ‘details’ for other possibilities.
<code>envir</code>	the environment to use. See ‘details’.
<code>inherits</code>	should the enclosing frames of the environment be inspected?

Details

The `pos` argument can specify the environment from which to remove the objects in any of several ways: as an integer (the position in the `search` list); as the character string name of an element in the search list; or as an `environment` (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

It is not allowed to remove variables from the base environment and base namespace, nor from any environment which is locked (see `lockEnvironment`).

Earlier versions of R incorrectly claimed that supplying a character vector in `...` removed the objects named in the character vector, but it removed the character vector. Use the `list` argument to specify objects *via* a character vector.

`ls`, `objects`

Examples

```
tmp <- 1:4
## work with tmp and cleanup
rm(tmp)

## Not run:
## remove (almost) everything in the working environment.
## You will get no warning, so don't do this unless you are really sure.
rm(list = ls())

## End(Not run)
```

rep

Replicate Elements of Vectors and Vector-Like Objects

Description

`rep` replicates the values in `x`. It is a generic function, and the (internal) default method is described [here](#).

`rep.int` and `rep_len` are faster simplified versions for two common cases. Internally, they are generic, so methods can be defined for them (see [InternalMethods](#)). Except if `x` is a factor, when internal dispatch for `rep.int` and `rep_len` fails, there is an attempt to dispatch on the equivalent call to `rep`.

Usage

```
rep(x, ...)

rep.int(x, times)

rep_len(x, length.out)
```

Arguments

- `x` a vector (of any mode including a `list`) or a factor or (for `rep` only) a `POSIXct` or `POSIXlt` or `Date` object; or an S4 object containing such an object.
- `...` further arguments to be passed to or from other methods. For the internal default method these can include:
 - `times` an integer-valued vector giving the (non-negative) number of times to repeat each element if of length `length(x) * each`, or to repeat the whole vector if of length 1. Negative or NA values are an error. A double vector is accepted, other inputs being coerced to an integer or double vector.
 - `length.out` non-negative integer. The desired length of the output vector. Other inputs will be coerced to a double vector and the first element taken. Ignored if NA or invalid.
 - `each` non-negative integer. Each element of `x` is repeated `each` times. Other inputs will be coerced to an integer or double vector and the first element taken. Treated as 1 if NA or invalid.
- `times, length.out` see ... above.

Details

The default behaviour is as if the call was

```
rep(x, times = 1, length.out = NA, each = 1)
```

Normally just one of the additional arguments is specified, but if `each` is specified with either of the other two, its replication is performed first, and then that implied by `times` or `length.out`.

If `times` consists of a single integer, the result consists of the whole input repeated this many times. If `times` is a vector of the same length as `x` (after replication by `each`), the result consists of `x[1]` repeated `times[1]` times, `x[2]` repeated `times[2]` times and so on.

`length.out` may be given in place of `times`, in which case `x` is repeated as many times as is necessary to create a vector of this length. If both are given, `length.out` takes priority and `times` is ignored.

Non-integer values of `times` will be truncated towards zero. If `times` is a computed quantity it is prudent to add a small fuzz or use `round`. And analogously for `each`.

If `x` has length zero and `length.out` is supplied and is positive, the values are filled in using the extraction rules, that is by an NA of the appropriate class for an atomic vector (0 for raw vectors) and NULL for a list.

Value

An object of the same type as `x`.

`rep.int` and `rep.len` return no attributes (except the class and levels if returning a factor).

The default method of `rep` gives the result names (which will almost always contain duplicates) if `x` had names, but retains no other attributes.

Note

Function `rep.int` is a simple case which was provided as a separate function partly for S compatibility and partly for speed (especially when names can be dropped). The performance of `rep` has been improved since, but `rep.int` is still at least twice as fast when `x` has names.

The name `rep.int` long precedes making `rep` generic.

Function `rep` is a primitive, but (partial) matching of argument names is performed as for normal functions.

For historical reasons `rep` (only) works on `NULL`: the result is always `NULL` even when `length.out` is positive.

Although it has never been documented, these functions have always worked on [expression](#) vectors.

[seq](#), [sequence](#), [replicate](#).

Examples

```
rep(1:4, 2)
rep(1:4, each = 2)          # not the same.
rep(1:4, c(2,2,2,2))       # same as second.
rep(1:4, c(2,1,2,1))
rep(1:4, each = 2, length.out = 4)    # first 4 only.
rep(1:4, each = 2, length.out = 10)   # 8 integers plus two recycled 1's.
rep(1:4, each = 2, times = 3)        # length 24, 3 complete replications

rep(1, 40*(1-.8)) # length 7 on most platforms
rep(1, 40*(1-.8)+1e-7) # better

## replicate a list
fred <- list(happy = 1:10, name = "squash")
rep(fred, 5)

# date-time objects
x <- .leap.seconds[1:3]
rep(x, 2)
rep(as.POSIXlt(x), rep(2, 3))

## named factor
x <- factor(LETTERS[1:4]); names(x) <- letters[1:4]
x
rep(x, 2)
rep(x, each = 2)
rep.int(x, 2) # no names
rep_len(x, 10)
```

replace	<i>Replace Values in a Vector</i>
---------	-----------------------------------

Description

`replace` replaces the values in `x` with indices given in `list` by those given in `values`. If necessary, the values in `values` are recycled.

Usage

```
replace(x, list, values)
```

Arguments

<code>x</code>	a vector.
<code>list</code>	an index vector.
<code>values</code>	replacement values.

Value

A vector with the values replaced.

Note

`x` is unchanged: remember to assign the result.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Reserved	<i>Reserved Words in R</i>
----------	----------------------------

Description

The reserved words in R's parser are

```
if else repeat while function for in next break
```

```
TRUE FALSE NULL Inf NaN NA NA_integer_ NA_real_ NA_complex_
NA_character_
```

... and `..1`, `..2` etc, which are used to refer to arguments passed down from a calling function, see `...`.

Details

Reserved words outside [quotes](#) are always parsed to be references to the objects linked to in the 'Description', and hence they are not allowed as syntactic names (see [make.names](#)). They **are** allowed as non-syntactic names, e.g. inside [backtick](#) quotes.

rev

*Reverse Elements***Description**

`rev` provides a reversed version of its argument. It is generic function with a default method for vectors and one for [dendrograms](#).

To obtain a vector sorted in decreasing order efficiently, use `sort(x, decreasing = TRUE)`, not `rev(sort(x))`.

Usage

```
rev(x)
```

Arguments

`x` a vector or another object for which reversal is defined.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[seq](#), [sort](#).

Examples

```
x <- c(1:5, 5:3)
## sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1) #- don't need 'rev' here
```

Rhome

*Return the R Home Directory***Description**

Return the R home directory, or the full path to a component of the R installation.

Usage

```
R.home(component = "home")
```

Arguments

`component` "home" gives the R home directory, other known values are "bin", "doc", "etc", "include", "modules" and "share" giving the paths to the corresponding parts of an R installation.

Details

The R home directory is the top-level directory of the R installation being run.

The R home directory is often referred to as *R_HOME*, and is the value of an environment variable of that name in an R session. It can be found outside an R session by `R.RHOME`.

The paths to components often are subdirectories of *R_HOME* but need not be: "doc", "include" and "share" are not for some Linux binary installations of R.

Value

A character string giving the R home directory or path to a particular component. Normally the components are all subdirectories of the R home directory, but this need not be the case in a Unix-like installation.

The value for "modules" and on Windows "bin" is a sub-architecture-specific location. (This is not so for "etc", which may have sub-architecture-specific files as well as common ones.)

On a Unix-alike, the constructed paths are based on the current values of the environment variables *R_HOME* and where set *R_SHARE_DIR*, *R_DOC_DIR* and *R_INCLUDE_DIR* (these are set on startup and should not be altered).

On Windows the values of `R.home()` and *R_HOME* are switched to the 8.3 short form of path elements if required and if the Windows service to do that is enabled. The value of *R_HOME* is set to use forward slashes (since many package maintainers pass it unquoted to shells, for example in 'Makefile's).

See Also

`commandArgs()` [1] may provide related information.

Examples

```
## These result quite platform-dependently :
rbind(home = R.home(),
      bin  = R.home("bin")) # often the 'bin' sub directory of 'home'
                           # but not always ...
list.files(R.home("bin"))
```

rle

Run Length Encoding

Description

Compute the lengths and values of runs of equal values in a vector – or the reverse operation.

Usage

```
rle(x)
inverse.rle(x, ...)

## S3 method for class 'rle'
print(x, digits = getOption("digits"), prefix = "", ...)
```

Arguments

<code>x</code>	a vector (atomic, not a list) for <code>rle()</code> ; an object of class "rle" for <code>inverse.rle()</code> .
<code>...</code>	further arguments; ignored here.
<code>digits</code>	number of significant digits for printing, see <code>print.default</code> .
<code>prefix</code>	character string, prepended to each printed line.

Details

'vector' is used in the sense of `is.vector`.

Missing values are regarded as unequal to the previous value, even if that is also missing.

`inverse.rle()` is the inverse function of `rle()`, reconstructing `x` from the runs.

Value

`rle()` returns an object of class "rle" which is a list with components:

<code>lengths</code>	an integer vector containing the length of each run.
<code>values</code>	a vector of the same length as <code>lengths</code> with the corresponding values.

`inverse.rle()` returns an atomic vector.

Examples

```
x <- rev(rep(6:10, 1:5))
rle(x)
## lengths [1:5]  5 4 3 2 1
## values  [1:5] 10 9 8 7 6

z <- c(TRUE, TRUE, FALSE, FALSE, TRUE, FALSE, TRUE, TRUE, TRUE)
rle(z)
rle(as.character(z))
print(rle(z), prefix = "..| ")

N <- integer(0)
stopifnot(x == inverse.rle(rle(x)),
          identical(N, inverse.rle(rle(N))),
          z == inverse.rle(rle(z)))
```

Description

`ceiling` takes a single numeric argument `x` and returns a numeric vector containing the smallest integers not less than the corresponding elements of `x`.

`floor` takes a single numeric argument `x` and returns a numeric vector containing the largest integers not greater than the corresponding elements of `x`.

`trunc` takes a single numeric argument `x` and returns a numeric vector containing the integers formed by truncating the values in `x` toward 0.

`round` rounds the values in its first argument to the specified number of decimal places (default 0). See ‘Details’ about “round to even” when rounding off a 5.

`signif` rounds the values in its first argument to the specified number of *significant* digits. Hence, for numeric `x`, `signif(x, dig)` is the same as `round(x, dig - ceiling(log10(abs(x))))`.

Usage

```
ceiling(x)
floor(x)
trunc(x, ...)

round(x, digits = 0, ...)
signif(x, digits = 6)
```

Arguments

<code>x</code>	a numeric vector. Or, for <code>round</code> and <code>signif</code> , a complex vector.
<code>digits</code>	integer indicating the number of decimal places (<code>round</code>) or significant digits (<code>signif</code>) to be used. For <code>round</code> , negative values are allowed (see ‘Details’).
<code>...</code>	arguments to be passed to methods.

Details

These are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

Note that for rounding off a 5, the IEC 60559 standard (see also ‘IEEE 754’) is expected to be used, ‘*go to the even digit*’. Therefore `round(0.5)` is 0 and `round(-1.5)` is -2. However, this is dependent on OS services and on representation error (since e.g. 0.15 is not represented exactly, the rounding rule applies to the represented number and not to the printed number, and so `round(0.15, 1)` could be either 0.1 or 0.2).

Rounding to a negative number of digits means rounding to a power of ten, so for example `round(x, digits = -2)` rounds to the nearest hundred.

For `signif` the recognized values of `digits` are 1...22, and non-missing values are rounded to the nearest integer in that range. Each element of the vector is rounded individually, unlike printing.

These are all primitive functions.

S4 methods

These are all (internally) S4 generic.

`ceiling`, `floor` and `trunc` are members of the [Math](#) group generic. As an S4 generic, `trunc` has only one argument.

`round` and `signif` are members of the [Math2](#) group generic.

Warning

The realities of computer arithmetic can cause unexpected results, especially with `floor` and `ceiling`. For example, we ‘know’ that `floor(log(x, base = 8))` for `x = 8` is 1, but 0 has been seen on an R platform. It is normally necessary to use a tolerance.

Rounding to decimal digits in binary arithmetic is non-trivial (when `digits != 0`) and may be surprising. Be aware that most decimal fractions are *not* exactly representable in binary double precision. In R 4.0.0, the algorithm for `round(x, d)`, for $d > 0$, has been improved to *measure* and round “to nearest even”, contrary to earlier versions of R (or also to `sprintf()` or `format()` based rounding).

The ISO/IEC/IEEE 60559:2011 standard is available for money from <https://www.iso.org>.

The IEEE 754:2008 standard is more openly documented, e.g, at https://en.wikipedia.org/wiki/IEEE_754.

See Also

`as.integer`. Package **round**’s `roundX()` for several versions or implementations of rounding, including some previous and the current R version (as `version = "3d.C"`).

Examples

```
round(.5 + -2:4) # IEEE / IEC rounding: -2 0 0 2 2 4 4
## (this is *good* behaviour -- do *NOT* report it as bug !)
```

```
( x1 <- seq(-2, 4, by = .5) )
round(x1) #-- IEEE / IEC rounding !
x1[trunc(x1) != floor(x1)]
x1[round(x1) != floor(x1 + .5)]
(non.int <- ceiling(x1) != floor(x1))
```

```
x2 <- pi * 100^(-1:3)
round(x2, 3)
signif(x2, 3)
```

round.POSIXt

Round / Truncate Date-Time Objects

Description

Round or truncate date-time objects.

Usage

```
## S3 method for class 'POSIXt'
round(x,
      units = c("secs", "mins", "hours", "days", "months", "years"))
## S3 method for class 'POSIXt'
trunc(x,
      units = c("secs", "mins", "hours", "days", "months", "years"),
      ...)
```

```
## S3 method for class 'Date'
```

```
round(x, ...)
## S3 method for class 'Date'
trunc(x,
      units = c("secs", "mins", "hours", "days", "months", "years"),
      ...)
```

Arguments

x an object inheriting from "POSIXt" or "Date".

units one of the units listed, a string. Can be abbreviated.

... arguments to be passed to or from other methods, notably `digits` for `round`.

Details

The time is rounded or truncated to the second, minute, hour, day, month or year. Time zones are only relevant to days or more, when midnight in the current [time zone](#) is used.

For `units` arguments besides “months” and “years”, the methods for class "Date" are of little use except to remove fractional days.

Value

An object of class "POSIXlt" or "Date".

See Also

[round](#) for the generic function and default methods.

[DateTimeClasses](#), [Date](#)

Examples

```
round(.leap.seconds + 1000, "hour")

      trunc(Sys.time(), "day")
(timM <- trunc(Sys.time() -> St, "months")) # shows timezone
(datM <- trunc(Sys.Date() -> Sd, "months"))
(timY <- trunc(St, "years")) # + timezone
(datY <- trunc(Sd, "years"))

stopifnot(inherits(datM, "Date"), inherits(timM, "POSIXt"),
          substring(format(datM), 9,10) == "01", # first of month
          substring(format(datY), 6,10) == "01-01", # Jan 1
          identical(format(datM), format(timM)),
          identical(format(datY), format(timY)))
```

Description

Returns a matrix of integers indicating their row number in a matrix-like object, or a factor indicating the row labels.

Usage

```
row(x, as.factor = FALSE)
  .row(dim)
```

Arguments

<code>x</code>	a matrix-like object, that is one with a two-dimensional <code>dim</code> .
<code>dim</code>	a matrix dimension, i.e., an integer valued numeric vector of length two (with non-negative entries).
<code>as.factor</code>	a logical value indicating whether the value should be returned as a factor of row labels (created if necessary) rather than as numbers.

Value

An integer (or factor) matrix with the same dimensions as `x` and whose `i j`-th element is equal to `i` (or the `i`-th row label).

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`col` to get columns; `slice.index` for a general way to get slice indices in an array.

Examples

```
x <- matrix(1:12, 3, 4)
# extract the diagonal of a matrix - more slowly than diag(x)
dx <- x[row(x) == col(x)]
dx

# create an identity 5-by-5 matrix more slowly than diag(n = 5):
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
x

(i34 <- .row(3:4))
stopifnot(identical(i34, .row(c(3,4)))) # 'dim' maybe "double"
```

row+colnames

Row and Column Names

Description

Retrieve or set the row or column names of a matrix-like object.

Usage

```
rownames(x, do.NULL = TRUE, prefix = "row")
rownames(x) <- value

colnames(x, do.NULL = TRUE, prefix = "col")
colnames(x) <- value
```

Arguments

<code>x</code>	a matrix-like R object, with at least two dimensions for <code>colnames</code> .
<code>do.NULL</code>	logical. If FALSE and names are NULL, names are created.
<code>prefix</code>	for created names.
<code>value</code>	a valid value for that component of <code>dimnames(x)</code> . For a matrix or array this is either NULL or a character vector of non-zero length equal to the appropriate dimension.

Details

The extractor functions try to do something sensible for any matrix-like object `x`. If the object has `dimnames` the first component is used as the row names, and the second component (if any) is used for the column names. For a data frame, `rownames` and `colnames` eventually call `row.names` and `names` respectively, but the latter are preferred.

If `do.NULL` is FALSE, a character vector (of length `NROW(x)` or `NCOL(x)`) is returned in any case, prepending `prefix` to simple numbers, if there are no `dimnames` or the corresponding component of the `dimnames` is NULL.

The replacement methods for arrays/matrices coerce vector and factor values of `value` to character, but do not dispatch methods for `as.character`.

For a data frame, `value` for `rownames` should be a character vector of non-duplicated and non-missing names (this is enforced), and for `colnames` a character vector of (preferably) unique syntactically-valid names. In both cases, `value` will be coerced by `as.character`, and setting `colnames` will convert the row names to character.

Note

If the replacement versions are called on a matrix without any existing `dimnames`, they will add suitable `dimnames`. But constructions such as

```
rownames(x)[3] <- "c"
```

may not work unless `x` already has `dimnames`, since this will create a length-3 `value` from the NULL value of `rownames(x)`.

See Also

`dimnames`, `case.names`, `variable.names`.

Examples

```
m0 <- matrix(NA, 4, 0)
rownames(m0)

m2 <- cbind(1, 1:4)
colnames(m2, do.NULL = FALSE)
colnames(m2) <- c("x", "Y")
rownames(m2) <- rownames(m2, do.NULL = FALSE, prefix = "Obs.")
m2
```

row.names

Get and Set Row Names for Data Frames

Description

All data frames have row names, a character vector of length the number of rows with no duplicates nor missing values.

There are generic functions for getting and setting row names, with default methods for arrays. The description here is for the `data.frame` method.

``.rowNamesDF<-`` is a (non-generic replacement) function to set row names for data frames, with extra argument `make.names`. This function only exists as workaround as we cannot easily change the `row.names<-` generic without breaking legacy code in existing packages.

Usage

```
row.names(x)
row.names(x) <- value
.rowNamesDF(x, make.names=FALSE) <- value
```

Arguments

<code>x</code>	object of class <code>"data.frame"</code> , or any other class for which a method has been defined.
<code>make.names</code>	logical , i.e., one of <code>FALSE</code> , <code>NA</code> , <code>TRUE</code> , indicating what should happen if the specified row names, i.e., <code>value</code> , are invalid, e.g., duplicated or <code>NA</code> . The default (is back compatible), <code>FALSE</code> , will signal an error, where <code>NA</code> will “automatic” row names and <code>TRUE</code> will call make.names (<code>value</code> , <code>unique=TRUE</code>) for constructing valid names.
<code>value</code>	an object to be coerced to character unless an integer vector. It should have (after coercion) the same length as the number of rows of <code>x</code> with no duplicated nor missing values. <code>NULL</code> is also allowed: see ‘Details’.

Details

A data frame has (by definition) a vector of *row names* which has length the number of rows in the data frame, and contains neither missing nor duplicated values. Where a row names sequence has been added by the software to meet this requirement, they are regarded as ‘automatic’.

Row names are currently allowed to be integer or character, but for backwards compatibility (with `R <= 2.4.0`) `row.names` will always return a character vector. (Use `attr(x, "row.names")` if you need to retrieve an integer-valued set of row names.)

Using `NULL` for the value resets the row names to `seq_len(nrow(x))`, regarded as ‘automatic’.

Value

`row.names` returns a character vector.

`row.names<-` returns a data frame with the row names changed.

Note

`row.names` is similar to `rownames` for arrays, and it has a method that calls `rownames` for an array argument.

Row names of the form `1:n` for `n > 2` are stored internally in a compact form, which might be seen from C code or by deparsing but never via `row.names` or `attr(x, "row.names")`. Additionally, some names of this sort are marked as ‘automatic’ and handled differently by `as.matrix` and `data.matrix` (and potentially other functions). (All zero-row data frames are regarded as having automatic row names.)

See Also

`data.frame`, `rownames`, `names`.

`.row_names_info` for the internal representations.

Examples

```
## To illustrate the note:
df <- data.frame(x = c(TRUE, FALSE, NA, NA), y = c(12, 34, 56, 78))
row.names(df) <- 1 : 4
attr(df, "row.names") #> 1:4
deparse(df) # or dput(df)
##--> c(NA, 4L) : Compact storage, *not* regarded as automatic.

row.names(df) <- NULL
attr(df, "row.names") #> 1:4
deparse(df) # or dput(df) -- shows
##--> c(NA, -4L) : Compact storage, regarded as automatic.
```

rowsum

Give Column Sums of a Matrix or Data Frame, Based on a Grouping Variable

Description

Compute column sums across rows of a numeric matrix-like object for each level of a grouping variable. `rowsum` is generic, with a method for data frames and a default method for vectors and matrices.

Usage

```
rowsum(x, group, reorder = TRUE, ...)

## S3 method for class 'data.frame'
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)

## Default S3 method:
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)
```

Arguments

<code>x</code>	a matrix, data frame or vector of numeric data. Missing values are allowed. A numeric vector will be treated as a column vector.
<code>group</code>	a vector or factor giving the grouping, with one element per row of <code>x</code> . Missing values will be treated as another group and a warning will be given.
<code>reorder</code>	if <code>TRUE</code> , then the result will be in order of <code>sort(unique(group))</code> , if <code>FALSE</code> , it will be in the order that groups were encountered.
<code>na.rm</code>	logical (<code>TRUE</code> or <code>FALSE</code>). Should NA (including NaN) values be discarded?
<code>...</code>	other arguments to be passed to or from methods.

Details

The default is to reorder the rows to agree with `tapply` as in the example below. Reordering should not add noticeably to the time except when there are very many distinct values of `group` and `x` has few columns.

The original function was written by Terry Therneau, but this is a new implementation using hashing that is much faster for large matrices.

To sum over all the rows of a matrix (i.e., a single `group`) use `colSums`, which should be even faster.

For integer arguments, over/underflow in forming the sum results in NA.

Value

A matrix or data frame containing the sums. There will be one row per unique value of `group`.

See Also

[tapply](#), [aggregate](#), [rowSums](#)

Examples

```
require(stats)

x <- matrix(runif(100), ncol = 5)
group <- sample(1:8, 20, TRUE)
(xsum <- rowsum(x, group))
## Slower versions
tapply(x, list(group[row(x)], col(x)), sum)
t(sapply(split(as.data.frame(x), group), colSums))
aggregate(x, list(group), sum)[-1]
```

S3method

Register S3 Methods

Description

Register S3 methods in R scripts.

Usage

```
.S3method(generic, class, method)
```

Arguments

generic	a character string naming an S3 generic function.
class	a character string naming an S3 class.
method	a character string or function giving the S3 method to be registered. If not given, the function named <i>generic</i> . <i>class</i> is used.

Details

This function should only be used in R scripts: for package code, one should use the corresponding ‘S3method’ ‘NAMESPACE’ directive.

Examples

```
## Create a generic function and register a method for objects
## inheriting from class 'cls':
gen <- function(x) UseMethod("gen")
met <- function(x) writeLines("Hello world.")
.S3method("gen", "cls", met)
## Create an object inheriting from class 'cls', and call the
## generic on it:
x <- structure(123, class = "cls")
gen(x)
```

sample

Random Samples and Permutations

Description

sample takes a sample of the specified size from the elements of *x* using either with or without replacement.

Usage

```
sample(x, size, replace = FALSE, prob = NULL)

sample.int(n, size = n, replace = FALSE, prob = NULL,
           useHash = (n > 1e+07 && !replace && is.null(prob) && size <= n/2))
```

Arguments

<code>x</code>	either a vector of one or more elements from which to choose, or a positive integer. See ‘Details.’
<code>n</code>	a positive number, the number of items to choose from. See ‘Details.’
<code>size</code>	a non-negative integer giving the number of items to choose.
<code>replace</code>	should sampling be with replacement?
<code>prob</code>	a vector of probability weights for obtaining the elements of the vector being sampled.
<code>useHash</code>	<code>logical</code> indicating if the hash-version of the algorithm should be used. Can only be used for <code>replace = FALSE</code> , <code>prob = NULL</code> , and <code>size <= n/2</code> , and really should be used for large <code>n</code> , as <code>useHash=FALSE</code> will use memory proportional to <code>n</code> .

Details

If `x` has length 1, is numeric (in the sense of `is.numeric`) and `x >= 1`, sampling *via* `sample` takes place from `1:x`. *Note* that this convenience feature may lead to undesired behaviour when `x` is of varying length in calls such as `sample(x)`. See the examples.

Otherwise `x` can be any R object for which `length` and subsetting by integers make sense: S3 or S4 methods for these operations will be dispatched as appropriate.

For `sample` the default for `size` is the number of items inferred from the first argument, so that `sample(x)` generates a random permutation of the elements of `x` (or `1:x`).

It is allowed to ask for `size = 0` samples with `n = 0` or a length-zero `x`, but otherwise `n > 0` or positive `length(x)` is required.

Non-integer positive numerical values of `n` or `x` will be truncated to the next smallest integer, which has to be no larger than `.Machine$integer.max`.

The optional `prob` argument can be used to give a vector of weights for obtaining the elements of the vector being sampled. They need not sum to one, but they should be non-negative and not all zero. If `replace` is true, Walker’s alias method (Ripley 1987) is used when there are more than 200 reasonably probable values: this gives results incompatible with those from R < 2.2.0.

If `replace` is false, these probabilities are applied sequentially, that is the probability of choosing the next item is proportional to the weights amongst the remaining items. The number of nonzero weights must be at least `size` in this case.

`sample.int` is a bare interface in which both `n` and `size` must be supplied as integers.

Argument `n` can be larger than the largest integer of type `integer`, up to the largest representable integer in type `double`. Only uniform sampling is supported. Two random numbers are used to ensure uniform sampling of large integers.

Value

For `sample` a vector of length `size` with elements drawn from either `x` or from the integers `1:x`.

For `sample.int`, an integer vector of length `size` with elements from `1:n`, or a double vector if $n \geq 2^{31}$.

See Also

`RNGkind(sample.kind=..)` about random number generation, notably the change of `sample()` results with R version 3.6.0.

CRAN package **sampling** for other methods of weighted sampling without replacement.

Examples

```
x <- 1:12
# a random permutation
sample(x)
# bootstrap resampling -- only if length(x) > 1 !
sample(x, replace = TRUE)

# 100 Bernoulli trials
sample(c(0,1), 100, replace = TRUE)

## More careful bootstrapping -- Consider this when using sample()
## programmatically (i.e., in your function or simulation)!

# sample()'s surprise -- example
x <- 1:10
  sample(x[x > 8]) # length 2
  sample(x[x > 9]) # oops -- length 10!
  sample(x[x > 10]) # length 0

## safer version:
resample <- function(x, ...) x[sample.int(length(x), ...)]
resample(x[x > 8]) # length 2
resample(x[x > 9]) # length 1
resample(x[x > 10]) # length 0

## R 3.0.0 and later
sample.int(1e10, 12, replace = TRUE)
sample.int(1e10, 12) # not that there is much chance of duplicates
```

save

Save R Objects

Description

`save` writes an external representation of R objects to the specified file. The objects can be read back from the file at a later date by using the function `load` or `attach` (or `data` in some cases).

`save.image()` is just a short-cut for ‘save my current workspace’, i.e., `save(list = ls(all.names = TRUE), file = ".RData", envir = .GlobalEnv)`. It is also what happens with `q("yes")`.

Usage

```
save(..., list = character(),
      file = stop("'file' must be specified"),
      ascii = FALSE, version = NULL, envir = parent.frame(),
      compress = isTRUE(!ascii), compression_level,
```

```
eval.promises = TRUE, precheck = TRUE)

save.image(file = ".RData", version = NULL, ascii = FALSE,
           compress = !ascii, safe = TRUE)
```

Arguments

<code>...</code>	the names of the objects to be saved (as symbols or character strings).
<code>list</code>	a character vector (or <code>NULL</code>) containing the names of objects to be saved.
<code>file</code>	a (writable binary-mode) connection or the name of the file where the data will be saved (when tilde expansion is done). Must be a file name for <code>save.image</code> or <code>version = 1</code> .
<code>ascii</code>	if <code>TRUE</code> , an ASCII representation of the data is written. The default value of <code>ascii</code> is <code>FALSE</code> which leads to a binary file being written. If <code>NA</code> and <code>version >= 2</code> , a different ASCII representation is used which writes double/complex numbers as binary fractions.
<code>version</code>	the workspace format version to use. <code>NULL</code> specifies the current default format (3). Version 1 was the default from R 0.99.0 to R 1.3.1 and version 2 from R 1.4.0 to 3.5.0. Version 3 is supported from R 3.5.0.
<code>envir</code>	environment to search for objects to be saved.
<code>compress</code>	logical or character string specifying whether saving to a named file is to use compression. <code>TRUE</code> corresponds to <code>gzip</code> compression, and character strings <code>"gzip"</code> , <code>"bzip2"</code> , <code>"xz"</code> or <code>"zstd"</code> specify the type of compression. Ignored when <code>file</code> is a connection and for workspace format version 1.
<code>compression_level</code>	integer: the level of compression to be used. Defaults to 6 for <code>gzip</code> compression and to 9 for <code>bzip2</code> or <code>xz</code> compression. See the help for file for possible values and their merits.
<code>eval.promises</code>	logical: should objects which are promises be forced before saving?
<code>precheck</code>	logical: should the existence of the objects be checked before starting to save (and in particular before opening the file/connection)? Does not apply to version 1 saves.
<code>safe</code>	logical. If <code>TRUE</code> , a temporary file is used for creating the saved workspace. The temporary file is renamed to <code>file</code> if the save succeeds. This preserves an existing workspace <code>file</code> if the save fails, but at the cost of using extra disk space during the save.

Details

The names of the objects specified either as symbols (or character strings) in `...` or as a character vector in `list` are used to look up the objects from environment `envir`. By default [promises](#) are evaluated, but if `eval.promises = FALSE` promises are saved (together with their evaluation environments). (Promises embedded in objects are always saved unevaluated.)

All R platforms use the XDR (big-endian) representation of C ints and doubles in binary save-d files, and these are portable across all R platforms.

ASCII saves used to be useful for moving data between platforms but are now mainly of historical interest. They can be more compact than binary saves where compression is not used, but are almost always slower to both read and write: binary saves compress much better than ASCII ones. Further,

decimal ASCII saves may not restore double/complex values exactly, and what value is restored may depend on the R platform.

Default values for the `ascii`, `compress`, `safe` and `version` arguments can be modified with the `"save.defaults"` option (used both by `save` and `save.image`), see also the ‘Examples’ section. If a `"save.image.defaults"` option is set it is used in preference to `"save.defaults"` for function `save.image` (which allows this to have different defaults). In addition, `compression_level` can be part of the `"save.defaults"` option.

A connection that is not already open will be opened in mode `"wb"`. Supplying a connection which is open and not in binary mode gives an error.

Compression

Large files can be reduced considerably in size by compression. A particular 46MB R object was saved as 35MB without compression in 2 seconds, 22MB with `gzip` compression in 8 secs, 19MB with `bzip2` compression in 13 secs and 9.4MB with `xz` compression in 40 secs. The load times were 1.3, 2.8, 5.5 and 5.7 seconds respectively. These results are indicative, but the relative performances do depend on the actual file: `xz` compressed unusually well here.

It is possible to compress later (with `gzip`, `bzip2` or `xz`) a file saved with `compress = FALSE`: the effect is the same as saving with compression. Also, a saved file can be uncompressed and re-compressed under a different compression scheme (and see [resaveRdaFiles](#) for a way to do so from within R).

Parallel compression

That `file` can be a connection can be exploited to make use of an external parallel compression utility such as `pigz` (<https://zlib.net/pigz/>) or `pbzip2` (<https://launchpad.net/pbzip2>) via a `pipe` connection. For example, using 8 threads,

```
con <- pipe("pigz -p8 > fname.gz", "wb")
save(myObj, file = con); close(con)

con <- pipe("pbzip2 -p8 -9 > fname.bz2", "wb")
save(myObj, file = con); close(con)

con <- pipe("xz -T8 -6 -e > fname.xz", "wb")
save(myObj, file = con); close(con)
```

where the last requires `xz` 5.1.1 or later built with support for multiple threads (and parallel compression is only effective for large objects: at level 6 it will compress in serialized chunks of 12MB).

Warnings

The `...` arguments only give the *names* of the objects to be saved: they are searched for in the environment given by the `envir` argument, and the actual objects given as arguments need not be those found.

Saved R objects are binary files, even those saved with `ascii = TRUE`, so ensure that they are transferred without conversion of end-of-line markers and of 8-bit characters. The lines are delimited by LF on all platforms.

Although the default version was not changed between R 1.4.0 and R 3.4.4 nor since R 3.5.0, this does not mean that saved files are necessarily backwards compatible. You will be able to load a saved image into an earlier version of R which supports its version unless use is made of later additions (for example for version 2, raw vectors, external pointers and some S4 objects).

One such ‘later addition’ was [long vectors](#), introduced in R 3.0.0 and loadable only on 64-bit platforms (32-bit platforms are deprecated but still supported).

Loading files saved with `ASCII = NA` requires a C99-compliant C function `sscanf`: this was a problem on Windows, first worked around in R 3.1.2: version-2 files in that format should be readable in earlier versions of R on all other platforms.

`compress = "zstd"` was first supported in R 4.5.0 and needs (optional) OS support so is not recommended as an interchange format.

Note

For saving single R objects, [saveRDS\(\)](#) is mostly preferable to `save()`, notably because of the *functional* nature of [readRDS\(\)](#), as opposed to [load\(\)](#).

The most common reason for failure is lack of write permission in the current directory. For `save.image` and for saving at the end of a session this will shown by messages like

```
Error in gzfile(file, "wb") : unable to open connection
In addition: Warning message:
In gzfile(file, "wb") :
  cannot open compressed file '.RDataTmp',
  probable reason 'Permission denied'
```

See Also

[dput](#), [dump](#), [load](#), [data](#).

For other interfaces to the underlying serialization format, see [serialize](#) and [saveRDS](#).

Examples

```
x <- stats::runif(20)
y <- list(a = 1, b = TRUE, c = "oops")
save(x, y, file = "xy.RData")
save.image() # creating ".RData" in current working directory
unlink("xy.RData")

# set save defaults using option:
options(save.defaults = list(ascii = TRUE, safe = FALSE))
save.image() # creating ".RData"
if(interactive()) withAutoprint({
  file.info(".RData")
  readLines(".RData", n = 7) # first 7 lines; first starts w/ "RDA"..
})
unlink(".RData")
```

Description

`scale` is generic function whose default method centers and/or scales the columns of a numeric matrix.

Usage

```
scale(x, center = TRUE, scale = TRUE)
```

Arguments

<code>x</code>	a numeric matrix(like object).
<code>center</code>	either a logical value or numeric-alike vector of length equal to the number of columns of <code>x</code> , where ‘numeric-alike’ means that <code>as.numeric(.)</code> will be applied successfully if <code>is.numeric(.)</code> is not true.
<code>scale</code>	either a logical value or a numeric-alike vector of length equal to the number of columns of <code>x</code> .

Details

The value of `center` determines how column centering is performed. If `center` is a numeric-alike vector with length equal to the number of columns of `x`, then each column of `x` has the corresponding value from `center` subtracted from it. If `center` is `TRUE` then centering is done by subtracting the column means (omitting NAs) of `x` from their corresponding columns, and if `center` is `FALSE`, no centering is done.

The value of `scale` determines how column scaling is performed (after centering). If `scale` is a numeric-alike vector with length equal to the number of columns of `x`, then each column of `x` is divided by the corresponding value from `scale`. If `scale` is `TRUE` then scaling is done by dividing the (centered) columns of `x` by their standard deviations if `center` is `TRUE`, and the root mean square otherwise. If `scale` is `FALSE`, no scaling is done.

The root-mean-square for a (possibly centered) column is defined as $\sqrt{\sum(x^2)/(n-1)}$, where x is a vector of the non-missing values and n is the number of non-missing values. In the case `center = TRUE`, this is the same as the standard deviation, but in general it is not. (To scale by the standard deviations without centering, use `scale(x, center = FALSE, scale = apply(x, 2, sd, na.rm = TRUE))`.)

Value

For `scale.default`, the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes `"scaled:center"` and `"scaled:scale"`

See Also

[sweep](#) which allows centering (and scaling) with arbitrary statistics.

For working with the scale of a plot, see [par](#).

Examples

```
require(stats)
x <- matrix(1:10, ncol = 2)
(centered.x <- scale(x, scale = FALSE))
cov(centered.scaled.x <- scale(x)) # all 1
```

scan

*Read Data Values***Description**

Read data into a vector or list from the console or file.

Usage

```
scan(file = "", what = double(), nmax = -1, n = -1, sep = "",
      quote = if(identical(sep, "\n")) "" else "'\"", dec = ".",
      skip = 0, nlines = 0, na.strings = "NA",
      flush = FALSE, fill = FALSE, strip.white = FALSE,
      quiet = FALSE, blank.lines.skip = TRUE, multi.line = TRUE,
      comment.char = "", allowEscapes = FALSE,
      fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)
```

Arguments

- | | |
|------|--|
| file | <p>the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (or whatever <code>stdin()</code> reads if input is redirected or R is embedded). (In this case input can be terminated by a blank line or an EOF signal, 'Ctrl-D' on Unix and 'Ctrl-Z' on Windows.)</p> <p>Otherwise, the file name is interpreted <i>relative</i> to the current working directory (given by <code>getwd()</code>), unless it specifies an <i>absolute</i> path. Tilde-expansion is performed where supported. When running R from a script, <code>file = "stdin"</code> can be used to refer to the process's <code>stdin</code> file stream.</p> <p>This can be a compressed file (see file).</p> <p>Alternatively, <code>file</code> can be a connection, which will be opened if necessary, and if so closed at the end of the function call. Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line and so will match <code>sep = "\n"</code>.</p> <p><code>file</code> can also be a complete URL. (For the supported URL schemes, see the 'URLs' section of the help for url.)</p> <p>To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a file connection setting its <code>encoding</code> argument (or <code>scan</code>'s <code>fileEncoding</code> argument).</p> |
| what | <p>the type of what gives the type of data to be read. (Here 'type' is used in the sense of <code>typeof</code>.) The supported types are <code>logical</code>, <code>integer</code>, <code>numeric</code>, <code>complex</code>, <code>character</code>, <code>raw</code> and <code>list</code>. If <code>what</code> is a list, it is assumed that the lines of the data file are records each containing <code>length(what)</code> items ('fields') and the list components should have elements which are one of the first six (atomic) types listed or <code>NULL</code>, see section 'Details' below.</p> |
| nmax | <p>the maximum number of data values to be read, or if <code>what</code> is a list, the maximum number of records to be read. If omitted or not positive or an invalid value for an integer (and <code>nlines</code> is not set to a positive value), <code>scan</code> will read to the end of <code>file</code>.</p> |
| n | <p>integer: the maximum number of data values to be read, defaulting to no limit. Invalid values will be ignored.</p> |

sep	by default, scan expects to read ‘white-space’ delimited input fields. Alternatively, sep can be used to specify a character which delimits fields. A field is always delimited by an end-of-line marker unless it is quoted. If specified this should be the empty character string (the default) or NULL or a character string containing just one single-byte character.
quote	the set of quoting characters as a single character string or NULL. In a multibyte locale the quoting characters must be ASCII (single-byte).
dec	decimal point character. This should be a character string containing just one single-byte character. (NULL and a zero-length character vector are also accepted, and taken as the default.)
skip	the number of lines of the input file to skip before beginning to read data values.
nlines	if positive, the maximum number of lines of data to be read.
na.strings	character vector. Elements of this vector are to be interpreted as missing (NA) values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens <i>after</i> white space is stripped from the input (if enabled), so na.strings values may need their own white space stripped in advance.
flush	logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field, but precludes putting more than one record on a line.
fill	logical: if TRUE, scan will implicitly add empty fields to any lines with fewer fields than implied by what.
strip.white	vector of logical value(s) corresponding to items in the what argument. It is used only when sep has been specified, and allows the stripping of leading and trailing ‘white space’ from character fields (other fields are always stripped). Note: white space inside quoted strings is not stripped. If strip.white is of length 1, it applies to all fields; otherwise, if strip.white[i] is TRUE <i>and</i> the i-th field is of mode character (because what[i] is) then the leading and trailing unquoted white space from field i is stripped.
quiet	logical: if FALSE (default), print a line, saying how many items have been read.
blank.lines.skip	logical: if TRUE blank lines in the input are ignored, except when counting skip and nlines.
multi.line	logical. Only used if what is a list. If FALSE, all of a record must appear on one line (but more than one record can appear on a single line). Note that using fill = TRUE implies that a record will be terminated at the end of a line.
comment.char	character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether (the default).
allowEscapes	logical. Should C-style escapes such as ‘\n’ be processed (the default) or read verbatim? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). The escapes which are interpreted are the control characters ‘\a, \b, \f, \n, \r, \t, \v’ and octal and hexadecimal representations like ‘\040’ and ‘\0x2A’. Any other escaped character is treated as itself, including backslash. Note that Unicode escapes (starting ‘\u’ or ‘\U’: see Quotes) are never processed.

<code>fileEncoding</code>	character string: if non-empty declares the encoding used on a file (not a connection nor the keyboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <code>file</code> , and “ Variations on read.table ” in <i>R Data Import/Export</i> .
<code>encoding</code>	encoding to be assumed for input strings. If the value is <code>"latin1"</code> or <code>"UTF-8"</code> it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input (see <code>fileEncoding</code>). See also ‘Details’.
<code>text</code>	character string: if <code>file</code> is not supplied and this is, then data are read from the value of <code>text</code> via a text connection.
<code>skipNul</code>	logical: should NULs be skipped when reading character fields?

Details

The value of `what` can be a list of types, in which case `scan` returns a list of vectors with the types given by the types of the elements in `what`. This provides a way of reading columnar data. If any of the types is `NULL`, the corresponding field is skipped (but a `NULL` component appears in the result).

The type of `what` or its components can be one of the six atomic vector types or `NULL` (see [is.atomic](#)).

‘White space’ is defined for the purposes of this function as one or more contiguous characters from the set space, horizontal tab, carriage return and line feed (aka “newline”, `"\n"`). It does not include form feed nor vertical tab, but in Latin-1 and Windows 8-bit locales (but not UTF-8) ‘space’ includes the non-breaking space `"\xa0"`.

Empty numeric fields are always regarded as missing values. Empty character fields are scanned as empty character vectors, unless `na.strings` contains `" "` when they are regarded as missing values.

The allowed input for a numeric field is optional whitespace, followed by either `NA` or an optional sign followed by a decimal or hexadecimal constant (see [NumericConstants](#)), or `NaN`, `Inf` or `infinity` (ignoring case). Out-of-range values are recorded as `Inf`, `-Inf` or `0`.

For an integer field the allowed input is optional whitespace, followed by either `NA` or an optional sign and one or more digits (`'0-9'`): all out-of-range values are converted to `NA_integer_`.

If `sep` is the default (`" "`), the character `'\'` in a quoted string escapes the following character, so quotes may be included in the string by escaping them.

If `sep` is non-default, the fields may be quoted in the style of `' .csv'` files where separators inside quotes (`' '` or `" "`) are ignored and quotes may be put inside strings by doubling them. However, if `sep = "\n"` it is assumed by default that one wants to read entire lines verbatim.

Quoting is only interpreted in character fields and in `NULL` fields (which might be skipping character fields).

Note that since `sep` is a separator and not a terminator, reading a file by `scan("foo", sep = "\n", blank.lines.skip = FALSE)` will give an empty final line if the file ends in a line feed (`"\n"`) and not if it does not. This might not be what you expected; see also [readLines](#).

If `comment.char` occurs (except inside a quoted character field), it signals that the rest of the line should be regarded as a comment and be discarded. Lines beginning with a comment character (possibly after white space with the default separator) are treated as blank lines.

There is a line-length limit of 4095 bytes when reading from the console (which may impose a lower limit).

There is a check for a user interrupt every 1000 lines if `what` is a list, otherwise every 10000 items.

If `file` is a character string and `fileEncoding` is non-default, or if it is a not-already-open [connection](#) with a non-default encoding argument, the text is converted to UTF-8 and declared as such (and the encoding argument to `scan` is ignored). See the examples of [readLines](#).

Embedded NULs in the input stream will terminate the field currently being read, with a warning once per call to `scan`. Setting `skipNul = TRUE` causes them to be ignored.

Value

if `what` is a list, a list of the same length and same names (as any) as `what`.

Otherwise, a vector of the type of `what`.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".

Note

The default for `multi.line` differs from `S`. To read one record per line, use `flush = TRUE` and `multi.line = FALSE`. (Note that quoted character strings can still include embedded newlines.)

If number of items is not specified, the internal mechanism re-allocates memory in powers of two and so could use up to three times as much memory as needed. (It needs both old and new copies.) If you can, specify either `n` or `nmax` whenever inputting a large vector, and `nmax` or `nlines` when inputting a large list.

Using `scan` on an open connection to read partial lines can lose chars: use an explicit separator to avoid this.

Having nul bytes in fields (including ‘\0’ if `allowEscapes = TRUE`) may lead to interpretation of the field being terminated at the nul. They not normally present in text files – see [readBin](#).

See Also

[read.table](#) for more user-friendly reading of data matrices; [readLines](#) to read a file a line at a time. [write](#).

Quotes for the details of C-style escape sequences.

[readChar](#) and [readBin](#) to read fixed or variable length character strings or binary representations of numbers a few at a time from a connection.

Examples

```
cat("TITLE extra line", "2 3 5 7", "11 13 17", file = "ex.data", sep = "\n")
pp <- scan("ex.data", skip = 1, quiet = TRUE)
scan("ex.data", skip = 1)
scan("ex.data", skip = 1, nlines = 1) # only 1 line after the skipped one
scan("ex.data", what = list("", "", "")) # flush is F -> read "7"
scan("ex.data", what = list("", "", ""), flush = TRUE)
unlink("ex.data") # tidy up

## "inline" usage
scan(text = "1 2 3")
```

`search`*Give Search Path for R Objects*

Description

Gives a list of [attached packages](#) (see [library](#)), and R objects, usually `data.frames`.

Usage

```
search()  
searchpaths()
```

Value

A character vector, starting with `".GlobalEnv"`, and ending with `"package:base"` which is R's **base** package required always.

`searchpaths` gives a similar character vector, with the entries for packages being the path to the directory from which the namespace was loaded.

search()  
searchpaths()
```

`seek`*Functions to Reposition Connections*

Description

Functions to re-position connections.

Usage

```
seek(con, ...)
## S3 method for class 'connection'
seek(con, where = NA, origin = "start", rw = "", ...)

isSeekable(con)

truncate(con, ...)
```

Arguments

<code>con</code>	a connection .
<code>where</code>	numeric. A file position (relative to the origin specified by <code>origin</code>), or NA.
<code>rw</code>	character string. Empty or "read" or "write", partial matches allowed.
<code>origin</code>	character string. One of "start", "current", "end": see ‘Details’.
<code>...</code>	further arguments passed to or from other methods.

Details

`seek` with `where = NA` returns the current byte offset of a connection (from the beginning), and with a non-missing `where` argument the connection is re-positioned (if possible) to the specified position. `isSeekable` returns whether the connection in principle supports `seek`: currently only (possibly gz-compressed) file connections do.

`where` is stored as a real but should represent an integer: non-integer values are likely to be truncated. Note that the possible values can exceed the largest representable number in an R integer on 64-bit builds, and on some 32-bit builds.

File connections can be open for both writing/appending, in which case R keeps separate positions for reading and writing. Which `seek` refers to can be set by its `rw` argument: the default is the last mode (reading or writing) which was used. Most files are only opened for reading or writing and so default to that state. If a file is open for both reading and writing but has not been used, the default is to give the reading position (0).

The initial file position for reading is always at the beginning. The initial position for writing is at the beginning of the file for modes "r+" and "r+b", otherwise at the end of the file. Some platforms only allow writing at the end of the file in the append modes. (The reported write position for a file opened in an append mode will typically be unreliable until the file has been written to.)

gzfile connections support `seek` with a number of limitations, using the file position of the uncompressed file. They do not support `origin = "end"`. When writing, seeking is only possible forwards: when reading seeking backwards is supported by rewinding the file and re-reading from its start.

If `seek` is called with a non-NA value of `where`, any pushback on a text-mode connection is discarded.

`truncate` truncates a file opened for writing at its current position. It works only for file connections, and is not implemented on all platforms: on others (including Windows) it will not work for large (> 2Gb) files.

None of these should be expected to work on text-mode connections with re-encoding selected.

Value

`seek` returns the current position (before any move), as a (numeric) byte offset from the origin, if relevant, or 0 if not. Note that the position can exceed the largest representable number in an R integer on 64-bit builds, and on some 32-bit builds.

`truncate` returns `NULL`: it stops with an error if it fails (or is not implemented).

`isSeekable` returns a logical value, whether the connection supports `seek`.

Warning

Use of `seek` on Windows is discouraged. We have found so many errors in the Windows implementation of file positioning that users are advised to use it only at their own risk, and asked not to waste the R developers' time with bug reports on Windows' deficiencies.

[connections](#)

seq

Sequence Generation

Description

Generate regular sequences. `seq` is a standard generic with a default method. `seq.int` is a primitive which can be much faster but has a few restrictions. `seq_along` and `seq_len` are very fast primitives for two common cases.

Usage

```
seq(...)

## Default S3 method:
seq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
    length.out = NULL, along.with = NULL, ...)

seq.int(from, to, by, length.out, along.with, ...)

seq_along(along.with)
seq_len(length.out)
```

Arguments

<code>...</code>	arguments passed to or from methods.
<code>from,to</code>	the starting and (maximal) end values of the sequence. Of length 1 unless just <code>from</code> is supplied as an unnamed argument.
<code>by</code>	number: increment of the sequence.
<code>length.out</code>	desired length of the sequence. A non-negative number, which for <code>seq</code> and <code>seq.int</code> will be rounded up if fractional.
<code>along.with</code>	take the length from the length of this argument.

Details

Numerical inputs should all be [finite](#) (that is, not infinite, [NaN](#) or [NA](#)).

The interpretation of the unnamed arguments of `seq` and `seq.int` is *not* standard, and it is recommended always to name the arguments when programming.

`seq` is generic, and only the default method is described here. Note that it dispatches on the class of the **first** argument irrespective of argument names. This can have unintended consequences if it is called with just one argument intending this to be taken as `along.with`: it is much better to use `seq_along` in that case.

`seq.int` is an [internal generic](#) which dispatches on methods for "seq" based on the class of the first supplied argument (before argument matching).

Typical usages are

```
seq(from, to)
seq(from, to, by= )
seq(from, to, length.out= )
seq(along.with= )
seq(from)
seq(length.out= )
```

The first form generates the sequence `from, from+/-1, ..., to` (identical to `from:to`).

The second form generates `from, from+by, ..., up to the sequence value less than or equal to to`. Specifying `to - from` and `by` of opposite signs is an error. Note that the computed final value can go just beyond `to` to allow for rounding error, but is truncated to `to`. ('Just beyond' is by up to 10^{-10} times `abs(from - to)`.)

The third generates a sequence of `length.out` equally spaced values from `from` to `to`. (`length.out` is usually abbreviated to `length` or `len`, and `seq_len` is much faster.)

The fourth form generates the integer sequence `1, 2, ..., length(along.with)`. (`along.with` is usually abbreviated to `along`, and `seq_along` is much faster.)

The fifth form generates the sequence `1, 2, ..., length(from)` (as if argument `along.with` had been specified), *unless* the argument is numeric of length 1 when it is interpreted as `1:from` (even for `seq(0)` for compatibility with S). Using either `seq_along` or `seq_len` is much preferred (unless strict S compatibility is essential).

The final form generates the integer sequence `1, 2, ..., length.out` unless `length.out = 0`, when it generates `integer(0)`.

Very small sequences (with `from - to` of the order of 10^{-14} times the larger of the ends) will return `from`.

For `seq` (only), up to two of `from`, `to` and `by` can be supplied as complex values provided `length.out` or `along.with` is specified. More generally, the default method of `seq` will handle classed objects with methods for the `Math`, `Ops` and `Summary` group generics.

`seq.int`, `seq_along` and `seq_len` are [primitive](#).

Value

`seq.int` and the default method of `seq` for numeric arguments return a vector of type "integer" or "double": programmers should not rely on which.

`seq_along` and `seq_len` return an integer vector, unless it is a [long vector](#) when it will be double.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

The methods `seq.Date` and `seq.POSIXt`.
`., rep, sequence, row, col`.

Examples

```
seq(0, 1, length.out = 11)
seq(stats::rnorm(20)) # effectively 'along'
seq(1, 9, by = 2)      # matches 'end'
seq(1, 9, by = pi)     # stays below 'end'
seq(1, 6, by = 3)
seq(1.575, 5.125, by = 0.05)
seq(17) # same as 1:17, or even better seq_len(17)
```

seq.Date

Generate Regular Sequences of Dates

Description

The method for `seq` for objects of class `"Date"` representing calendar dates.

Usage

```
## S3 method for class 'Date'
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

<code>from</code>	starting date; optional.
<code>to</code>	end date; optional.
<code>by</code>	increment of the sequence; optional. See ‘Details’.
<code>length.out</code>	integer, optional. Desired length of the sequence.
<code>along.with</code>	optional; take the length from the length of this argument.
<code>...</code>	arguments passed to or from other methods.

Details

`by` can be specified in several ways.

- A number, taken to be in days.
- A object of class `difftime`
- A character string, containing one of `"day"`, `"week"`, `"month"`, `"quarter"` or `"year"`, or a `pmatch()` able abbreviation of these. This can optionally be preceded by a (positive or negative) integer and a space, or followed by `"s"`.
 See `seq.POSIXt` for the details of `"month"`.
 In the case `seq(from, to)`, the default for `by` is `"day"` (or `"1 day"`).

Value

A vector of class "Date". Type "integer" is often preserved on purpose, saving `object.size`.

See Also

[Date](#)

Examples

```
## first days of years
seq(as.Date("1910/1/1"), as.Date("1999/1/1"), "years")
## by month
seq(as.Date("2000/1/1"), by = "month", length.out = 12)
## quarters
seq(as.Date("2000/1/1"), as.Date("2003/1/1"), by = "quarter")

## 3-week period ending on a fixed date
seq(to = as.Date("2024-06-18"), by = "day", length.out = 21)

## find all 7th of the month _strictly_ inside two dates, the last being a 7th.
st <- as.Date("1998-12-17")
en <- as.Date("2000-1-7")
ll <- seq(en, st, by = "-1 month")
rev(ll[st < ll & ll < en])

## can abbreviate 'month' to 'm':
identical(seq(st, en, by = "m"),
          seq(st, en, by = "1 month"))
```

seq.POSIXt	<i>Generate Regular Sequences of Times</i>
------------	--

Description

The method for `seq` for date-time ("POSIXt") classes.

Usage

```
## S3 method for class 'POSIXt'
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

from	starting date; optional.
to	end date; optional.
by	increment of the sequence; optional. See ‘Details’.
length.out	integer, optional. Desired length of the sequence.
along.with	take the length from the length of this argument.
...	arguments passed to or from other methods.

Details

`by` can be specified in several ways.

- A number, taken to be in seconds.
- An object of class `difftime`
- A character string, containing one of "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year", or a `pmatch()` able abbreviation of these. This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".

The difference between "day" and "DSTday" is that the former ignores changes to/from daylight savings time and the latter takes the same clock time each day. "week" ignores DST (it is a period of 144 hours), but "7 DSTdays" can be used as an alternative. "month" and "year" allow for DST.

The `time zone` of the result is taken from `from` unless only `to` is provided: remember that GMT means UTC (and not the time zone of Greenwich, England) and so does not have daylight savings time.

Using "month" first advances the month without changing the day: if this results in an invalid day of the month, it is counted forward into the next month: see the examples.

Value

A vector of class "POSIXct", internally of type "double" or "integer".

See Also

[DateTimeClasses](#)

Examples

```
## first days of years
seq(ISOdate(1910,1,1), ISOdate(1999,1,1), "years")
## by month
seq(ISOdate(2000,1,1), by = "month", length.out = 12)
seq(ISOdate(2000,1,31), by = "month", length.out = 4)
## quarters
seq(ISOdate(1990,1,1), ISOdate(2000,1,1), by = "quarter") # or "3 months"
## days vs DSTdays: use c() to lose the time zone.
seq(c(ISOdate(2000,3,20)), by = "day", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "DSTday", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "7 DSTdays", length.out = 4)

## 24-hour period ending at a fixed time
seq(to = ISOdate(2024,1,2, 3,4,5), by = "hour", length.out = 24)
```

sequence

*Create A Vector of Sequences***Description**

The default method for `sequence` generates the sequence `seq(from[i], by = by[i], length.out = nvec[i])` for each element `i` in the parallel (and recycled) vectors `from`, `by` and `nvec`. Note that `nvec` is *not* recycled unless `recycle` is true, see ‘Details’. It then returns the result of concatenating those sequences.

Usage

```
sequence(nvec, ...)
## Default S3 method:
sequence(nvec, from = 1L, by = 1L,
         recycle = Sys.getenv("R_sequence_recycle", "false"), ...)
```

Arguments

<code>nvec</code>	coerced to a non-negative integer vector each element of which specifies the length of a sequence.
<code>from</code>	coerced to an integer vector each element of which specifies the first element of a sequence.
<code>by</code>	coerced to an integer vector each element of which specifies the step size between elements of a sequence.
<code>recycle</code>	<code>logical</code> or coercible to it, indicating if <code>nvec</code> is recycled, as it has always been documented to. We recommend to set this to <code>TRUE</code> explicitly, as that will become default, see ‘Details’.
<code>...</code>	additional arguments passed to methods.

Details

Negative values are supported for `from` and `by`. `sequence(nvec, from, by=0L)` is equivalent to `rep(from, each=nvec)`.

This function was originally implemented in R with fewer features, but it has since become more flexible, and the default method is implemented in C for speed.

Argument `recycle` is new since R 4.6.0; currently, the default is `FALSE` unless the environment variable `R_sequence_recycle` is set to a true value.

This provides back compatibility with R <= 4.5.z, where `from` and `by` are recycled or shortened to length `length(nvec)` in case that is shorter than the maximal length.

The plan is to replace the environment variable with an option (`getOption`) defaulting to `TRUE` and later to `TRUE` without a global option, to use R’s usual recycling semantic for all three arguments `nvec`, `from`, `by`.

Author(s)

Of the current version, Michael Lawrence based on code from the **S4Vectors** Bioconductor package

See Also

[gl](#), [seq](#), [rep](#).

Examples

```
sequence(c(3, 2)) # the concatenated sequences 1:3 and 1:2.
#> [1] 1 2 3 ' 1 2 (using ' to visualize the sub-sequences)
sequence(c(3, 2), from=2L) #> [1] 2 3 4 ' 2 3
sequence(c(3, 2), from=2L, by=2L) #> [1] 2 4 6 ' 2 4
sequence(c(3, 2), by=c(-1L, 1L)) #> [1] 1 0 -1 ' 1 2

## Cases where 'recycle' makes a difference:
sequence(3, 1:3) #> 1 2 3 (_currently_ -- will change in future!)
sequence(3, 1:3, recycle = FALSE) # back compatible: 1 2 3
sequence(3, 1:3, recycle = TRUE) # future default -- use in new code!
# --> 1 2 3 ' 2 3 4 ' 3 4 5
try(sequence(3, 1:3, 1[0], recycle = FALSE)) # an Error; default will be "empty":
sequence(3, 1:3, 1[0], recycle = TRUE) # |--> integer(0)
```

serialize

Simple Serialization Interface

Description

A simple low-level interface for serializing to connections.

Usage

```
serialize(object, connection, ascii, xdr = TRUE,
          version = NULL, refhook = NULL)

unserialize(connection, refhook = NULL)
```

Arguments

<code>object</code>	R object to serialize.
<code>connection</code>	an open connection or (for <code>serialize</code>) <code>NULL</code> or (for <code>unserialize</code>) a raw vector (see ‘Details’).
<code>ascii</code>	a logical. If <code>TRUE</code> or <code>NA</code> , an ASCII representation is written; otherwise (default) a binary one. See also the comments in the help for save .
<code>xdr</code>	a logical: if a binary representation is used, should a big-endian one (XDR) be used?
<code>version</code>	the workspace format version to use. <code>NULL</code> specifies the current default version (3). The only other supported value is 2, the default from R 1.4.0 to R 3.5.0.
<code>refhook</code>	a hook function for handling reference objects.

Details

The function `serialize` serializes `object` to the specified connection. If `connection` is `NULL` then `object` is serialized to a raw vector, which is returned as the result of `serialize`.

Sharing of reference objects is preserved within the object but not across separate calls to `serialize`.

`unserialize` reads an object (as written by `serialize`) from `connection` or a raw vector.

The `refhook` functions can be used to customize handling of non-system reference objects (all external pointers and weak references, and all environments other than namespace and package environments and `.GlobalEnv`). The hook function for `serialize` should return a character vector for references it wants to handle; otherwise it should return `NULL`. The hook for `unserialize` will be called with character vectors supplied to `serialize` and should return an appropriate object.

For a text-mode connection, the default value of `ascii` is set to `TRUE`: only ASCII representations can be written to text-mode connections and attempting to use `ascii = FALSE` will throw an error.

The format consists of a single line followed by the data: the first line contains a single character: `X` for binary serialization and `A` for ASCII serialization, followed by a new line. (The format used is identical to that used by `readRDS`.)

As almost all systems in current use are little-endian, `xdr = FALSE` can be used to avoid byte-shuffling at both ends when transferring data from one little-endian machine to another (or between processes on the same machine). Depending on the system, this can speed up serialization and unserialization by a factor of up to 3x.

Value

For `serialize`, `NULL` unless `connection = NULL`, when the result is returned in a raw vector.

For `unserialize` an R object.

Warning

These functions have provided a stable interface since R 2.4.0 (when the storage of serialized objects was changed from character to raw vectors). However, the serialization format may change in future versions of R, so this interface should not be used for long-term storage of R objects.

On 32-bit platforms a raw vector is limited to $2^{31} - 1$ bytes, but R objects can exceed this and their serializations will normally be larger than the objects.

See Also

`saveRDS` for a more convenient interface to serialize an object to a file or connection.

`save` and `load` to serialize and restore one or more named objects.

Section “**Serialization Formats**” in *R Internals* for details of the format used.

Examples

```
x <- serialize(list(1,2,3), NULL)
unserialize(x)

## see also the examples for saveRDS
```

sets

Set Operations

Description

Performs **set** union, intersection, (asymmetric!) difference, equality and membership on two vectors.

Usage

```
union(x, y)
intersect(x, y)
setdiff(x, y)
setequal(x, y)

is.element(el, set)
```

Arguments

`x, y, el, set` vectors (of the same mode) containing a sequence of items (conceptually) with no duplicated values.

Details

The set operations are intended for “same-kind” “vector-like” objects containing sequences of items. However, being “vector-like” cannot easily be ascertained (in particular as `is.vector()` enforces a very narrow concept of “vector”).

Thus, for `R < 4.5.0`, the set operands were always transformed via `as.vector()` (so that in particular, factors were coerced to character vectors). Starting with `R 4.5.0`, operands of the “same kind” (in the sense that `isa(x, class(y))` or `isa(y, class(x))` which appear to be “vector-like” (in the sense that `dim(x)` has length at most one, and subscripting `x` and/or `y` by `0L` leaves the class unchanged) are no longer transformed. In particular, union, intersection and set difference of two factors now give factors (see the examples).

`is.element(x, y)` is identical to `x %in% y` (after possibly transforming via `as.vector()`).

Value

For `union`, a vector of a common mode or class.

For `intersect`, a vector of a common mode or class, or `NULL` if `x` or `y` is `NULL`.

For `setdiff`, a vector of the same mode or class as `x`.

A logical scalar for `setequal` and a logical of the same length as `x` for `is.element`.

See Also

`%in%`

`'plotmath'` for the use of `union` and `intersect` in plot annotation.

Examples

```

(x <- c(sort(sample(1:20, 9)), NA))
(y <- c(sort(sample(3:23, 7)), NA))
union(x, y)
intersect(x, y)
setdiff(x, y)
setdiff(y, x)
setequal(x, y)

## True for all possible x & y :
setequal( union(x, y),
          c(setdiff(x, y), intersect(x, y), setdiff(y, x)))

is.element(x, y) # length 10
is.element(y, x) # length 8

## Factors:
x <- as.factor(c("A", "B", "A"))
y <- as.factor(c("B", "b"))
union(x, y)
intersect(x, y)
setdiff(x, y)
setdiff(y, x)
## (Note that union() and intersect() merge the levels.)

```

setTimeLimit

Set CPU and/or Elapsed Time Limits

Description

Functions to set CPU and/or elapsed time limits for top-level computations or the current session.

Usage

```

setTimeLimit(cpu = Inf, elapsed = Inf, transient = FALSE)

setSessionTimeLimit(cpu = Inf, elapsed = Inf)

```

Arguments

cpu, elapsed	double (of length one). Set a limit on the total or elapsed CPU time in seconds, respectively.
transient	logical. If TRUE, the limits apply only to the rest of the current computation.

Details

setTimeLimit sets limits which apply to each top-level computation, that is a command line (including any continuation lines) entered at the console or from a file. If it is called from within a computation the limits apply to the rest of the computation and (unless transient = TRUE) to subsequent top-level computations.

setSessionTimeLimit sets limits for the rest of the session. Once a session limit is reached it is reset to Inf.

Setting any limit has a small overhead – well under 1% on the systems measured.

Time limits are checked whenever a user interrupt could occur. This will happen frequently in R code and during `Sys.sleep`, but only at points in compiled C and Fortran code identified by the code author.

‘Total CPU time’ includes that used by child processes where the latter is reported.

showConnections	<i>Display Connections</i>
-----------------	----------------------------

Description

Display aspects of [connections](#).

Usage

```
showConnections(all = FALSE)
getConnection(what)
closeAllConnections()

stdin()
stdout()
stderr()
nullfile()

isatty(con)

getAllConnections()
```

Arguments

all	logical: if true all connections, including closed ones and the standard ones are displayed. If false only open user-created connections are included.
what	integer: a row number of the table given by <code>showConnections</code> .
con	a connection.

Details

`stdin()`, `stdout()` and `stderr()` are standard connections corresponding to input, output and error on the console respectively (and not necessarily to file streams). They are text-mode connections of class "terminal" which cannot be opened or closed, and are read-only, write-only and write-only respectively. The `stdout()` and `stderr()` connections can be re-directed by [sink](#) (and in some circumstances the output from `stdout()` can be split: see the help page).

The encoding for `stdin()` when redirected can be set by the command-line flag ‘--encoding’. `nullfile()` returns filename of the null device ("/dev/null" on Unix, "nul:" on Windows).

`showConnections` returns a matrix of information. If a connection object has been lost or forgotten, `getConnection` will take a row number from the table and return a connection object for that connection, which can be used to close the connection, for example. However, if there is

no R level object referring to the connection it will be closed automatically at the next garbage collection (except for `gzcon` connections).

`closeAllConnections` closes (and destroys) all user connections, restoring all `sink` diversions as it does so.

`isatty` returns true if the connection is one of the class "terminal" connections and it is apparently connected to a terminal, otherwise false. This may not be reliable in embedded applications, including GUI consoles.

`getAllConnections` returns a sequence of integer connection descriptors for use with `getConnection`, corresponding to the row names of the table returned by `showConnections(all = TRUE)`.

Value

`stdin()`, `stdout()` and `stderr()` return connection objects.

`showConnections` returns a character matrix of information with a row for each connection, by default only for open non-standard connections.

`getConnection` returns a connection object, or `NULL`.

Note

`stdin()` refers to the ‘console’ and not to the C-level ‘stdin’ of the process. The distinction matters in GUI consoles (which may not have an active ‘stdin’, and if they do it may not be connected to console input), and also in embedded applications. If you want access to the C-level file stream ‘stdin’, use `file("stdin")`.

When R is reading a script from a file, the *file* is the ‘console’: this is traditional usage to allow in-line data (see “**Scripting with R**” in *An Introduction to R* for an example).

Examples

```
showConnections(all = TRUE)
## Not run:
textConnection(letters)
# oops, I forgot to record that one
showConnections()
# class      description      mode text  isopen  can read can write
#3 "letters" "textConnection" "r"   "text" "opened" "yes"    "no"
mycon <- getConnection(3)

## End(Not run)

c(isatty(stdin()), isatty(stdout()), isatty(stderr()))
```

shQuote*Quote Strings for Use in OS Shells*

Description

Quote a string to be passed to an operating system shell.

Usage

```
shQuote(string, type = c("sh", "csh", "cmd", "cmd2"))
```

Arguments

string	a character vector, usually of length one.
type	character: the type of shell quoting. Partial matching is supported. "cmd" and "cmd2" refer to the Windows shell. "cmd" is the default under Windows.

Details

The default type of quoting supported under Unix-alikes is that for the Bourne shell `sh`. If the string does not contain single quotes, we can just surround it with single quotes. Otherwise, the string is surrounded in double quotes, which suppresses all special meanings of metacharacters except dollar, backquote and backslash, so these (and of course double quote) are preceded by backslash. This type of quoting is also appropriate for `bash`, `ksh` and `zsh`.

The other type of quoting is for the C-shell (`csh` and `tcsh`). Once again, if the string does not contain single quotes, we can just surround it with single quotes. If it does contain single quotes, we can use double quotes provided it does not contain dollar or backquote (and we need to escape backslash, exclamation mark and double quote). As a last resort, we need to split the string into pieces not containing single quotes (some may be empty) and surround each with single quotes, and the single quotes with double quotes.

In Windows, command line interpretation is done by the application as well as the shell. It may depend on the compiler used: Microsoft's rules for the C run-time are given at <https://learn.microsoft.com/en-us/cpp/c-language/parsing-c-command-line-arguments?view=msvc-160>. It may depend on the whim of the programmer of the application: check its documentation. The `type = "cmd"` prepares the string for parsing as an argument by the Microsoft's rules and makes `shQuote` safe for use with many applications when used with `system` or `system2`. It surrounds the string by double quotes and escapes internal double quotes by a backslash. Any trailing backslashes and backslashes that were originally before double quotes are doubled.

The Windows `cmd.exe` shell (used by default with `shell`) uses `type = "cmd2"` quoting: special characters are prefixed with `"^"`. In some cases, two types of quoting should be used: first for the application, and then `type = "cmd2"` for `cmd.exe`. See the examples below.

Value

A character vector of the same length as `string`.

See Also

[Quotes](#) for quoting R code.

[sQuote](#) for quoting English text.

Examples

```
test <- "abc$def`gh`i\\j"
cat(shQuote(test), "\n")
## Not run: system(paste("echo", shQuote(test)))
test <- "don't do it!"
cat(shQuote(test), "\n")

tryit <- paste("use the", sQuote("-c"), "switch\nlike this")
cat(shQuote(tryit), "\n")
## Not run: system(paste("echo", shQuote(tryit)))
cat(shQuote(tryit, type = "csh"), "\n")

## Windows-only example, assuming cmd.exe:
perlcmd <- 'print "Hello World\\n";'
## Not run:
shell(shQuote(paste("perl -e",
                    shQuote(perlcmd, type = "cmd")),
      type = "cmd2"))

## End(Not run)
```

sign

Sign Function

Description

`sign` returns a vector with the signs of the corresponding elements of `x` (the sign of a real number is 1, 0, or -1 if the number is positive, zero, or negative, respectively).

Note that `sign` does not operate on complex vectors.

Usage

```
sign(x)
```

Arguments

`x` a numeric vector

Details

This is an [internal generic primitive](#) function: methods can be defined for it directly or via the [Math](#) group generic.

See Also[abs](#)**Examples**

```
sign(pi)      # == 1
sign(-2:3)    # -1 -1 0 1 1 1
```

Signals*Interrupting Execution of R*

Description

On receiving `SIGUSR1` R will save the workspace and quit. `SIGUSR2` has the same result except that the `.Last` function and `on.exit` expressions will not be called.

Usage

```
kill -USR1 pid
kill -USR2 pid
```

Arguments

`pid` The process ID of the R process.

Details

The commands history will also be saved if would be at normal termination.

This is not available on Windows, and possibly on other OSes which do not support these signals.

Warning

It is possible that one or more R objects will be undergoing modification at the time the signal is sent. These objects could be saved in a corrupted form.

See Also

[Sys.getpid](#) to report the process ID for future use.

sink

*Send R Output to a File***Description**

`sink` diverts R output to a connection (and stops such diversions).

`sink.number()` reports how many diversions are in use.

`sink.number(type = "message")` reports the number of the connection currently being used for error messages.

Usage

```
sink(file = NULL, append = FALSE, type = c("output", "message"),
      split = FALSE)
```

```
sink.number(type = c("output", "message"))
```

Arguments

<code>file</code>	a writable connection or a character string naming the file to write to, or NULL to stop sink-ing.
<code>append</code>	logical. If TRUE, output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .
<code>type</code>	character string. Either the output stream or the messages stream. The name will be partially matched so can be abbreviated.
<code>split</code>	logical: if TRUE, output will be sent to the new sink and to the current output stream, like the Unix program <code>tee</code> .

Details

`sink` diverts R output to a connection (and must be used again to finish such a diversion, see below!). If `file` is a character string, a file connection with that name will be established for the duration of the diversion.

Normal R output (to connection `stdout`) is diverted by the default `type = "output"`. Only prompts and (most) messages continue to appear on the console. Messages sent to `stderr()` (including those from `message`, `warning` and `stop`) can be diverted by `sink(type = "message")` (see below).

`sink()` or `sink(file = NULL)` ends the last diversion (of the specified type). There is a stack of diversions for normal output, so output reverts to the previous diversion (if there was one). The stack is of up to 21 connections (20 diversions).

If `file` is a connection it will be opened if necessary (in "wt" mode) and closed once it is removed from the stack of diversions.

`split = TRUE` only splits R output (via `Rvprintf`) and the default output from `writeLines`: it does not split all output that might be sent to `stdout()`.

Sink-ing the messages stream should be done only with great care. For that stream `file` must be an already open connection, and there is no stack of connections.

If `file` is a character string, the file will be opened using the current encoding. If you want a different encoding (e.g., to represent strings which have been stored in UTF-8), use a [file](#)

connection — but some ways to produce R output will already have converted such strings to the current encoding.

Value

`sink` returns `NULL`.

For `sink.number()` the number (0, 1, 2, ...) of diversions of output in place.

For `sink.number("message")` the connection number used for messages, 2 if no diversion has been used.

Warning

Do not use a connection that is open for `sink` for any other purpose. The software will stop you closing one such inadvertently.

Do not sink the messages stream unless you understand the source code implementing it and hence the pitfalls.

[capture.output](#)

Examples

```
sink("sink-examp.txt")
i <- 1:10
outer(i, i)
sink()

## capture all the output to a file.
zz <- file("all.Rout", open = "wt")
sink(zz)
sink(zz, type = "message")
try(log("a"))
## revert output back to the console -- only then access the file!
sink(type = "message")
sink()
file.show("all.Rout", delete.file = TRUE)
```

 slice.index

Slice Indexes in an Array

Description

Returns a matrix of integers indicating the number of their slice in a given array.

Usage

```
slice.index(x, MARGIN)
```

Arguments

<code>x</code>	an array. If <code>x</code> has no dimension attribute, it is considered a one-dimensional array.
<code>MARGIN</code>	an integer vector giving the dimension numbers to slice by.

Details

If `MARGIN` gives a single dimension, then all elements of slice number `i` with respect to this have value `i`. In general, slice numbers are obtained by numbering all combinations of indices in the dimensions given by `MARGIN` in column-major order. I.e., with $m_1, \dots, m_k$ the dimension numbers (elements of `MARGIN`) sliced by and $d_{m_1}, \dots, d_{m_k}$ the corresponding extents, and $n_1 = 1, n_2 = d_{m_1}, \dots, n_k = d_{m_1} \cdots d_{m_{k-1}}$, the number of the slice where dimension m_1 has value $i_1, \dots$, dimension m_k has value i_k is $1 + n_1(i_1 - 1) + \cdots + n_k(i_k - 1)$.

Value

An integer array `y` with dimensions corresponding to those of `x`.

See Also

`row` and `col` for determining row and column indexes; in fact, these are special cases of `slice.index` corresponding to `MARGIN` equal to 1 and 2, respectively when `x` is a matrix.

Examples

```
x <- array(1 : 24, c(2, 3, 4))
slice.index(x, 2)
slice.index(x, c(1, 3))
## When slicing by dimensions 1 and 3, slice index 5 is obtained for
## dimension 1 has value 1 and dimension 3 has value 3 (see above):
which(slice.index(x, c(1, 3)) == 5, arr.ind = TRUE)
```

slotOp*Extract or Replace a Slot or Property*

Description

Extract or replace the contents of a slot or property of an object.

Usage

```
object@name  
object@name <- value
```

Arguments

<code>object</code>	An object from a formally defined (S4) class, or an object with a class for which '@' or '@<-' S3 methods are defined.
<code>name</code>	The name of the slot or property, supplied as a character string or unquoted symbol. If <code>object</code> has an S4 class, then <code>name</code> must be the name of a slot in the definition of the class of <code>object</code> .
<code>value</code>	A suitable replacement value for the slot or property. For an S4 object this must be from a class compatible with the class defined for this slot in the definition of the class of <code>object</code> .

Details

If `object` is not an S4 object, then a suitable S3 method for '@' or '@<-' is searched for. If no method is found, then an error is signaled.

if `object` is an S4 object, then these operators are for slot access, and are enabled only when package **methods** is loaded (as per default). The slot must be formally defined. (There is an exception for the name `.Data`, intended for internal use only.) The replacement operator checks that the slot already exists on the object (which it should if the object is really from the class it claims to be). See [slot](#) for further details, in particular for the differences between `slot()` and the @ operator.

These are internal generic operators: see [InternalMethods](#).

Value

The current contents of the slot.

[Extract](#), [slot](#)

socketSelect

Wait on Socket Connections

Description

Waits for the first of several socket connections and server sockets to become available.

Usage

```
socketSelect(socklist, write = FALSE, timeout = NULL)
```

Arguments

socklist	list of open socket connections and server sockets.
write	logical. If TRUE wait for corresponding socket to become available for writing; otherwise wait for it to become available for reading or for accepting an incoming connection (server sockets).
timeout	numeric or NULL. Time in seconds to wait for a socket to become available; NULL means wait indefinitely.

Details

The values in `write` are recycled if necessary to make up a logical vector the same length as `socklist`. Socket connections can appear more than once in `socklist`; this can be useful if you want to determine whether a socket is available for reading or writing.

Value

Logical the same length as `socklist` indicating whether the corresponding socket connection is available for output or input, depending on the corresponding value of `write`. Server sockets can only become available for input.

Examples

```
## Not run:
## test whether socket connection s is available for writing or reading
socketSelect(list(s, s), c(TRUE, FALSE), timeout = 0)

## End(Not run)
```

solve

Solve a System of Equations

Description

This generic function solves the equation $a \cdot x = b$ for x , where b can be either a vector or a matrix.

Usage

```
solve(a, b, ...)

## Default S3 method:
solve(a, b, tol, LINPACK = FALSE, ...)
```

Arguments

<code>a</code>	a square numeric or complex matrix containing the coefficients of the linear system. Logical matrices are coerced to numeric.
<code>b</code>	a numeric or complex vector or matrix giving the right-hand side(s) of the linear system. If missing, <code>b</code> is taken to be an identity matrix and <code>solve</code> will return the inverse of <code>a</code> .
<code>tol</code>	the tolerance for detecting linear dependencies in the columns of <code>a</code> . The default is <code>.Machine\$double.eps</code> .
<code>LINPACK</code>	logical. Defunct and an error.
<code>...</code>	further arguments passed to or from other methods.

Details

`a` or `b` can be complex, but this uses double complex arithmetic which might not be available on all platforms.

The row and column names of the result are taken from the column names of `a` and of `b` respectively. If `b` is missing the column names of the result are the row names of `a`. No check is made that the column names of `a` match the row names of `b`.

For back-compatibility `a` can be a (real) QR decomposition, although `qr.solve` should be called in that case. `qr.solve` can handle non-square systems.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

What happens if `a` and/or `b` contain missing, NaN or infinite values is platform-dependent, including on the version of LAPACK is in use.

`tol` is a tolerance for the (estimated 1-norm) ‘reciprocal condition number’: the check is skipped if `tol` $\leq$ 0.

For historical reasons, the default method accepts `a` as an object of class `"qr"` (with a warning) and passes it on to `solve.qr`.

Source

The default method is an interface to the LAPACK routines DGESV and ZGESV.

LAPACK is from <https://netlib.org/lapack/>.

## might not be supported on all platforms
try(solve(A))
```

sort	<i>Sorting or Ordering Vectors</i>
------	------------------------------------

Description

Sort (or *order*) a vector or factor (partially) into ascending or descending order. For ordering along more than one variable, e.g., for sorting data frames, see [order](#).

Usage

```
sort(x, decreasing = FALSE, ...)

## Default S3 method:
sort(x, decreasing = FALSE, na.last = NA, ...)

sort.int(x, partial = NULL, na.last = NA, decreasing = FALSE,
         method = c("auto", "shell", "quick", "radix"), index.return = FALSE)
```

Arguments

x	for <code>sort</code> an R object with a class or a numeric, complex, character or logical vector. For <code>sort.int</code> , a numeric, complex, character or logical vector, or a factor.
decreasing	logical. Should the sort be increasing or decreasing? Not available for partial sorting.
...	arguments to be passed to or from methods or (for the default methods and objects without a class) to <code>sort.int</code> .
na.last	for controlling the treatment of NAs. If <code>TRUE</code> , missing values in the data are put last; if <code>FALSE</code> , they are put first; if <code>NA</code> , they are removed.
partial	<code>NULL</code> or a vector of indices for partial sorting.
method	character string specifying the algorithm used. Not available for partial sorting. Can be abbreviated.
index.return	logical indicating if the ordering index vector should be returned as well. Supported by <code>method == "radix"</code> for any <code>na.last</code> mode and data type, and the other methods when <code>na.last = NA</code> (the default) and fully sorting non-factors.

Details

`sort` is a generic function for which methods can be written, and `sort.int` is the internal method which is compatible with S if only the first three arguments are used.

The default `sort` method makes use of `order` for classed objects, which in turn makes use of the generic function `xtfrm` (and can be slow unless a `xtfrm` method has been defined or `is.numeric(x)` is true).

Complex values are sorted first by the real part, then the imaginary part.

The "auto" method selects "radix" for short (less than 2^{31} elements) numeric vectors, integer vectors, logical vectors and factors; otherwise, "shell".

Except for method "radix", the sort order for character vectors will depend on the collating sequence of the locale in use: see [Comparison](#). The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors).

If `partial` is not `NULL`, it is taken to contain indices of elements of the result which are to be placed in their correct positions in the sorted array by partial sorting. For each of the result values in a specified position, any values smaller than that one are guaranteed to have a smaller index in the sorted array and any values which are greater are guaranteed to have a bigger index in the sorted array. (This is included for efficiency, and many of the options are not available for partial sorting. It is only substantially more efficient if `partial` has a handful of elements, and a full sort is done (a Quicksort if possible) if there are more than 10.) Names are discarded for partial sorting.

Method "shell" uses Shellsort (an $O(n^{4/3})$ variant from Sedgewick (1986). If `x` has names a stable modification is used, so ties are not reordered. (This only matters if names are present.)

Method "quick" uses the implementation of Hoare's Quicksort method from Singleton (1969) and is only available when `x` is numeric (double or integer) and `partial` is `NULL`. (For other types of `x` Shellsort is used, silently.) It is normally somewhat faster than Shellsort (perhaps 50% faster on vectors of length a million and twice as fast at a billion) but has poor performance in the rare worst case. (Peto's modification using a pseudo-random midpoint is used to make the worst case rarer.) This is not a stable sort, and ties may be reordered.

Method "radix" relies on simple hashing to scale time linearly with the input size, i.e., its asymptotic time complexity is $O(n)$. The specific variant and its implementation originated from the `data.table` package and are due to Matt Dowle and Arun Srinivasan. For small inputs (< 200), the implementation uses an insertion sort ($O(n^2)$) that operates in-place to avoid the allocation overhead of the radix sort. For integer vectors of range less than 100,000, it switches to a simpler and faster linear time counting sort. In all cases, the sort is stable; the order of ties is preserved. It is the default method for integer vectors and factors.

The "radix" method generally outperforms the other methods, especially for small integers. Compared to quick sort, it is slightly faster for vectors with large integer or real values (but unlike quick sort, radix is stable and supports all `na.last` options). The implementation is orders of magnitude faster than shell sort for character vectors, but collation *does not respect the locale* and so gives incorrect answers even in English locales.

However, there are some caveats for the radix sort:

- If `x` is a character vector, all elements must share the same encoding. Only UTF-8 (including ASCII) and Latin-1 encodings are supported. Collation follows that with `LC_COLLATE=C`, that is lexicographically byte-by-byte using numerical ordering of bytes.
- Long vectors (with 2^{31} or more elements) and complex vectors are not supported.

Value

For `sort`, the result depends on the S3 method which is dispatched. If `x` does not have a class `sort.int` is used and it description applies. For classed objects which do not have a specific

method the default method will be used and is equivalent to `x[order(x, ...)]`: this depends on the class having a suitable method for `[]` (and also that `order` will work, which requires a `xtfrm` method).

For `sort.int` the value is the sorted vector unless `index.return` is true, when the result is a list with components named `x` and `ix` containing the sorted numbers and the ordering index vector. In the latter case, if `method == "quick"` ties may be reversed in the ordering (unlike `sort.list`) as quicksort is not stable. For `method == "radix"`, `index.return` is supported for all `na.last` modes. The other methods only support `index.return` when `na.last` is NA. The index vector refers to element numbers *after removal of NAs*: see `order` if you want the original element numbers.

All attributes are removed from the return value (Becker, Chambers, and Wilks 1988, p. 146) except names, which are sorted. (If `partial` is specified even the names are removed.) Note that this means that the returned value has no class, except for factors and ordered factors (which are treated specially and whose result is transformed back to the original class).

stopifnot(identical(x1, x2))
stopifnot(identical(x1, x3))

## End(Not run)
```

sort_by

*Sorting Vectors or Data Frames by Other Vectors***Description**

Generic function to sort an object in the order determined by one or more other objects, typically vectors. A method is defined for data frames to sort its rows (typically by one or more columns), and the default method handles vector-like objects.

Usage

```
sort_by(x, y, ...)
```

```
## Default S3 method:
sort_by(x, y, ...)
```

```
## S3 method for class 'data.frame'
sort_by(x, y, ...)
```

Arguments

<code>x</code>	An object to be sorted, typically a vector or data frame.
<code>y</code>	Variables to sort by. For the default method, this can be a vector, or more generally any object that has a <code>xtfrm</code> method. For the <code>data.frame</code> method, typically a formula specifying the variables to sort by. The formula can take the forms <code>~ g</code> or <code>~ list(g)</code> to sort by the variable <code>g</code> , or more generally the forms <code>~ g1 + ... + gk</code> or <code>~ list(g1, ...,</code>

`gk`) to sort by the variables `g1, ..., gk`, using the later ones to resolve ties in the preceding ones. These variables are evaluated in the data frame `x` using the usual non-standard evaluation rules. If not a formula, `y = g` is equivalent to `y = ~ g` and `y = list(g1, ..., gk)` is equivalent to `y = ~ list(g1, ..., gk)`. However, non-standard evaluation in `x` is not done in this case.

... Additional arguments, typically passed on to `order`. These may include additional variables to sort by, as well as named arguments recognized by `order`.

Value

A sorted version of `x`. If `x` is a data frame, this means that the rows of `x` have been reordered to sort the variables specified in `y`.

See Also

`sort`, `order`.

Examples

```
mtcars$am
mtcars$mpg
with(mtcars, sort_by(mpg, am)) # group mpg by am

## data.frame method
sort_by(mtcars, runif(nrow(mtcars))) # random row permutation
sort_by(mtcars, list(mtcars$am, mtcars$mpg))

# formula interface
sort_by(mtcars, ~ am + mpg) |> subset(select = c(am, mpg))
sort_by.data.frame(mtcars, ~ list(am, -mpg)) |> subset(select = c(am, mpg))
```

source

Read R Code from a File, a Connection or Expressions

Description

`source` causes **R** to accept its input from the named file or URL or connection or expressions directly. Input is read and **parsed** from that file until the end of the file is reached, then the parsed expressions are evaluated sequentially in the chosen environment.

`withAutoprint(exprs)` is a wrapper for `source(exprs = exprs, ...)` with different defaults. Its main purpose is to evaluate and auto-print expressions as if in a top-level context, e.g. as in the **R** console.

Usage

```
source(file, local = FALSE, echo = verbose, print.eval = echo,
       exprs, spaced = use_file,
       verbose = getOption("verbose"),
       prompt.echo = getOption("prompt"),
       max.deparse.length = 150, width.cutoff = 60L,
       deparseCtrl = "showAttributes",
```

```

chdir = FALSE,
catch.aborts = FALSE,
encoding = getOption("encoding"),
continue.echo = getOption("continue"),
skip.echo = 0, keep.source = getOption("keep.source"))

withAutoprint(exprs, evaluated = FALSE, local = parent.frame(),
  print. = TRUE, echo = TRUE, max.deparse.length = Inf,
  width.cutoff = max(20, getOption("width")),
  deparseCtrl = c("keepInteger", "showAttributes", "keepNA"),
  skip.echo = 0,
  ...)

```

Arguments

<code>file</code>	a connection or a character string giving the pathname of the file or URL to read from. The <code>stdin()</code> connection reads from the console when interactive.
<code>local</code>	TRUE, FALSE or an environment, determining where the parsed expressions are evaluated. FALSE (the default) corresponds to the user's workspace (the global environment) and TRUE to the environment from which <code>source</code> is called.
<code>echo</code>	logical; if TRUE, each expression is printed after parsing, before evaluation.
<code>print.eval, print.</code>	logical; if TRUE, the result of <code>eval(i)</code> is printed for each expression <code>i</code> ; defaults to the value of <code>echo</code> .
<code>exprs</code>	for <code>source()</code> and <code>withAutoprint(*, evaluated=TRUE)</code> : <i>instead</i> of specifying <code>file</code> , an expression , call , or list of call 's, but <i>not</i> an unevaluated "expression". for <code>withAutoprint()</code> (with default <code>evaluated=FALSE</code>): one or more unevaluated "expressions".
<code>evaluated</code>	logical indicating that <code>exprs</code> is passed to <code>source(exprs=*)</code> and hence must be evaluated, i.e., a formal expression, call or list of calls .
<code>spaced</code>	logical indicating if newline (hence empty line) should be printed before each expression (when <code>echo = TRUE</code>).
<code>verbose</code>	if TRUE, more diagnostics (than just <code>echo = TRUE</code>) are printed during parsing and evaluation of input, including extra info for each expression.
<code>prompt.echo</code>	character; gives the prompt to be used if <code>echo = TRUE</code> .
<code>max.deparse.length</code>	integer; is used only if <code>echo</code> is TRUE and gives the maximal number of characters output for the <code>deparse</code> of a single expression.
<code>width.cutoff</code>	integer, passed to deparse() which is used (only) when there are no source references.
<code>deparseCtrl</code>	character vector, passed as control to deparse() , see also .deparseOpts . In R version <= 3.3.x, this was hardcoded to "showAttributes", which is the default currently; <code>deparseCtrl = "all"</code> may be preferable, when strict back compatibility is not of importance.
<code>chdir</code>	logical; if TRUE and <code>file</code> is a pathname, the R working directory is temporarily changed to the directory containing <code>file</code> for evaluating.
<code>catch.aborts</code>	logical indicating that "abort"ing errors should be caught.

<code>encoding</code>	character vector. The encoding(s) to be assumed when <code>file</code> is a character string: see file . A possible value is "unknown" when the encoding is guessed: see the 'Encodings' section.
<code>continue.echo</code>	character; gives the prompt to use on continuation lines if <code>echo = TRUE</code> .
<code>skip.echo</code>	integer; how many comment lines at the start of the file to skip if <code>echo = TRUE</code> .
<code>keep.source</code>	logical: should the source formatting be retained when echoing expressions, if possible?
<code>...</code>	(for <code>withAutoprint()</code>) further (non-file related) arguments to be passed to <code>source()</code> .

Details

Note that running code via `source` differs in a few respects from entering it at the R command line. Since expressions are not executed at the top level, auto-printing is not done. So you will need to include explicit `print` calls for things you want to be printed (and remember that this includes plotting by **lattice**, see “[Why do lattice/trellis graphics not work?](#)” in *R FAQ*). Since the complete file is parsed before any of it is run, syntax errors result in none of the code being run. If an error occurs in running a syntactically correct script, anything assigned into the workspace by code that has been run will be kept (just as from the command line), but diagnostic information such as `traceback()` will contain additional calls to `withVisible`.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic Mac OS) and map this to newline. The final line can be incomplete, that is missing the final end-of-line marker.

If `keep.source` is true (the default in interactive use), the source of functions is kept so they can be listed exactly as input.

Unlike input from a console, lines in the file or on a connection can contain an unlimited number of characters.

When `skip.echo > 0`, that many comment lines at the start of the file will not be echoed. This does not affect the execution of the code at all. If there are executable lines within the first `skip.echo` lines, echoing will start with the first of them.

If `echo` is true and a deparsed expression exceeds `max.deparse.length`, that many characters are output followed by `.... [TRUNCATED]`.

Encodings

By default the input is read and parsed in the current encoding of the R session. This is usually what is required, but occasionally re-encoding is needed, e.g. if a file from a UTF-8-using system is to be read on Windows (or *vice versa*).

The rest of this paragraph applies if `file` is an actual filename or URL (and not a connection). If `encoding = "unknown"`, an attempt is made to guess the encoding: the result of `localeToCharset()` is used as a guide. If `encoding` has two or more elements, they are tried in turn until the file/URL can be read without error in the trial encoding. If an actual encoding is specified (rather than the default or "unknown") in a Latin-1 or UTF-8 locale then character strings in the result will be translated to the current encoding and marked as such (see [Encoding](#)).

If `file` is a connection, it is not possible to re-encode the input inside `source`, and so the `encoding` argument is just used to mark character strings in the parsed input in Latin-1 and UTF-8 locales: see [parse](#).

Examples

```
someCond <- 7 > 6
## want an if-clause to behave "as top level" wrt auto-printing :
## (all should look "as if on top level", e.g. non-assignments should print:)
if(someCond) withAutoprint({
  x <- 1:12
  x-1
  (y <- (x-5)^2)
  z <- y
  z - 10
})

## If you want to source() a bunch of files, something like
## the following may be useful:
sourceDir <- function(path, trace = TRUE, ...) {
  op <- options(); on.exit(options(op)) # to reset after each
  for (nm in list.files(path, pattern = "[.]?[RrSsQq]?$")) {
    if(trace) cat(nm,":")
    source(file.path(path, nm), ...)
    if(trace) cat("\n")
    options(op)
  }
}

suppressWarnings( rm(x,y) ) # remove 'x' or 'y' from global env
withAutoprint({ x <- 1:2; cat("x=",x, "\n"); y <- x^2 })
## x and y now exist:
stopifnot(identical(x, 1:2), identical(y, x^2))

withAutoprint({ formals(sourceDir); body(sourceDir) },
               max.deparse.length = 20, verbose = TRUE)

## Continuing after (catchable) errors:
tc <- textConnection('1:3
2 + "3"
cat(" .. in spite of error: happily continuing! ..\n")
6*7')
r <- source(tc, catch.aborts = TRUE)
## Error in 2 + "3" ....
## .. in spite of error: happily continuing! ..
stopifnot(identical(r, list(value = 42, visible=TRUE)))
```

Description

Special mathematical functions related to the beta and gamma functions.

Usage

```
beta(a, b)
lbeta(a, b)

gamma(x)
lgamma(x)
psigamma(x, deriv = 0)
digamma(x)
trigamma(x)

choose(n, k)
lchoose(n, k)
factorial(x)
lfactorial(x)
```

Arguments

a, b	non-negative numeric vectors.
x, n	numeric vectors.
k, deriv	integer vectors.

Details

The functions `beta` and `lbeta` return the beta function and the natural logarithm of the beta function,

$$B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}.$$

The formal definition is

$$B(a, b) = \int_0^1 t^{a-1}(1-t)^{b-1} dt$$

(Abramowitz and Stegun 1972, page 258 in section 6.2.1). Note that it is only defined in $\mathbb{R}$ for non-negative a and b , and is infinite if either is zero.

The functions `gamma` and `lgamma` return the gamma function $\Gamma(x)$ and the natural logarithm of *the absolute value of* the gamma function. The gamma function is defined by (Abramowitz and Stegun 1972, page 255 in section 6.1.1)

$$\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt$$

for all $x > 0$, from which the recursions $\Gamma(x+1) = x\Gamma(x)$ and then $\Gamma(x+n) = (x+n-1)(x+n-2)\cdots x\Gamma(x)$ for all non-negative integers n . Solving for $\Gamma(x)$ and analytic continuation leads

to the expression for non-integer negative real numbers,

$$\Gamma(x) = \frac{\Gamma(x+n)}{(x+n-1)\cdots(x+1)x}, \quad n \in \mathbb{Z}^+, -n < x < 0,$$

see Abramowitz and Stegun (1972, equations 6.1.16 or 6.1.22 on page 256). The gamma function is not defined for zero and negative integers (when NaN is returned). There will be a warning on possible loss of precision for values which are too close (within about 10^{-8}) to a negative integer less than -10 .

`factorial(x)` ($x!$ for non-negative integer x) is defined to be `gamma(x+1)` and `lgamma` to be `lgamma(x+1)`.

The functions `digamma` and `trigamma` return the first and second derivatives of the logarithm of the gamma function. `psigamma(x, deriv)` (`deriv` ≥ 0) computes the `deriv`-th derivative of $\psi(x)$.

$$\text{digamma}(x) = \psi(x) = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)}$$

ψ and its derivatives, the `psigamma()` functions, are often called the ‘polygamma’ functions, e.g. in Abramowitz and Stegun (1972, page 260 in section 6.4.1); and higher derivatives (`deriv` = 2 : 4) have occasionally been called ‘tetragamma’, ‘pentagamma’, and ‘hexagamma’.

The functions `choose` and `lchoose` return binomial coefficients and the logarithms of their absolute values. Note that `choose(n, k)` is defined for all real numbers n and integer k . For $k \geq 1$ it is defined as $n(n-1)\cdots(n-k+1)/k!$, as 1 for $k = 0$ and as 0 for negative k . Non-integer values of k are rounded to an integer, with a warning.

`choose(*, k)` uses direct arithmetic (instead of `[1]gamma` calls) for small k , for speed and accuracy reasons. Note the function `combn` (package **utils**) for enumeration of all possible combinations.

The `gamma`, `lgamma`, `digamma` and `trigamma` functions are **internal generic primitive** functions: methods can be defined for them individually or via the **Math** group generic.

Source

`gamma`, `lgamma`, `beta` and `lbeta` are based on C translations of Fortran subroutines by W. Fullerton of Los Alamos Scientific Laboratory (now available as part of SLATEC).

`digamma`, `trigamma` and `psigamma` for $x \geq 0$ are based on Amos (1983). For $x < 0$ and `deriv` ≤ 5 , the reflection formula (6.4.7) of Abramowitz and Stegun is used.

```

split

Divide into Groups and Reassemble

Description

`split` divides the data in the vector `x` into the groups defined by `f`. The replacement forms replace values corresponding to such a division. `unsplit` reverses the effect of `split`.

Usage

```

split(x, f, drop = FALSE, ...)
## Default S3 method:
split(x, f, drop = FALSE, sep = ".", lex.order = FALSE, ...)

split(x, f, drop = FALSE, ...) <- value
unsplit(value, f, drop = FALSE)

```

Arguments

- | | |
|------------------------|--|
| <code>x</code> | vector or data frame containing values to be divided into groups. |
| <code>f</code> | a ‘factor’ in the sense that <code>as.factor(f)</code> defines the grouping, or a list of such factors in which case their interaction is used for the grouping. If <code>x</code> is a data frame, <code>f</code> can also be a formula of the form <code>~ g</code> to split by the variable <code>g</code> , or more generally of the form <code>~ g1 + ... + gk</code> to split by the interaction of the variables <code>g1, ..., gk</code> , where these variables are evaluated in the data frame <code>x</code> using the usual non-standard evaluation rules. |
| <code>drop</code> | logical indicating if levels that do not occur should be dropped (if <code>f</code> is a factor or a list). |
| <code>value</code> | a list of vectors or data frames compatible with a splitting of <code>x</code> . Recycling applies if the lengths do not match. |
| <code>sep</code> | character string, passed to <code>interaction</code> in the case where <code>f</code> is a list. |
| <code>lex.order</code> | logical, passed to <code>interaction</code> when <code>f</code> is a list. |
| <code>...</code> | further potential arguments passed to methods. |

Details

`split` and `split<-` are generic functions with default and `data.frame` methods. The data frame method can also be used to split a matrix into a list of matrices, and the replacement form likewise, provided they are invoked explicitly.

`unsplit` works with lists of vectors or data frames (assumed to have compatible structure, as if created by `split`). It puts elements or rows back in the positions given by `f`. In the data frame case, row names are obtained by unsplitting the row name vectors from the elements of `value`.

`f` is recycled as necessary and if the length of `x` is not a multiple of the length of `f` a warning is printed.

Any missing values in `f` are dropped together with the corresponding values of `x`.

The default method calls `interaction` when `f` is a `list`. If the levels of the factors contain `'.'` the factors may not be split as expected, unless `sep` is set to string not present in the factor `levels`.

Value

The value returned from `split` is a list of vectors containing the values for the groups. The components of the list are named by the levels of `f` (after converting to a factor, or if already a factor and `drop = TRUE`, dropping unused levels).

The replacement forms return their right hand side. `unsplit` returns a vector or data frame for which `split(x, f)` equals `value`

head(aq2)
with(aq2, tapply(Oz.Z, Month, sd, na.rm = TRUE))

### Split a matrix into a list by columns
ma <- cbind(x = 1:10, y = (-4:5)^2)
split(ma, col(ma))

split(1:10, 1:2)

```

sprintf

Use C-style String Formatting Commands

Description

A wrapper for the C function `sprintf`, that returns a character vector containing a formatted combination of text and variable values.

Usage

```

sprintf(fmt, ...)
gettextf(fmt, ..., domain = NULL, trim = TRUE)

```

Arguments

<code>fmt</code>	a character vector of format strings, each of up to 8192 bytes.
<code>...</code>	values to be passed into <code>fmt</code> . Only logical, integer, real and character vectors are supported, but some coercion will be done: see the ‘Details’ section. Up to 100.
<code>trim, domain</code>	see gettext .

Details

`sprintf` is a wrapper for the system `sprintf` C-library function. Attempts are made to check that the mode of the values passed match the format supplied, and R’s special values (NA, Inf, -Inf and NaN) are handled correctly.

`gettextf` is a convenience function which provides C-style string formatting with possible translation of the format string.

The arguments (including `fmt`) are recycled if possible a whole number of times to the length of the longest, and then the formatting is done in parallel. Zero-length arguments are allowed and will give a zero-length result. All arguments are evaluated even if unused, and hence some types (e.g., "symbol" or "language", see `typeof`) are not allowed. Arguments unused by `fmt` result in a warning. (The format `% .0s` can be used to "skip" an argument.)

The following is abstracted from Kernighan and Ritchie (1988): however the actual implementation will follow the C99 standard and fine details (especially the behaviour under user error) may depend on the platform. References to numbered arguments come from POSIX.

The string `fmt` contains normal characters, which are passed through to the output string, and also conversion specifications which operate on the arguments provided through `...`. The allowed conversion specifications start with a `%` and end with one of the letters in the set `aA difeEgGosxX%`. These letters denote the following types:

- `d, i, o, x, X` Integer value, `o` being octal, `x` and `X` being hexadecimal (using the same case for `a-f` as the code). Numeric variables with exactly integer values will be coerced to integer. Formats `d` and `i` can also be used for logical variables, which will be converted to 0, 1 or NA.
- `f` Double precision value, in "fixed point" decimal notation of the form `"[-]mmm.ddd"`. The number of decimal places ("d") is specified by the precision: the default is 6; a precision of 0 suppresses the decimal point. Non-finite values are converted to NA, NaN or (perhaps a sign followed by) `Inf`.
- `e, E` Double precision value, in "exponential" decimal notation of the form `[-]m.ddde[+-]xx` or `[-]m.dddE[+-]xx`.
- `g, G` Double precision value, in `%e` or `%E` format if the exponent is less than -4 or greater than or equal to the precision, and `%f` format otherwise. (The precision (default 6) specifies the number of *significant* digits here, whereas in `%f`, `%e`, it is the number of digits after the decimal point.)
- `a, A` Double precision value, in binary notation of the form `[-]0xh.hhhp[+-]d`. This is a binary fraction expressed in hex multiplied by a (decimal) power of 2. The number of hex digits after the decimal point is specified by the precision: the default is enough digits to represent exactly the internal binary representation. Non-finite values are converted to NA, NaN or (perhaps a sign followed by) `Inf`. Format `%a` uses lower-case for `x`, `p` and the hex values: format `%A` uses upper-case.
 This should be supported on all platforms as it is a feature of C99. The format is not uniquely defined: although it would be possible to make the leading `h` always zero or one, this is not always done. Most systems will suppress trailing zeros, but a few do not. On a well-written platform, for normal numbers there will be a leading one before the decimal point plus (by default) 13 hexadecimal digits, hence 53 bits. The treatment of denormalized (aka 'subnormal') numbers is very platform-dependent.
- `s` Character string. Character NAs are converted to "NA".
- `%` Literal `%` (none of the extra formatting characters given below are permitted in this case).

Conversion by `as.character` is used for non-character arguments with `s` and by `as.double` for non-double arguments with `f`, `e`, `E`, `g`, `G`. NB: the length is determined before conversion, so do not rely on the internal coercion if this would change the length. The coercion is done only once, so if `length(fmt) > 1` then all elements must expect the same types of arguments.

In addition, between the initial `%` and the terminating conversion character there may be, in any order:

`m.n` Two numbers separated by a period, denoting the field width (`m`) and the precision (`n`).

- Left adjustment of converted argument in its field.

- + Always print number with sign: by default only negative numbers are printed with a sign.

a space Prefix a space if the first character is not a sign.

`0` For numbers, pad to the field width with leading zeros. For characters, this zero-pads on some platforms and is ignored on others.

`#` specifies “alternate output” for numbers, its action depending on the type: For `x` or `X`, `0x` or `0X` will be prefixed to a non-zero result. For `e`, `E`, `f`, `g` and `G`, the output will always have a decimal point; for `g` and `G`, trailing zeros will not be removed.

Further, immediately after `%` may come `1$` to `99$` to refer to a numbered argument: this allows arguments to be referenced out of order and is mainly intended for translators of error messages. If this is done it is best if all formats are numbered: if not the unnumbered ones process the arguments in order. See the examples. This notation allows arguments to be used more than once, in which case they must be used as the same type (integer, double or character).

A field width or precision (but not both) may be indicated by an asterisk `*`: in this case an argument specifies the desired number. A negative field width is taken as a `'-'` flag followed by a positive field width. A negative precision is treated as if the precision were omitted. The argument should be integer, but a double argument will be coerced to integer.

There is a limit of 8192 bytes on elements of `fmt`, and on strings included from a single `%letter` conversion specification.

Field widths and precisions of `%s` conversions are interpreted as bytes, not characters, as described in the C standard.

The C doubles used for R numerical vectors have signed zeros, which `sprintf` may output as `-0`, `-0.000 ...`.

Value

A character vector of length that of the longest input. If any element of `fmt` or any character argument is declared as UTF-8, the element of the result will be in UTF-8 and have the encoding declared as UTF-8. Otherwise it will be in the current locale’s encoding.

Warning

The format string is passed down the OS’s `sprintf` function, and incorrect formats can cause the latter to crash the R process. R does perform sanity checks on the format, but not all possible user errors on all platforms have been tested, and some might be terminal.

The behaviour on inputs not documented here is ‘undefined’, which means it is allowed to differ by platform.

[gettext](#) for the mechanisms for the automated translation of text.

Examples

```
## be careful with the format: most things in R are floats
## only integer-valued reals get coerced to integer.

sprintf("%s is %f feet tall\n", "Sven", 7.1)      # OK
try(sprintf("%s is %i feet tall\n", "Sven", 7.1)) # not OK
  sprintf("%s is %i feet tall\n", "Sven", 7 )    # OK

## use a literal % :

sprintf("%.0f%% said yes (out of a sample of size %.0f)", 66.666, 3)

## various formats of pi :

sprintf("%f", pi)
sprintf("%.3f", pi)
sprintf("%1.0f", pi)
sprintf("%5.1f", pi)
sprintf("%05.1f", pi)
sprintf("%+f", pi)
sprintf("% f", pi)
sprintf("%-10f", pi) # left justified
sprintf("%e", pi)
sprintf("%E", pi)
sprintf("%g", pi)
sprintf("%g", 1e6 * pi) # -> exponential
sprintf("%.9g", 1e6 * pi) # -> "fixed"
sprintf("%G", 1e-6 * pi)

## no truncation:
sprintf("%1.f", 101)

## re-use one argument three times, show difference between %x and %X
xx <- sprintf("%1$d %1$x %1$X", 0:15)
xx <- matrix(xx, dimnames = list(rep("", 16), "%d%x%X"))
noquote(format(xx, justify = "right"))

## More sophisticated:

sprintf("min 10-char string '%10s'",
  c("a", "ABC", "and an even longer one"))
```

```

n <- 1:18
sprintf(paste0("e with %2d digits = %.", n, "g"), n, exp(1))

## Platform-dependent bad example: may pad with spaces or zeroes
sprintf("%09s", month.name)

## Using arguments out of order
sprintf("second %2$1.0f, first %1$5.2f, third %3$1.0f", pi, 2, 3)

## Using asterisk for width or precision
sprintf("precision %.*f, width '%*.3f'", 3, pi, 8, pi)

## Asterisk and argument re-use, 'e' example reiterated:
sprintf("e with %1$2d digits = %2$.*1$g", n, exp(1))

## re-cycle arguments
sprintf("%s %d", "test", 1:3)

## binary output showing rounding/representation errors
x <- seq(0, 1.0, 0.1); y <- c(0,.1,.2,.3,.4,.5,.6,.7,.8,.9,1)
cbind(x, sprintf("%a", x), sprintf("%a", y))

```

sQuote

Quote Text

Description

Single or double quote text by combining with appropriate single or double left and right quotation marks.

Usage

```

sQuote(x, q = getOption("useFancyQuotes"))
dQuote(x, q = getOption("useFancyQuotes"))

```

Arguments

x	an R object, to be coerced to a character vector.
q	the kind of quotes to be used, see ‘Details’.

Details

The purpose of the functions is to provide a simple means of markup for quoting text to be used in the R output, e.g., in warnings or error messages.

The choice of the appropriate quotation marks depends on both the locale and the available character sets. Older Unix/X11 fonts displayed the grave accent (ASCII code 0x60) and the apostrophe (0x27) in a way that they could also be used as matching open and close single quotation marks. Using modern fonts, or non-Unix systems, these characters no longer produce matching glyphs. Unicode provides left and right single quotation mark characters (U+2018 and U+2019); if Unicode markup cannot be assumed to be available, it seems good practice to use the apostrophe as a non-directional single quotation mark.

Similarly, Unicode has left and right double quotation mark characters (U+201C and U+201D); if only ASCII's typewriter characteristics can be employed, then the ASCII quotation mark (0x22) should be used as both the left and right double quotation mark.

Some other locales also have the directional quotation marks, notably on Windows. TeX uses grave and apostrophe for the directional single quotation marks, and doubled grave and doubled apostrophe for the directional double quotation marks.

What rendering is used depends on `q` which by default depends on the `options` setting for `useFancyQuotes`. If this is `FALSE` then the unidirectional ASCII quotation style is used. If this is `TRUE` (the default), Unicode directional quotes are used where available (currently, UTF-8 locales on Unix-alikes and all Windows locales except C): if set to `"UTF-8"` UTF-8 markup is used (whatever the current locale). If set to `"TeX"`, TeX-style markup is used. Finally, if this is set to a character vector of length four, the first two entries are used for beginning and ending single quotes and the second two for beginning and ending double quotes: this can be used to implement non-English quoting conventions such as the use of guillemets.

Where fancy quotes are used, you should be aware that they may not be rendered correctly as not all fonts include the requisite glyphs: for example some have directional single quotes but not directional double quotes.

Value

A character vector of the same length as `x` (after any coercion) in the current locale's encoding.

srcfile

References to Source Files and Code

Description

These functions are for working with source files and more generally with “source references” (“srcref”), i.e., references to source code. The resulting data is used for printing and source level debugging, and is typically available in interactive R sessions, namely when `options(keep.source = TRUE)`.

Usage

```
srcfile(filename, encoding = getOption("encoding"), Enc = "unknown")
srcfilecopy(filename, lines, timestamp = Sys.time(), isFile = FALSE)
srcfilealias(filename, srcfile)
getSrcLines(srcfile, first, last)
srcref(srcfile, lloc)
## S3 method for class 'srcfile'
print(x, ...)
## S3 method for class 'srcfile'
summary(object, ...)
## S3 method for class 'srcfile'
open(con, line, ...)
## S3 method for class 'srcfile'
close(con, ...)
## S3 method for class 'srcref'
print(x, useSource = TRUE, ...)
## S3 method for class 'srcref'
summary(object, useSource = FALSE, ...)
## S3 method for class 'srcref'
as.character(x, useSource = TRUE, to = x, ...)
.isOpen(srcfile)
```

Arguments

filename	The name of a file.
encoding	The character encoding to assume for the file.
Enc	The encoding with which to make strings: see the encoding argument of parse .
lines	A character vector of source lines. Other R objects will be coerced to character.
timestamp	The timestamp to use on a copy of a file.
isFile	Is this <code>srcfilecopy</code> known to come from a file system file?
srcfile	A <code>srcfile</code> object.
first, last, line	Line numbers.
lloc	A vector of four, six or eight values giving a source location; see ‘Details’.

<code>x, object, con</code>	An object of the appropriate class.
<code>useSource</code>	Whether to read the <code>srcfile</code> to obtain the text of a <code>srcref</code> .
<code>to</code>	An optional second <code>srcref</code> object to mark the end of the character range.
<code>...</code>	Additional arguments to the methods; these will be ignored.

Details

These functions and classes handle source code references.

The `srcfile` function produces an object of class `srcfile`, which contains the name and directory of a source code file, along with its timestamp, for use in source level debugging (not yet implemented) and source echoing. The encoding of the file is saved; see [file](#) for a discussion of encodings, and [iconvlist](#) for a list of allowable encodings on your platform.

The `srcfilecopy` function produces an object of the descendant class `srcfilecopy`, which saves the source lines in a character vector. It copies the value of the `isFile` argument, to help debuggers identify whether this text comes from a real file in the file system.

The `srcfilealias` function produces an object of the descendant class `srcfilealias`, which gives an alternate name to another `srcfile`. This is produced by the parser when a `#line` directive is used.

The `getSrcLines` function reads the specified lines from `srcfile`.

The `srcref` function produces an object of class `srcref`, which describes a range of characters in a `srcfile`. The `lloc` value gives the following values:

```
c(first_line, first_byte, last_line, last_byte, first_column,
   last_column, first_parsed, last_parsed)
```

Bytes (elements 2, 4) and columns (elements 5, 6) may be different due to multibyte characters. If only four values are given, the columns and bytes are assumed to match. Lines (elements 1, 3) and parsed lines (elements 7, 8) may differ if a `#line` directive is used in code: the former will respect the directive, the latter will just count lines. If only 4 or 6 elements are given, the parsed lines will be assumed to match the lines.

Methods are defined for `print`, `summary`, `open`, and `close` for classes `srcfile` and `srcfilecopy`. The `open` method opens its internal [file](#) connection at a particular line; if it was already open, it will be repositioned to that line.

Methods are defined for `print`, `summary` and `as.character` for class `srcref`. The `as.character` method will read the associated source file to obtain the text corresponding to the reference. If the `to` argument is given, it should be a second `srcref` that follows the first, in the same file; they will be treated as one reference to the whole range. The exact behaviour depends on the class of the source file. If the source file inherits from class `srcfilecopy`, the lines are taken from the saved copy using the “parsed” line counts. If not, an attempt is made to read the file, and the original line numbers of the `srcref` record (i.e., elements 1 and 3) are used. If an error occurs (e.g., the file no longer exists), text like `<srcref: "file" chars 1:1 to 2:10>` will be returned instead, indicating the `line:column` ranges of the first and last character. The `summary` method defaults to this type of display.

Lists of `srcref` objects may be attached to expressions as the `"srcref"` attribute. (The list of `srcref` objects should be the same length as the expression.) By default, expressions are printed by `print.default` using the associated `srcref`. To see deparsed code instead, call `print` with argument `useSource = FALSE`. If a `srcref` object is printed with `useSource = FALSE`, the `<srcref: ....>` record will be printed.

`.isOpen` is intended for internal use: it checks whether the connection associated with a `srcfile` object is open.

Value

`srcfile` returns a `srcfile` object.

`srcfilecopy` returns a `srcfilecopy` object.

`getSrcLines` returns a character vector of source code lines.

`srcref` returns a `srcref` object.

Author(s)

Duncan Murdoch

See Also

[getSrcFilename](#) for extracting information from a source reference, or [removeSource](#) to remove it from a language object or a (non-primitive) function (aka ‘closure’).

Examples

```
src <- srcfile(system.file("DESCRIPTION", package = "base"))
summary(src)
getSrcLines(src, 1, 4)
ref <- srcref(src, c(1, 1, 2, 1000))
ref
print(ref, useSource = FALSE)
```

StackOverflows

Stack Overflow Errors

Description

Errors signaled by R when stacks used in evaluation overflow.

Details

R uses several stacks in evaluating expressions: the C stack, the pointer protection stack, and the node stack used by the byte code engine. In addition, the number of nested R expressions currently under evaluation is limited by the value set as `options("expressions")`. Overflowing these stacks or limits signals an error that inherits from classes `stackOverflowError`, `error`, and `condition`.

The specific classes signaled are:

- `CStackOverflowError`: Signaled when the C stack overflows. The `usage` field of the error object contains the current stack usage.
- `protectStackOverflowError`: Signaled when the pointer protection stack overflows.
- `nodeStackOverflowError`: Signaled when the node stack used by the byte code engine overflows.
- `expressionStackOverflowError`: Signaled when the the evaluation depth, the number of nested R expressions currently under evaluation, exceeds the limit set by `options("expressions")`

Stack overflow errors can be caught and handled by exiting handlers established with `tryCatch()`. Calling handlers established by `withCallingHandlers()` may fail since there may not be enough stack space to run the handler. In this case the next available exiting handler will be run, or error handling will fall back to the default handler. Default handlers set by `tryCatch("error")` may also fail to run in a stack overflow situation.

See Also

`Cstack_info` for information on the environment and the evaluation depth limit.

`Memory` and `options` for information on the protection stack.

standardGeneric	<i>Formal Method System – Dispatching S4 Methods</i>
-----------------	--

Description

The function `standardGeneric` initiates dispatch of S4 methods: see the references and the documentation of the **methods** package. Usually, calls to this function are generated automatically and not explicitly by the programmer.

Usage

```
standardGeneric(f, fdef)
```

Arguments

<code>f</code>	The name of the generic.
<code>fdef</code>	The generic function definition. Never passed when defining a new generic.

Details

`standardGeneric` dispatches the method defined for a generic function named `f`, using the actual arguments in the frame from which it is called.

The argument `fdef` is inserted (automatically) when dispatching methods for a primitive function. If present, it must always be the function definition for the corresponding generic. Don't insert this argument by hand, as there is no validity checking and miss-specifying the function definition will cause certain failure.

For more, use the **methods** package, and see the documentation in [GenericFunctions](#).

startsWith*Does String Start or End With Another String?*

Description

Determines if entries of `x` start or end with string (entries of) `prefix` or `suffix` respectively, where strings are recycled to common lengths.

Usage

```
startsWith(x, prefix)
endsWith(x, suffix)
```

Arguments

`x` [character](#) vector whose “starts” or “ends” are considered.
`prefix, suffix` [character](#) vector, typically of length one, i.e., a string.

Details

`startsWith()` is equivalent to but much faster than

```
substring(x, 1, nchar(prefix)) == prefix
```

or also

```
grepl("^<prefix>", x)
```

where `prefix` is not to contain special regular expression characters (and for `grepl`, `x` does not contain missing values, see below).

The code has an optimized branch for the most common usage in which `prefix` or `suffix` is of length one, and is further optimized in a UTF-8 or 8-byte locale if that is an ASCII string.

Value

A [logical](#) vector, of “common length” of `x` and `prefix` (or `suffix`), i.e., of the longer of the two lengths unless one of them is zero when the result is also of zero length. A shorter input is recycled to the output length.

See Also

[grepl](#), [substring](#); the partial string matching functions [charmatch](#) and [pmatch](#) solve a different task.

Examples

```

startsWith(search(), "package:") # typically at least two FALSE, nowadays often three

x1 <- c("Foobar", "bla bla", "something", "another", "blu", "brown",
       "blau blüht der Enzian") # non-ASCII
x2 <- cbind(
  startsWith(x1, "b"),
  startsWith(x1, "bl"),
  startsWith(x1, "bla"),
  endsWith(x1, "n"),
  endsWith(x1, "an"))
rownames(x2) <- x1; colnames(x2) <- c("b", "bl", "bla", "n", "an")
x2

## Non-equivalence in case of missing values in 'x', see Details:
x <- c("all", "but", NA_character_)
cbind(startsWith(x, "a"),
      substring(x, 1L, 1L) == "a",
      grepl("^a", x))

```

Description

In R, the startup mechanism is as follows.

Unless ‘`--no-envir`’ was given on the command line, R searches for site and user files to process for setting environment variables. The name of the site file is the one pointed to by the environment variable `R_ENVIRON`; if this is unset, ‘`R_HOME/etc/Renviron.site`’ is used (if it exists, which it does not in a ‘factory-fresh’ installation). The name of the user file can be specified by the `R_ENVIRON_USER` environment variable; if this is unset, the files searched for are ‘`.Renviron`’ in the current or in the user’s home directory (in that order). See ‘Details’ for how the files are read.

Then R searches for the site-wide startup profile file of R code unless the command line option ‘`--no-site-file`’ was given. The path of this file is taken from the value of the `R_PROFILE` environment variable (after [tilde expansion](#)). If this variable is unset, the default is ‘`R_HOME/etc/Rprofile.site`’, which is used if it exists (which it does not in a ‘factory-fresh’ installation). This code is sourced into the workspace (global environment). Users need to be careful not to unintentionally create objects in the workspace, and it is normally advisable to use `local` if code needs to be executed: see the examples. `.Library.site` may be assigned to and the assignment will effectively modify the value of the variable in the base namespace where `.libPaths()` finds it. One may also assign to `.First` and `.Last`, but assigning to other variables in the execution environment is not recommended and does not work in some older versions of R.

Then, unless ‘`--no-init-file`’ was given, R searches for a user profile, a file of R code. The path of this file can be specified by the `R_PROFILE_USER` environment variable (and [tilde expansion](#) will be performed). If this is unset, a file called ‘`.Rprofile`’ is searched for in the current directory or in the user’s home directory (in that order). The user profile file is sourced into the workspace.

Note that when the site and user profile files are sourced only the **base** package is loaded, so objects in other packages need to be referred to by e.g. `utils::dump.frames` or after explicitly loading the package concerned.

R then loads a saved image of the user workspace from `‘.RData’` in the current directory if there is one (unless `‘--no-restore-data’` or `‘--no-restore’` was specified on the command line).

Next, if a function `.First` is found on the search path, it is executed as `.First()`. Finally, function `.First.sys()` in the **base** package is run. This calls `require` to attach the default packages specified by `options("defaultPackages")`. If the **methods** package is included, this will have been attached earlier (by function `.OptRequireMethods()`) so that namespace initializations such as those from the user workspace will proceed correctly.

A function `.First` (and `.Last`) can be defined in appropriate `‘.Rprofile’` or `‘Rprofile.site’` files or have been saved in `‘.RData’`. If you want a different set of packages than the default ones when you start, insert a call to `options` in the `‘.Rprofile’` or `‘Rprofile.site’` file. For example, `options(defaultPackages = character())` will attach no extra packages on startup (only the **base** package) (or set `R_DEFAULT_PACKAGES=NULL` as an environment variable before running R). Using `options(defaultPackages = "")` or `R_DEFAULT_PACKAGES=""` enforces the R *system* default.

On front-ends which support it, the commands history is read from the file specified by the environment variable `R_HISTFILE` (default `‘.Rhistory’` in the current directory) unless `‘--no-restore-history’` or `‘--no-restore’` was specified.

The command-line option `‘--vanilla’` implies `‘--no-site-file’`, `‘--no-init-file’`, `‘--no-envIRON’` and (except for R CMD) `‘--no-restore’`

Details

Note that there are two sorts of files used in startup: *environment files* which contain lists of environment variables to be set, and *profile files* which contain R code.

Lines in a site or user environment file should be either comment lines starting with `#`, or lines of the form `name=value`. The latter sets the environmental variable `name` to `value`, overriding an existing value. If `value` contains an expression of the form `${foo-bar}`, the value is that of the environmental variable `foo` if that is set, otherwise `bar`. For `${foo:-bar}`, the value is that of `foo` if that is set to a non-empty value, otherwise `bar`. (If it is of the form `${foo}`, the default is `"."`.) This construction can be nested, so `bar` can be of the same form (as in `${foo-${bar-blah}}`). Note that the braces are essential: for example `$HOME` will not be interpreted.

Leading and trailing white space in `value` are stripped. `value` is then processed in a similar way to a Unix shell: in particular (single or double) quotes not preceded by backslash are removed and backslashes are removed except inside such quotes.

For readability and future compatibility it is recommended to only use constructs that have the same behavior as in a Unix shell. Hence, expansions of variables should be in double quotes (e.g. `"${HOME}"`, in case they may contain a backslash) and literals including a backslash should be in single quotes. If a variable value may end in a backslash, such as `PATH` on Windows, it may be necessary to protect the following quote from it, e.g. `"${PATH}/"`. It is recommended to use forward slashes instead of backslashes. It is ok to mix text in single and double quotes, see examples below.

On systems with sub-architectures (mainly Windows), the files `‘RenvIRON.site’` and `‘Rprofile.site’` are looked for first in architecture-specific directories, e.g. `‘R\_HOME/etc/i386/RenvIRON.site’`. And e.g. `‘.RenvIRON.i386’` will be used in preference to `‘.RenvIRON’`.

There is a 100,000 byte limit on the length of a line (after expansions) in environment files.

Note

It is not intended that there be interaction with the user during startup code. Attempting to do so can crash the R process.

On Unix versions of R there is also a file '[R_HOME](#)/etc/Renviron' which is read very early in the start-up processing. It contains environment variables set by R in the configure process. Values in that file can be overridden in site or user environment files: do not change '[R_HOME](#)/etc/Renviron' itself. Note that this is distinct from '[R_HOME](#)/etc/Renviron.site'.

Command-line options may well not apply to alternative front-ends: they do not apply to R.app on macOS.

R CMD check and R CMD build do not always read the standard startup files, but they do always read specific 'Renviron' files. The location of these can be controlled by the environment variables R_CHECK_ENVIRON and R_BUILD_ENVIRON. If these are set their value is used as the path for the 'Renviron' file; otherwise, files '~/.R/check.Renviron' or '~/.R/build.Renviron' or sub-architecture-specific versions are employed.

If you want '~/.Renviron' or '~/.Rprofile' to be ignored by child R processes (such as those run by R CMD check and R CMD build), set the appropriate environment variable R_ENVIRON_USER or R_PROFILE_USER to (if possible, which it is not on Windows) "" or to the name of a non-existent file.

Examples

```
## Not run:
## Example ~/.Renviron on Unix
R_LIBS=~ /R/library
PAGER=/usr/local/bin/less

## Example .Renviron on Windows
R_LIBS=C:/R/library
MY_TCLTK="c:/Program Files/Tcl/bin"
# Variable expansion in double quotes, string literals with backslashes in
# single quotes.
R_LIBS_USER="${APPDATA}"'\R-library'

## Example of setting R_DEFAULT_PACKAGES (from R CMD check)
R_DEFAULT_PACKAGES='utils,grDevices,graphics,stats'
# this loads the packages in the order given, so they appear on
# the search path in reverse order.
```

```
## Example of .Rprofile
options(width=65, digits=5)
options(show.signif.stars=FALSE)
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::ps.options(horizontal=FALSE))
set.seed(1234)
.First <- function() cat("\n  Welcome to R!\n\n")
.Last <- function()  cat("\n  Goodbye!\n\n")

## Example of Rprofile.site
local({
  # add MASS to the default packages, set a CRAN mirror
  old <- getOption("defaultPackages"); r <- getOption("repos")
  r["CRAN"] <- "http://my.local.cran"
  options(defaultPackages = c(old, "MASS"), repos = r)
  ## (for Unix terminal users) set the width from COLUMNS if set
  cols <- Sys.getenv("COLUMNS")
  if(nzchar(cols)) options(width = as.integer(cols))
  # interactive sessions get a fortune cookie (needs fortunes package)
  if (interactive())
    fortunes::fortune()
})

## if .Renviron contains
FOOBAR="coo\bar"doh\ex"abc\"def'"

## then we get
# > cat(Sys.getenv("FOOBAR"), "\n")
# coo\bardoh\exabc"def'"

## End(Not run)
```

stop

Stop Function Execution

Description

stop stops execution of the current expression and executes an error action.

geterrmessage gives the last error message.

Usage

```
stop(..., call. = TRUE, domain = NULL)
geterrmessage()
```

Arguments

...	zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
call.	logical, indicating if the call should become part of the error message.
domain	see gettext . If NA, messages will not be translated.

Details

The error action is controlled by error handlers established within the executing code and by the current default error handler set by `options(error=)`. The error is first signaled as if using `signalCondition()`. If there are no handlers or if all handlers return, then the error message is printed (if `options("show.error.messages")` is true) and the default error handler is used. The default behaviour (the NULL error-handler) in interactive use is to return to the top level prompt or the top level browser, and in non-interactive use to (effectively) call `q("no", status = 1, runLast = FALSE)` unless `getOption("catch.script.errors")` is true.

The default handler stores the error message in a buffer; it can be retrieved by `geterrmessage()`. It also stores a trace of the call stack that can be retrieved by `traceback()`.

Errors will be truncated to `getOption("warning.length")` characters, default 1000.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a warning.

Value

`geterrmessage` gives the last error message, as a character string ending in `"\n"`.

Note

Use `domain = NA` whenever . . . contain a result from `gettextf()` as that is translated already.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`warning`, `try` to catch errors and retry, and `options` for setting error handlers. `stopifnot` for validity testing. `tryCatch` and `withCallingHandlers` can be used to establish custom handlers while executing an expression.

`gettext` for the mechanisms for the automated translation of messages.

Examples

```
iter <- 12
try(if(iter > 10) stop("too many iterations"))

tst1 <- function(...) stop("dummy error")
try(tst1(1:10, long, calling, expression))

tst2 <- function(...) stop("dummy error", call. = FALSE)
try(tst2(1:10, longcalling, expression, but.not.seen.in.Error))
```

stopifnot

Ensure the Truth of R Expressions

Description

If any of the expressions (in `...` or `exprs`) are not `all TRUE`, `stop` is called, producing an error message indicating the *first* expression which was not (`all`) true.

Usage

```
stopifnot(..., exprs, exprObject, local = TRUE)
```

Arguments

`...,exprs` any number of R expressions, which should each evaluate to (a logical vector of all) `TRUE`. Use *either* `...` or `exprs`, the latter typically an unevaluated expression of the form

```
{
  expr1
  expr2
  ....
}
```

Note that e.g., positive numbers are *not* `TRUE`, even when they are coerced to `TRUE`, e.g., inside `if(.)` or in arithmetic computations in R.

If names are provided to `...`, they will be used in lieu of the default error message.

`exprObject` alternative to `exprs` or `...`: an ‘expression-like’ object, typically an `expression`, but also a `call`, a `name`, or atomic constant such as `TRUE`.

`local` (only when `exprs` is used:) indicates the `environment` in which the expressions should be evaluated; by default the one from where `stopifnot()` has been called.

Details

This function is intended for use in regression tests or also argument checking of functions, in particular to make them easier to read.

`stopifnot(A, B)` or equivalently `stopifnot(exprs= {A ; B})` are conceptually equivalent to

```
{ if(any(is.na(A)) || !all(A)) stop(...);
  if(any(is.na(B)) || !all(B)) stop(...) }
```

Since R version 3.6.0, `stopifnot()` no longer handles potential errors or warnings (by `tryCatch()` etc) for each single expression and may use `sys.call(n)` to get a meaningful and short error message in case an expression did not evaluate to all `TRUE`. This provides considerably less overhead.

Since R version 3.5.0, expressions *are* evaluated sequentially, and hence evaluation stops as soon as there is a “non-TRUE”, as indicated by the above conceptual equivalence statement.

Also, since R version 3.5.0, `stopifnot(exprs = { ... })` can be used alternatively and may be preferable in the case of several expressions, as they are more conveniently evaluated interactively (“no extraneous , ”).

Since R version 3.4.0, when an expression (from `{ ... }`) is not true *and* is a call to `all.equal`, the error message will report the (first part of the) differences reported by `all.equal(*)`; since R 4.3.0, this happens for all calls where `"all.equal"` `pmatch()` es the function called, e.g., when that is called `all.equalShow`, see the example in `all.equal`.

Value

(`NULL` if all statements in `{ ... }` are `TRUE`.)

Note

Trying to use the `stopifnot(exprs = ...)` version via a shortcut, say,

```
assertWRONG <- function(exprs) stopifnot(exprs = exprs)
```

is delicate and the above is *not a good idea*. Contrary to `stopifnot()` which takes care to evaluate the parts of `exprs` one by one and stop at the first non-`TRUE`, the above short cut would typically evaluate all parts of `exprs` and pass the result, i.e., typically of the *last* entry of `exprs` to `stopifnot()`.

However, a more careful version,

```
assert <- function(exprs) eval.parent(substitute(stopifnot(exprs = exprs)))
```

may be a nice short cut for `stopifnot(exprs = *)` calls using the more commonly known verb as function name.

See Also

`stop`, `warning`; `assertCondition` in package **tools** complements `stopifnot()` for testing warnings and errors.

Examples

```
## NB: Some of these examples are expected to produce an error. To
##      prevent them from terminating a run with example() they are
##      piped into a call to try().

stopifnot(1 == 1, all.equal(pi, 3.14159265), 1 < 2) # all TRUE

m <- matrix(c(1,3,3,1), 2, 2)
stopifnot(m == t(m), diag(m) == rep(1, 2)) # all(.) |> TRUE

stopifnot(length(10)) |> try() # gives an error: '1' is *not* TRUE
## even when   if(1) "ok"   works

stopifnot(all.equal(pi, 3.141593), 2 < 2, (1:10 < 12), "a" < "b") |> try()
## More convenient for interactive "line by line" evaluation:
stopifnot(exprs = {
  all.equal(pi, 3.1415927)
  2 < 2
  1:10 < 12
  "a" < "b"
```

```

})) |> try()

eObj <- expression(2 < 3, 3 <= 3:6, 1:10 < 2)
stopifnot(exprObject = eObj) |> try()
stopifnot(exprObject = quote(3 == 3))
stopifnot(exprObject = TRUE)

# long all.equal() error messages are abbreviated:
stopifnot(all.equal(rep(list(pi),4), list(3.1, 3.14, 3.141, 3.1415))) |> try()

# The default error message can be overridden to be more informative:
m[1,2] <- 12
stopifnot("m must be symmetric"= m == t(m)) |> try()
#=> Error: m must be symmetric

##' warnifnot(): a "only-warning" version of stopifnot()
##' {Yes, learn how to use do.call(substitute, ...) in a powerful manner !!}
warnifnot <- stopifnot ; N <- length(bdy <- body(warnifnot))
bdy <- do.call(substitute, list(bdy, list(stopifnot = quote(warnifnot))))
bdy[[N-1]] <- do.call(substitute, list(bdy[[N-1]], list(stop = quote(warning))))
body(warnifnot) <- bdy
warnifnot(1 == 1, 1 < 2, 2 < 2) # => warns " 2 < 2 is not TRUE "
warnifnot(exprs = {
  1 == 1
  3 < 3 # => warns "3 < 3 is not TRUE"
})

```

strptime

Date-time Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```

## S3 method for class 'POSIXct'
format(x, format = "", tz = "", usetz = FALSE, ...)
## S3 method for class 'POSIXlt'
format(x, format = "", usetz = FALSE,
       digits = getOption("digits.secs"), ...)

## S3 method for class 'POSIXt'
as.character(x, digits = if(inherits(x, "POSIXlt")) 14L else 6L,
            OutDec = ".", ...)

strftime(x, format = "", tz = "", usetz = FALSE, ...)
strptime(x, format, tz = "")

```

Arguments

<code>x</code>	an object to be converted: a character vector for <code>strptime</code> , an object which can be converted to <code>"POSIXlt"</code> for <code>strftime</code> .
<code>tz</code>	a character string specifying the time zone to be used for the conversion. System-specific (see <code>as.POSIXlt</code>), but <code>"</code> is the current time zone, and <code>"GMT"</code> is UTC. Invalid values are most commonly treated as UTC, on some platforms with a warning.
<code>format</code>	a character string. The default for the <code>format</code> methods is <code>"%Y-%m-%d %H:%M:%S"</code> if any element has a time component which is not midnight, and <code>"%Y-%m-%d"</code> otherwise. In the first case and if <code>digits</code> is not <code>NULL</code> , i.e., by default when <code>options("digits.secs")</code> is set, up to the specified number of digits will be printed for seconds, using <code>"%OS<n>"</code> instead of <code>"%S"</code> in the format, see also ‘Details’.
<code>...</code>	further arguments to be passed from or to other methods; for <code>strftime()</code> , notably <code>digits</code> , passed to <code>format(<POSIXlt>)</code> .
<code>usetz</code>	logical. Should the time zone abbreviation be appended to the output? This is used in printing times, and more reliable than using <code>"%Z"</code> .
<code>digits</code>	integer determining the <code>format()</code> ing of seconds when needed. Note that the defaults for <code>format()</code> and <code>as.character()</code> differ on purpose, <code>as.character()</code> giving close to full accuracy as it does for numbers.
<code>OutDec</code>	a 1-character string specifying the decimal point to be used; the default is <i>not</i> <code>getOption("OutDec")</code> on purpose.

Details

The `format` and `as.character` methods and `strftime` convert objects from the classes `"POSIXlt"` and `"POSIXct"` to `character` vectors.

`strptime` converts character vectors to class `"POSIXlt"`: its input `x` is first converted by `as.character`. Each input string is processed as far as necessary for the format specified: any trailing characters are ignored.

`strftime` is a wrapper for `format.POSIXlt`, and it and `format.POSIXct` first convert to class `"POSIXlt"` by calling `as.POSIXlt` (so they also work for class `"Date"`). Note that only that conversion depends on the time zone. Since R version 4.2.0, `as.POSIXlt()` conversion now treats the non-finite numeric `-Inf`, `Inf`, `NA` and `NaN` differently (where previously all were treated as `NA`). Also the `format()` method for `POSIXlt` now treats these different non-finite times and dates analogously to type `double`.

The usual vector re-cycling rules are applied to `x` and `format` so the answer will be of length of the longer of these vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months, the AM/PM indicator (if used) and the separators in output formats such as `%x` and `%X`, via the setting of the `LC_TIME` locale category. The ‘current locale’ of the descriptions might mean the locale in use at the start of the R session or when these functions are first used. (For input, the locale-specific conversions can be changed by calling `Sys.setlocale` with category `LC_TIME` (or `LC_ALL`). For output, what happens depends on the OS but usually works.)

The details of the formats are platform-specific, but the following are likely to be widely available: most are defined by the POSIX standard. A *conversion specification* is introduced by `%`, usually followed by a single letter or `O` or `E` and then a single letter. Any character in the format string not part of a conversion specification is interpreted literally (and `%%` gives `%`). Widely implemented conversion specifications include

- `%a` Abbreviated weekday name in the current locale on this platform. (Also matches full name on input: in some locales there are no abbreviations of names.) Case-insensitive on input.
- `%A` Full weekday name in the current locale. (Also matches abbreviated name on input.) Case-insensitive on input.
- `%b` Abbreviated month name in the current locale on this platform. (Also matches full name on input: in some locales there are no abbreviations of names.) Case-insensitive on input.
- `%B` Full month name in the current locale. (Also matches abbreviated name on input.) Case-insensitive on input.
- `%c` Date and time. Locale-specific on output, "`%a %b %e %H:%M:%S %Y`" on input.
- `%C` Century (00–99): the integer part of the year divided by 100.
- `%d` Day of the month as decimal number (01–31).
- `%D` Date format such as `%m/%d/%y`: the C99 standard says it should be that exact format (but not all OSes comply).
- `%e` Day of the month as decimal number (1–31), with a leading space for a single-digit number.
- `%F` Equivalent to `%Y-%m-%d` (the ISO 8601 date format).
- `%g` The last two digits of the week-based year (see `%V`). (Accepted but ignored on input.)
- `%G` The week-based year (see `%V`) as a decimal number. (Accepted but ignored on input.)
- `%h` Equivalent to `%b`.
- `%H` Hours as decimal number (00–23). As a special exception strings such as `'24:00:00'` are accepted for input, since ISO 8601 allows these.
- `%I` Hours as decimal number (01–12). Ambiguous unless used in conjunction with `%p`.
- `%j` Day of year as decimal number (001–366): For input, 366 is only valid in a leap year.
- `%m` Month as decimal number (01–12).
- `%M` Minute as decimal number (00–59).
- `%n` Newline on output, arbitrary whitespace on input.
- `%p` AM/PM indicator in the locale. Used in conjunction with `%I` and **not** with `%H`. An empty string in some locales (for example on some OSes, non-English European locales including Russia). The behaviour is undefined if used for input in such a locale.
 For input the match is case-insensitive. Note that English locales do not necessarily use AM/PM: for example, `a.m./p.m.` has been encountered.
 Some platforms accept `%P` for output, which uses a lower-case version (`%p` may also use lower case): others will output `P`.
- `%r` For output, the 12-hour clock time (using the locale's AM or PM): only defined in some locales, and on some OSes misleading in locales which do not define an AM/PM indicator. For input, equivalent to `%I:%M:%S %p`.
- `%R` Equivalent to `%H:%M`.
- `%S` Second as integer (00–61), allowing for up to two leap-seconds (but POSIX-compliant implementations will ignore leap seconds).
- `%t` Tab on output, arbitrary whitespace on input.
- `%T` Equivalent to `%H:%M:%S`.
- `%u` Weekday as a decimal number (1–7, Monday is 1).
- `%U` Week of the year as decimal number (00–53) using Sunday as the first day 1 of the week (and typically with the first Sunday of the year as day 1 of week 1). The US convention.

- `%V` Week of the year as decimal number (01–53) as defined in ISO 8601. If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. See `%G (%g)` for the year corresponding to the week given by `%V`. (Accepted but ignored on input.)
- `%w` Weekday as decimal number (0–6, Sunday is 0).
- `%W` Week of the year as decimal number (00–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.
- `%x` Date. Locale-specific on output, "`%Y/%m/%d`" on input.
- `%X` Time. Locale-specific on output, "`%H:%M:%S`" on input.
- `%y` Year without century (00–99). On input, values 00 to 68 are prefixed by 20 and 69 to 99 by 19 – that is the behaviour specified by the 2018 POSIX standard, but it does also say ‘it is expected that in a future version the default century inferred from a 2-digit year will change’.
- `%Y` Year with century. Note that whereas there was no zero in the original Gregorian calendar, ISO 8601:2004 defines it to be valid (interpreted as 1BC): see [https://en.wikipedia.org/wiki/0_\(year\)](https://en.wikipedia.org/wiki/0_(year)). However, the standards also say that years before 1582 in its calendar should only be used with agreement of the parties involved.
For input, only years 0 : 9999 are accepted.
- `%z` Signed offset in hours and minutes from UTC, so `-0800` is 8 hours behind UTC. (Standard only for output. For input `R` currently supports it on all platforms – values from `-1400` to `+1400` are accepted.)
- `%Z` (Output only.) Time zone abbreviation as a character string (empty if not available). This may not be reliable when a time zone has changed abbreviations over the years.

Where leading zeros are shown they will be used on output but are optional on input. Names are matched case-insensitively on input: whether they are capitalized on output depends on the platform and the locale. Note that abbreviated names are platform-specific (although the standards specify that in the ‘C’ locale they must be the first three letters of the capitalized English name: this convention is widely used in English-language locales but for example the French month abbreviations are not the same on any two of Linux, macOS, Solaris and Windows). Knowing what the abbreviations are is essential if you wish to use `%a`, `%b` or `%h` as part of an input format: see the examples for how to check.

When `%z` or `%Z` is used for output with an object with an assigned time zone an attempt is made to use the values for that time zone — but it is not guaranteed to succeed.

The definition of ‘whitespace’ for `%n` and `%t` is platform-dependent: for most it does not include non-breaking spaces.

Not in the standards and less widely implemented are

- `%k` The 24-hour clock time with single digits preceded by a blank.
- `%l` The 12-hour clock time with single digits preceded by a blank.
- `%s` (Output only.) The number of seconds since the epoch.
- `%+` (Output only.) Similar to `%c`, often "`%a %b %e %H:%M:%S %Z %Y`". May depend on the locale.

For output there are also `%O[dHImMUVwWy]` which may emit numbers in an alternative locale-dependent format (e.g., roman numerals), and `%E[cCyYxX]` which can use an alternative ‘era’ (e.g., a different religious calendar). Which of these are supported is OS-dependent. These are accepted for input, but with the standard interpretation.

Specific to `R` is `%OSn`, which for output gives the seconds truncated to exactly $0 \leq n \leq 6$ decimal places. If `%OS` is not followed by a digit, it uses up to `digits` decimals (only as many as necessary, i.e., not producing extra trailing zeros. The default `digits = NULL` corresponds to `digits = 0`).

Note that the precedence is `format="..%OSn.." << digits=n`, the latter initialized by default from `getOption("digits.secs")`. Currently, for output (`strptime()` and `format(<POSIX.t>)`), only *one* "%OS" occurrence is handled (per format string).

Further, for `strptime %OS` will input seconds including fractional seconds (to full precision). Note that `%S` does not read or write fractional parts.

The behaviour of other conversion specifications (and even if other character sequences commencing with % *are* conversion specifications) is system-specific. Some systems document that the use of multi-byte characters in `format` is unsupported: UTF-8 locales are unlikely to cause a problem.

Value

The `format` methods and `strptime` return character vectors representing the time. NA times are returned as `NA_character_`.

`strptime` turns character representations into an object of class `"POSIXlt"`. The time zone is used to set the `isdst` component and to set the `"tzzone"` attribute if `tz != ""`. If the specified time is invalid (for example `"2010-02-30 08:00"`) all the components of the result are NA. (NB: this does means exactly what it says – if it is an invalid time, not just a time that does not exist in some time zone.)

Printing years

Everyone agrees that years from 1000 to 9999 should be printed with 4 digits, but the standards do not define what is to be done outside that range. For years 0 to 999 most OSes pad with zeros or spaces to 4 characters, but Linux/glibc outputs just the number.

OS facilities will probably not print years before 1 CE (aka 1 AD) ‘correctly’ (they tend to assume the existence of a year 0: see [https://en.wikipedia.org/wiki/0_\(year\)](https://en.wikipedia.org/wiki/0_(year)), and some OSes get them completely wrong). Common formats are `-45` and `-045`.

Years after 9999 and before -999 are normally printed with five or more characters.

Some platforms support modifiers from POSIX 2008 (and others). On Linux/glibc the format `"%04Y"` assures a minimum of four characters and zero-padding (the default is no padding). The internal code (as used on Windows and by default on macOS) uses zero-padding by default (this can be controlled by environment variable `R_PAD_YEARS_BY_ZERO`). On those platforms, formats `%04Y`, `%_4Y` and `%_Y` can be used for zero, space and no padding respectively. (On macOS, the native code (not the default) supports none of these and uses zero-padding to 4 digits.)

Time zone offsets

Offsets from GMT (also known as UTC) are part of the conversion between timezones and to/from class `"POSIXct"`, but cause difficulties as they are often computed incorrectly.

They conventionally have the opposite sign from time-zone specifications (see `Sys.timezone`): positive values are East of the meridian. Although there have been time zones with offsets like `+00:09:21` (Paris in 1900), and `-00:44:30` (Liberia until 1972), offsets are usually treated as whole numbers of minutes, and are most often seen in RFC 5322 email headers in forms like `-0800` (e.g., used on the Pacific coast of the USA in winter).

Format `%z` can be used for input or output: it is a character string, conventionally plus or minus followed by two digits for hours and two for minutes: the standards say that an empty string should be output if the offset is undetermined, but some systems use `+0000` or the offsets for the time zone in use for the current year. (On some platforms this works better after conversion to `"POSIXct"`. Some platforms only recognize hour or half-hour offsets for output.)

Using `%z` for input makes most sense with `tz = "UTC"`.

Sources

Input uses the POSIX function `strptime` and output the C99 function `strftime`.

However, not all OSes (notably Windows) provided `strptime` and many issues were found for those which did, so since 2000 R has used a fork of code from ‘glibc’. The forked code uses the system’s `strftime` to find the locale-specific day and month names and any AM/PM indicator.

On some platforms (including Windows and by default on macOS) the system’s `strftime` is replaced (along with most of the rest of the C-level datetime code) by code modified from IANA’s ‘tzcode’ distribution (<https://www.iana.org/time-zones>).

Note that as `strftime` is used for output (and not `wcsftime`), argument `format` is translated if necessary to the session encoding.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-28" and a time as "14:01:02" using leading zeroes as here. (The ISO form uses no space, possibly ‘T’, to separate dates and times: R uses a space by default.)

For `strptime` the input string need not specify the date completely: it is assumed that unspecified seconds, minutes or hours are zero, and an unspecified year, month or day is the current one. (However, if a month is specified, the day of that month has to be specified by `%d` or `%e` since the current day of the month need not be valid for the specified month.) Some components may be returned as NA (but an unknown `tzzone` component is represented by an empty string).

If the time zone specified is invalid on your system, what happens is system-specific but it will probably be ignored.

Remember that in most time zones some times do not occur and some occur twice because of transitions to/from ‘daylight saving’ (also known as ‘summer’) time. `strptime` does not validate such times (it does not assume a specific time zone), but conversion by `as.POSIXct` will do so. Conversion by `strftime` and formatting/printing uses OS facilities and may return nonsensical results for non-existent times at DST transitions.

In a C locale `%c` is required to be "%a %b %e %H:%M:%S %Y". As Windows does not comply (and uses a date format not understood outside N. America), that format is used by R on Windows in all locales.

There is a limit of 2048 bytes on each string produced by `strftime` and the `format` methods. As from R 4.3.0 attempting to exceed this is an error (previous versions silently truncated at 255 bytes).

Your system's help page on `strptime` to see how to specify their formats. (On some systems, including Windows, `strptime` is replaced by more comprehensive internal code.)

Examples

```
## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y %Z")

## time to sub-second accuracy (if supported by the OS)
format(Sys.time(), "%H:%M:%OS3")

## read in date info in format 'ddmmmyyyy'
## This will give NA(s) in some locales (especially non-English ones);
## setting the C locale as in the commented lines will overcome this on
## most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- strptime(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z
(chz <- as.character(z)) # same w/o TZ
## *here* (but not in general), the same as format():
stopifnot(exprs = {
  identical(chz, format(z))
  grepl("^1960-0[137]-[03][012]$", chz[!is.na(z)])
})

## read in date/time info in format 'm/d/y h:m:s'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
times <- c("23:03:20", "22:29:56", "01:03:30", "18:21:03", "16:56:26")
x <- paste(dates, times)
z2 <- strptime(x, "%m/%d/%y %H:%M:%S")
z2
## *here* (but not in general), the same as format():
stopifnot(identical(format(z2), as.character(z2)))

## time with fractional seconds (setting `tz = ..` for reproducible output)
z3 <- strptime("20/2/06 11:16:16.683", "%d/%m/%y %H:%M:%OS", tz = "UTC")
z3 # prints without fractional seconds by default, digits.sec = NULL ("= 0")
format(z3, digits = 3) # shows extra digits
format(z3, digits = 6) # still 3 digits: *not* showing trailing zeros
format(z3, format = "%Y-%m-%d %H:%M:%OS6") # *does* keep trailing zeros
```

```

op <- options(digits.secs = 3) # global option, the default for `digits`
z3 # shows the 3 extra digits
options(op)
as.character(z3) # ditto

## time zone names are not portable, but 'EST5EDT' comes pretty close.
## (but its interpretation may not be universal: see ?timezones)
z4 <- strptime(c("2006-01-08 10:07:52", "2006-08-07 19:33:02"),
               "%Y-%m-%d %H:%M:%S", tz = "EST5EDT")

z4
attr(z4, "tzone")
as.character(z4)
z4$sec[2] <- pi # "very" fractional seconds
as.character(z4) # shows full precision
format(z4) # no fractional sec
format(z4, digits=8) # shows only 6 (hard-wired maximum)
format(z4, digits=4)

## An RFC 5322 header (Eastern Canada, during DST)
## In a non-English locale the commented lines may be needed.

## prev <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
strptime("Tue, 23 Mar 2010 14:36:38 -0400", "%a, %d %b %Y %H:%M:%S %z")
## Sys.setlocale("LC_TIME", prev)

## Make sure you know what the abbreviated names are for you if you wish
## to use them for input (they are matched case-insensitively):
format(s1 <- seq.Date(as.Date('1978-01-01'), by = 'day', len = 7), "%a")
format(s2 <- seq.Date(as.Date('2000-01-01'), by = 'month', len = 12), "%b")

## Non-finite date-times :
format(as.POSIXct(Inf)) # "Inf" (was NA in R <= 4.1.x)
format(as.POSIXlt(c(-Inf, Inf, NaN, NA))) # were all NA

```

strrep

Repeat the Elements of a Character Vector

Description

Repeat the character strings in a character vector a given number of times (i.e., concatenate the respective numbers of copies of the strings).

Usage

```
strrep(x, times)
```

Arguments

<code>x</code>	a character vector, or an object which can be coerced to a character vector using <code>as.character</code> .
<code>times</code>	an integer vector giving the (non-negative) numbers of times to repeat the respective elements of <code>x</code> .

Details

The elements of `x` and `times` will be recycled as necessary (if one has no elements, and empty character vector is returned). Missing elements in `x` or `times` result in missing elements of the return value.

Value

A character vector with the elements of the given character vector repeated the given numbers of times.

Examples

```
strrep("ABC", 2)
strrep(c("A", "B", "C"), 1 : 3)
## Create vectors with the given numbers of spaces:
strrep(" ", 1 : 5)
```

strsplit

Split the Elements of a Character Vector

Description

Split the elements of a character vector `x` into substrings according to the matches to substring `split` within them.

Usage

```
strsplit(x, split, fixed = FALSE, perl = FALSE, useBytes = FALSE)
```

Arguments

<code>x</code>	character vector, each element of which is to be split. Other inputs, including a factor, will give an error.
<code>split</code>	character vector (or object which can be coerced to such) containing regular expression (s) (unless <code>fixed = TRUE</code>) to use for splitting. If empty matches occur, in particular if <code>split</code> has length 0, <code>x</code> is split into single characters. If <code>split</code> has length greater than 1, it is re-cycled along <code>x</code> .
<code>fixed</code>	logical. If <code>TRUE</code> match <code>split</code> exactly, otherwise use regular expressions. Has priority over <code>perl</code> .
<code>perl</code>	logical. Should Perl-compatible regexps be used?
<code>useBytes</code>	logical. If <code>TRUE</code> the matching is done byte-by-byte rather than character-by-character, and inputs with marked encodings are not converted. This is forced (with a warning) if any input is found which is marked as "bytes" (see Encoding).

Details

Argument `split` will be coerced to character, so you will see uses with `split = NULL` to mean `split = character(0)`, including in the examples below.

Note that splitting into single characters can be done *via* `split = character(0)` or `split = ""`; the two are equivalent. The definition of ‘character’ here depends on the locale: in a single-byte locale it is a byte, and in a multi-byte locale it is the unit represented by a ‘wide character’ (almost always a Unicode code point).

A missing value of `split` does not split the corresponding element(s) of `x` at all.

The algorithm applied to each input string is

```
repeat {
  if the string is empty
    break.
  if there is a match
    add the string to the left of the match to the output.
    remove the match and all to the left of it.
  else
    add the string to the output.
    break.
}
```

Note that this means that if there is a match at the beginning of a (non-empty) string, the first element of the output is "", but if there is a match at the end of the string, the output is the same as with the match removed.

Note also that if there is an empty match at the beginning of a non-empty string, the first character is returned and the algorithm continues with the rest of the string. This needs to be kept in mind when designing the regular expressions. For example, when looking for a word boundary followed by a letter ("`[[:<:]]`" with `perl = TRUE`), one can disallow a match at the beginning of a string (via "`(?!^)[[:<:]]`").

Invalid inputs in the current locale are warned about up to 5 times.

Value

A list of the same length as `x`, the *i*-th element of which contains the vector of splits of `x[i]`.

If any element of `x` or `split` is declared to be in UTF-8 (see [Encoding](#)), all non-ASCII character strings in the result will be in UTF-8 and have their encoding declared as UTF-8. (This also holds if any element is declared to be Latin-1 except in a Latin-1 locale.) For `perl = TRUE`, `useBytes = FALSE` all non-ASCII strings in a multibyte locale are translated to UTF-8.

If any element of `x` or `split` is marked as "bytes" (see [Encoding](#)), all non-ASCII character strings created by the splitting in the result will be marked as "bytes", but encoding of the resulting character strings not split is unspecified (may be "bytes" or the original). If no element of `x` or `split` is marked as "bytes", but `useBytes = TRUE`, even the encoding of the resulting character strings created by splitting is unspecified (may be "bytes" or "unknown", possibly invalid in the current encoding). Mixed use of "bytes" and other marked encodings is discouraged, but if still desired one may use `iconv` to re-encode the result e.g. to UTF-8 with suitably substituted invalid bytes.

Warning

An all too common mis-usage is to pass unnamed arguments which are then matched to one or more of `fixed`, `perl` and `useBytes`. So it is good practice to name all the arguments.

See Also

[paste](#) for the reverse, [grep](#) and [sub](#) for string search and manipulation; also [nchar](#), [substr](#), [startsWith](#), and [endsWith](#).

‘[regular expression](#)’ for the details of the pattern specification.

Option `PCRE_use_JIT` controls the details when `perl = TRUE`.

Examples

```
noquote(strsplit("A text I want to display with spaces", NULL)[[1]])

x <- c(as = "asfef", qu = "qwerty", "yuiop[, "b", "stuff.blah.yech")
# split x on the letter e
strsplit(x, "e")

unlist(strsplit("a.b.c", "."))
## [1] "" "" "" "" ""
## Note that 'split' is a regexp!
## If you really want to split on '.', use
unlist(strsplit("a.b.c", "[.]"))
## [1] "a" "b" "c"
## or
unlist(strsplit("a.b.c", ".", fixed = TRUE))

## a useful function: rev() for strings
strReverse <- function(x)
  sapply(lapply(strsplit(x, NULL), rev), paste, collapse = "")
strReverse(c("abc", "Statistics"))

## get the first names of the members of R-core
a <- readLines(file.path(R.home("doc"), "AUTHORS"))[-(1:8)]
a <- a[(0:2)-length(a)]
(a <- sub(".*", "", a))
# and reverse them
strReverse(a)

## Note that final empty strings are not produced:
strsplit(paste(c("", "a", ""), collapse="#"), split="#")[[1]]
# [1] "" "a"
## and also an empty string is only produced before a definite match:
strsplit("", " ")[[1]] # character(0)
strsplit(" ", " ")[[1]] # [1] ""
```

strtoi

Convert Strings to Integers

Description

Convert strings to integers according to the given base using the C function `strtol`, or choose a suitable base following the C rules.

Usage

```
strtoi(x, base = 0L)
```

Arguments

<code>x</code>	a character vector, or something coercible to this by as.character .
<code>base</code>	an integer which is between 2 and 36 inclusive, or zero (default).

Details

Conversion is based on the C library function `strtol`.

For the default `base = 0L`, the base chosen from the string representation of that element of `x`, so different elements can have different bases (see the first example). The standard C rules for choosing the base are that octal constants (prefix 0 not followed by `x` or `X`) and hexadecimal constants (prefix `0x` or `0X`) are interpreted as base 8 and 16; all other strings are interpreted as base 10.

For a base greater than 10, letters a to z (or A to Z) are used to represent 10 to 35.

Value

An integer vector of the same length as `x`. Values which cannot be interpreted as integers or would overflow are returned as [NA_integer_](#).

See Also

For decimal strings [as.integer](#) is equally useful.

Examples

```
strtoi(c("0xff", "077", "123"))
strtoi(c("ffff", "FFFF"), 16L)
strtoi(c("177", "377"), 8L)
```

strtrim

Trim Character Strings to Specified Display Widths

Description

Trim character strings to specified display widths.

Usage

```
strtrim(x, width)
```

Arguments

<code>x</code>	a character vector, or an object which can be coerced to a character vector by as.character .
<code>width</code>	positive integer values: recycled to the length of <code>x</code> .

Details

‘Width’ is interpreted as the display width in a monospaced font. What happens with non-printable characters (such as backspace, tab) is implementation-dependent and may depend on the locale (e.g., they may be included in the count or they may be omitted).

Using this function rather than [substr](#) is important when there might be double-width (e.g., Chinese/Japanese/Korean) characters in the character vector.

Value

A character vector of the same length and with the same attributes as `x` (after possible coercion).

Elements of the result will have the encoding declared as that of the current locale (see [Encoding](#)) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8.

Examples

```
strtrim(c("abcdef", "abcdef", "abcdef"), c(1,5,10))
```

structure	<i>Attribute Specification</i>
-----------	--------------------------------

Description

`structure` returns the given object with further [attributes](#) set.

Usage

```
structure(.Data, ...)
```

Arguments

<code>.Data</code>	an object which will have various attributes attached to it. From R 4.6.0, this must not be <code>NULL</code> (previously deprecated for years), nor any symbol or primitive function.
<code>...</code>	attributes, specified in <code>tag = value</code> form, which will be attached to data.

Details

Adding a class `"factor"` will ensure that numeric codes are given integer storage mode.

For historical reasons (these names are used when deparsing), attributes `".Dim"`, `".Dimnames"`, `".Names"`, `".Tsp"` and `".Label"` are renamed to `"dim"`, `"dimnames"`, `"names"`, `"tsp"` and `"levels"`.

It is possible to give the same tag more than once, in which case the last value assigned wins. As with other ways of assigning attributes, using `tag = NULL` removes attribute `tag` from `.Data` if it is present.

[attributes](#), [attr](#).

Examples

```
structure(1:6, dim = 2:3)
```

strwrap

*Wrap Character Strings to Format Paragraphs***Description**

Each character string in the input is first split into paragraphs (or lines containing whitespace only). The paragraphs are then formatted by breaking lines at word boundaries. The target columns for wrapping lines and the indentation of the first and all subsequent lines of a paragraph can be controlled independently.

Usage

```
strwrap(x, width = 0.9 * getOption("width"), indent = 0,
        exdent = 0, prefix = "", simplify = TRUE, initial = prefix)
```

Arguments

<code>x</code>	a character vector, or an object which can be converted to a character vector by <code>as.character</code> .
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.
<code>indent</code>	a non-negative integer giving the indentation of the first line in a paragraph.
<code>exdent</code>	a non-negative integer specifying the indentation of subsequent lines in paragraphs.
<code>prefix, initial</code>	a character string to be used as prefix for each line except the first, for which <code>initial</code> is used.
<code>simplify</code>	a logical. If <code>TRUE</code> , the result is a single character vector of line text; otherwise, it is a list of the same length as <code>x</code> the elements of which are character vectors of line text obtained from the corresponding element of <code>x</code> . (Hence, the result in the former case is obtained by unlisting that of the latter.)

Details

Whitespace (space, tab or newline characters) in the input is destroyed. Double spaces after periods, question and explanation marks (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

Value

A character vector (if `simplify` is `TRUE`), or a list of such character vectors, with declared input encodings preserved.

Examples

```
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n[ \t\n]*\n"))[-(1:3)]
## Join the rest
```

```

x <- paste(x, collapse = "\n\n")
## Now for some fun:
writeLines(strwrap(x, width = 60))
writeLines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, replace = TRUE),
  function(x) substring("aaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40,
  function(m)
    c(target = m, actual = max(nchar(strwrap(x, m)))))

```

subset

*Subsetting Vectors, Matrices and Data Frames***Description**

Return subsets of vectors, matrices or data frames which meet conditions.

Usage

```

subset(x, ...)

## Default S3 method:
subset(x, subset, ...)

## S3 method for class 'matrix'
subset(x, subset, select, drop = FALSE, ...)

## S3 method for class 'data.frame'
subset(x, subset, select, drop = FALSE, ...)

```

Arguments

x	object to be subsetting.
subset	logical expression indicating elements or rows to keep: missing values are taken as false.
select	expression, indicating columns to select from a data frame.
drop	passed on to [indexing operator.
...	further arguments to be passed to or from other methods.

Details

This is a generic function, with methods supplied for matrices, data frames and vectors (including lists). Packages and users can add further methods.

For ordinary vectors, the result is simply `x[subset & !is.na(subset)]`.

For data frames, the `subset` argument works on the rows. Note that `subset` will be evaluated in the data frame, so columns can be referred to (by name) as variables in the expression (see the examples).

The `select` argument exists only for the methods for data frames and matrices. It works by first replacing column names in the selection expression with the corresponding column numbers in the data frame and then using the resulting integer vector to index the columns. This allows the use of the standard indexing conventions so that for example ranges of columns can be specified easily, or single columns can be dropped (see the examples).

The `drop` argument is passed on to the indexing method for matrices and data frames: note that the default for matrices is different from that for indexing.

Factors may have empty levels after subsetting; unused levels are not automatically removed. See [droplevels](#) for a way to drop all unused levels from a data frame.

Value

An object similar to `x` contain just the selected elements (for a vector), rows and columns (for a matrix or data frame), and so on.

Warning

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting functions like `[`, and in particular the non-standard evaluation of argument `subset` can have unanticipated consequences.

Examples

```
subset(airquality, Temp > 80, select = c(Ozone, Temp))
subset(airquality, Day == 1, select = -Temp)
subset(airquality, select = Ozone:Wind)

with(airquality, subset(Ozone, Temp > 80))

## sometimes requiring a logical 'subset' argument is a nuisance
nm <- rownames(state.x77)
start_with_M <- nm %in% grep("^M", nm, value = TRUE)
subset(state.x77, start_with_M, Illiteracy:Murder)
# but in recent versions of R this can simply be
subset(state.x77, grepl("^M", nm), Illiteracy:Murder)
```

Description

`substitute` returns the parse tree for the (unevaluated) expression `expr`, substituting any variables bound in `env`.

`quote` simply returns its argument. The argument is not evaluated and can be any R expression.

`enquote` is a simple one-line utility which transforms a call of the form `Foo(...)` into the call `quote(Foo(...))`. This is typically used to protect a `call` from early evaluation.

Usage

```
substitute(expr, env)
quote(expr)
enquote(cl)
```

Arguments

<code>expr</code>	any syntactically valid R expression.
<code>cl</code>	a <code>call</code> , i.e., an R object of <code>class</code> (and <code>mode</code>) <code>"call"</code> .
<code>env</code>	an environment or a list object. Defaults to the current evaluation environment.

Details

The typical use of `substitute` is to create informative labels for data sets and plots. The `myplot` example below shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

Substitution takes place by examining each component of the parse tree as follows: If it is not a bound symbol in `env`, it is unchanged. If it is a promise object, i.e., a formal argument to a function or explicitly created using `delayedAssign()`, the expression slot of the promise replaces the symbol. If it is an ordinary variable, its value is substituted, unless `env` is `.GlobalEnv` in which case the symbol is left unchanged.

Both `quote` and `substitute` are ‘special’ `primitive` functions which do not evaluate their arguments.

Value

The `mode` of the result is generally `"call"` but may in principle be any type. In particular, single-variable expressions have `mode` `"name"` and constants have the appropriate base mode.

Note

`substitute` works on a purely lexical basis. There is no guarantee that the resulting expression makes any sense.

Substituting and quoting often cause confusion when the argument is `expression(...)`. The result is a call to the `expression` constructor function and needs to be evaluated with `eval` to give the actual expression object.

[all.names](#) to retrieve the symbol names from an expression or call.

Examples

```
require(graphics)
(s.e <- substitute(expression(a + b), list(a = 1))) #> expression(1 + b)
(s.s <- substitute( a + b, list(a = 1))) #> 1 + b
c(mode(s.e), typeof(s.e)) # "call", "language"
c(mode(s.s), typeof(s.s)) # (the same)
# but:
(e.s.e <- eval(s.e)) #> expression(1 + b)
c(mode(e.s.e), typeof(e.s.e)) # "expression", "expression"

substitute(x <- x + 1, list(x = 1)) # nonsense

myplot <- function(x, y)
  plot(x, y, xlab = deparse1(substitute(x)),
       ylab = deparse1(substitute(y)))

## Simple examples about lazy evaluation, etc:

f1 <- function(x, y = x) { x <- x + 1; y }
s1 <- function(x, y = substitute(x)) { x <- x + 1; y }
s2 <- function(x, y) { if(missing(y)) y <- substitute(x); x <- x + 1; y }
a <- 10
f1(a) # 11
s1(a) # 11
s2(a) # a
typeof(s2(a)) # "symbol"
```

substr

Substrings of a Character Vector

Description

Extract or replace substrings in a character vector.

Usage

```
substr(x, start, stop)
substring(text, first, last = NULL)

substr(x, start, stop) <- value
substring(text, first, last = NULL) <- value
```

Arguments

<code>x, text</code>	a character vector.
<code>start, first</code>	integer. The first character to be extracted or replaced.
<code>stop, last</code>	integer or NULL. The last character to be extracted or replaced.
<code>value</code>	a character vector, recycled if necessary.

Details

`substring` is compatible with `S`, with `first` and `last` instead of `start` and `stop`. For vector arguments, it expands the arguments cyclically to the length of the longest *provided* none are of zero length.

When extracting, if `start` is larger than the string length then "" is returned. If `stop` is larger than the string length then the portion until the end of the string is returned.

If `stop` is NULL, `substr` will return substrings of `x` from `start` to the end of each string in `x`.

For the extraction functions, `x` or `text` will be converted to a character vector by [as.character](#) if it is not already one.

For the replacement functions, if `start` is larger than the string length then no replacement is done. If the portion to be replaced is longer than the replacement string, then only the portion the length of the string is replaced.

If any argument has an NA element, the corresponding element of the answer is NA.

Elements of the result will have the encoding declared as that of the current locale (see [Encoding](#)) if the corresponding input had a declared Latin-1 or UTF-8 encoding and the current locale is either Latin-1 or UTF-8.

If an input element has declared "bytes" encoding (see [Encoding](#)), the subsetting is done in units of bytes not characters.

Value

For `substr`, a character vector of the same length and with the same attributes as `x` (after possible coercion). `start` and `stop` are recycled as necessary.

For `substring`, a character vector of length the longest of the arguments. This will have names taken from `x` (if it has any after coercion, repeated as needed), and other attributes copied from `x` if it is the longest of the arguments).

For the replacement functions, a character vector of the same length as `x` or `text`, with [attributes](#) such as [names](#) preserved.

Elements of `x` or `text` with a declared encoding (see [Encoding](#)) will be returned with the same encoding.

Note

The `S` version of `substring<-` ignores `last`; this version does not.

These functions are often used with [nchar](#) to truncate a display. That does not really work (you want to limit the width, not the number of characters, so it would be better to use [strtrim](#)), but at least make sure you use the default `nchar(type = "chars")`.

stopifnot(x == X, identical(aX, attributes(X)), nzchar(comment(X)))
```

sum

Sum of Vector Elements

Description

`sum` returns the sum of all the values present in its arguments.

Usage

```
sum(..., na.rm = FALSE)
```

Arguments

`...` numeric or complex or logical vectors.

`na.rm` logical (TRUE or FALSE). Should missing values (including NaN) be removed?

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

If `na.rm` is FALSE an NA or NaN value in any of the arguments will cause a value of NA or NaN to be returned, otherwise NA and NaN values are ignored.

Logical true values are regarded as one, false values as zero. For historical reasons, NULL is accepted and treated as if it were `integer(0)`.

Loss of accuracy can occur when summing values of different signs: this can even occur for sufficiently long integer inputs if the partial sums would cause integer overflow. Where possible extended-precision accumulators are used, typically well supported with C99 and newer, but possibly platform-dependent.

Value

The sum. If all of the ... arguments are of type integer or logical, then the sum is `integer` when possible and is `double` otherwise. Integer overflow should no longer happen since R version 3.5.0. For other argument types it is a length-one numeric (`double`) or complex vector.

NB: the sum of an empty set is zero, by definition.

S4 methods

This is part of the S4 `Summary` group generic. Methods for it must use the signature `x, ..., na.rm`.

`'plotmath'` for the use of `sum` in plot annotation.

See Also

`colSums` for row and column sums.

Examples

```
## Pass a vector to sum, and it will add the elements together.
sum(1:5)

## Pass several numbers to sum, and it also adds the elements.
sum(1, 2, 3, 4, 5)

## In fact, you can pass vectors into several arguments, and everything gets added.
sum(1:2, 3:5)

## If there are missing values, the sum is unknown, i.e., also missing, ....
sum(1:5, NA)
## ... unless we exclude missing values explicitly:
sum(1:5, NA, na.rm = TRUE)
```

Description

`summary` is a generic function used to produce result summaries of the results of various model fitting functions. The function invokes particular `methods` which depend on the `class` of the first argument.

Usage

```
summary(object, ...)

## Default S3 method:
summary(object, ..., digits, quantile.type = 7,
        character.method = c("default", "factor"),
        polar = TRUE)

## S3 method for class 'data.frame'
summary(object, maxsum = 7,
        digits = max(3, getOption("digits")-3), ...)

## S3 method for class 'factor'
summary(object, maxsum = 100, ...)

## S3 method for class 'matrix'
summary(object, ...)

## S3 method for class 'summaryDefault'
format(x, digits = max(3L, getOption("digits") - 3L), zdigits = 4L, ...)
## S3 method for class 'summaryDefault'
print(x, digits = max(3L, getOption("digits") - 3L), zdigits = 4L, ...)
```

Arguments

<code>object</code>	an object for which a summary is desired.
<code>x</code>	a result of the <i>default</i> method of <code>summary()</code> .
<code>maxsum</code>	integer, indicating how many levels should be shown for factors .
<code>digits</code>	integer (or <code>NULL</code> , see ‘Details’), used for number formatting with <code>signif()</code> (for <code>summary.default</code>) or <code>format()</code> (for <code>summary.data.frame</code>). In <code>summary.default</code> , if not specified (i.e., <code>missing()</code>), <code>signif()</code> will <i>not</i> be called anymore (since R ≥ 3.4.0, where the default has been changed to only round in the <code>print</code> and <code>format</code> methods).
<code>zdigits</code>	integer, typically positive to be used in the internal <code>zapsmall(*, digits = digits + zdigits)</code> call.
<code>quantile.type</code>	integer code used in <code>quantile(*, type=quantile.type)</code> for the default method.
<code>character.method</code>	a character string, indicating how character vectors are summarized: the "default" method counts unique and blank (whitespace-only, i.e., empty after <code>trimws</code>) elements and computes the <code>nchar</code> range. Choose "factor" to summarize <code>factor(object)</code> , resorting to the factor method. Set to <code>NULL</code> to fall back to the generic summary as in R < 4.6.0.
<code>polar</code>	logical, indicating if polar coordinates (modulus and argument) of complex numbers should be summarized rather than Cartesian ones (real and imaginary parts).
<code>...</code>	additional arguments affecting the summary produced.

Details

For `factor`s, the frequency of the first `maxsum - 1` most frequent levels is shown, and the less frequent levels are summarized in "(Other)" (resulting in at most `maxsum` frequencies).

The `digits` argument may be `NULL` for some methods specifying to use the default value, e.g., for the `"summaryDefault"` `format()` method.

The functions `summary.lm` and `summary.glm` are examples of particular methods which summarize the results produced by `lm` and `glm`.

Value

The form of the value returned by `summary` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

The default method returns an object of class `c("summaryDefault", "table")` which has specialized `format` and `print` methods. The `factor` method returns an integer vector.

The matrix and data frame methods return a matrix of class `"table"`, obtained by applying `summary` to each column and collating the results.

(szp <- summary(z))      # using Mod(.) and Arg(.)
(szc <- summary(z, polar = FALSE)) # Re(.) and Im(.)

summary(rx <- as.raw(1.5*x)) # default: only {length(), class(), mode()}

```

svd

*Singular Value Decomposition of a Matrix***Description**

Compute the singular-value decomposition of a rectangular matrix.

Usage

```

svd(x, nu = min(n, p), nv = min(n, p), LINPACK = FALSE)

La.svd(x, nu = min(n, p), nv = min(n, p))

```

Arguments

<code>x</code>	a numeric or complex matrix whose SVD decomposition is to be computed. Logical matrices are coerced to numeric.
<code>nu</code>	the number of left singular vectors to be computed. This must be between 0 and <code>n = nrow(x)</code> .
<code>nv</code>	the number of right singular vectors to be computed. This must be between 0 and <code>p = ncol(x)</code> .
<code>LINPACK</code>	logical. Defunct and an error.

Details

The singular value decomposition plays an important role in many statistical techniques. `svd` and `La.svd` provide two interfaces which differ in their return values.

Computing the singular vectors is the slow part for large matrices. The computation will be more efficient if both `nu <= min(n, p)` and `nv <= min(n, p)`, and even more so if both are zero.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code (most often 1): these can only be interpreted by detailed study of the FORTRAN code but mean that the algorithm failed to converge.

Missing, NaN or infinite values in `x` will given an error.

Value

The SVD decomposition of the matrix as computed by LAPACK,

$$X = UDV',$$

where U and V are orthogonal, V' means V *transposed* (and conjugated for complex input), and D is a diagonal matrix with the (non-negative) singular values D_{ii} in decreasing order. Equivalently, $D = U'XV$, which is verified in the examples.

The returned value is a list with components

<code>d</code>	a vector containing the singular values of <code>x</code> , of length <code>min(n, p)</code> , sorted decreasingly.
<code>u</code>	a matrix whose columns contain the left singular vectors of <code>x</code> , present if <code>nu > 0</code> . Dimension <code>c(n, nu)</code> .
<code>v</code>	a matrix whose columns contain the right singular vectors of <code>x</code> , present if <code>nv > 0</code> . Dimension <code>c(p, nv)</code> .

Recall that the singular vectors are only defined up to sign (a constant of modulus one in the complex case). If a left singular vector has its sign changed, changing the sign of the corresponding right vector gives an equivalent decomposition.

For `La.svd` the return value replaces `v` by `vt`, the (conjugated if complex) transpose of `v`.

Source

The main functions used are the LAPACK routines `DGESDD` and `ZGESDD`.

LAPACK is from <https://netlib.org/lapack/> and its guide is listed in the references.

s$u %*% D %*% t(s$v) # X = U D V'
t(s$u) %*% X %*% s$v # D = U' X V
```

sweep

Sweep out Array Summaries

Description

Return an array obtained from an input array by sweeping out a summary statistic.

Usage

```
sweep(x, MARGIN, STATS, FUN = "-", check.margin = TRUE, ...)
```

Arguments

<code>x</code>	an array, including a matrix.
<code>MARGIN</code>	a vector of indices giving the extent(s) of <code>x</code> which correspond to <code>STATS</code> . Where <code>x</code> has named <code>dimnames</code> , it can be a character vector selecting dimension names.
<code>STATS</code>	the summary statistic which is to be swept out.
<code>FUN</code>	the function to be used to carry out the sweep.
<code>check.margin</code>	logical. If <code>TRUE</code> (the default), warn if the length or dimensions of <code>STATS</code> do not match the specified dimensions of <code>x</code> . Set to <code>FALSE</code> for a small speed gain when you <i>know</i> that dimensions match.
<code>...</code>	optional arguments to <code>FUN</code> .

Details

`FUN` is found by a call to `match.fun`. As in the default, binary operators can be supplied if quoted or backquoted.

`FUN` should be a function of two arguments: it will be called with arguments `x` and an array of the same dimensions generated from `STATS` by `aperm`.

The consistency check among `STATS`, `MARGIN` and `x` is stricter if `STATS` is an array than if it is a vector. In the vector case, some kinds of recycling are allowed without a warning. Use `sweep(x, MARGIN, as.array(STATS))` if `STATS` is a vector and you want to be warned if any recycling occurs.

Value

An array with the same shape as `x`, but with the summary statistics swept out.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`apply` on which `sweep` used to be based; `scale` for centering and scaling.

Examples

```
require(stats) # for median
med.att <- apply(attitude, 2, median)
sweep(data.matrix(attitude), 2, med.att) # subtract the column medians

## More sweeping:
A <- array(1:24, dim = 4:2)

## no warnings in normal use
sweep(A, 1, 5)
(A.min <- apply(A, 1, min)) # == 1:4
sweep(A, 1, A.min)
sweep(A, 1:2, apply(A, 1:2, median))

## warnings when mismatch
sweep(A, 1, 1:3) # STATS does not recycle
sweep(A, 1, 6:1) # STATS is longer

## exact recycling:
sweep(A, 1, 1:2) # no warning
sweep(A, 1, as.array(1:2)) # warning

## Using named dimnames

dimnames(A) <- list(fee=1:4, fie=1:3, fum=1:2)

mn_fum_fie <- apply(A, c("fum", "fie"), mean)
mn_fum_fie
sweep(A, c("fum", "fie"), mn_fum_fie)
```

switch

Select One of a List of Alternatives

Description

`switch` evaluates `EXPR` and accordingly chooses one of the further arguments (in ...).

Usage

```
switch(EXPR, ...)
```

Arguments

<code>EXPR</code>	an expression evaluating to a number or a character string.
...	the list of alternatives. If it is intended that <code>EXPR</code> has a character-string value these will be named, perhaps except for one alternative to be used as a ‘default’ value.

Details

`switch` works in two distinct ways depending whether the first argument evaluates to a character string or a number.

If the value of `EXPR` is not a character string it is coerced to integer. Note that this also happens for [factors](#), with a warning, as typically the character level is meant. If the integer is between 1 and `nargs() - 1` then the corresponding element of `...` is evaluated and the result returned: thus if the first argument is 3 then the fourth argument is evaluated and returned.

If `EXPR` evaluates to a character string then that string is matched (exactly) to the names of the elements in `...`. If there is a match then that element is evaluated unless it is missing, in which case the next non-missing element is evaluated, so for example `switch("cc", a = 1, cc =, cd =, d = 2)` evaluates to 2. If there is more than one match, the first matching element is used. In the case of no match, if there is an unnamed element of `...` its value is returned. (If there is more than one such argument an error is signaled.)

The first argument is always taken to be `EXPR`: if it is named its name must (partially) match.

A warning is signaled if no alternatives are provided, as this is usually a coding error.

This is implemented as a [primitive](#) function that only evaluates its first argument and one other if one is selected.

Value

The value of one of the elements of `...`, or `NULL`, invisibly (whenever no element is selected).

The result has the visibility (see [invisible](#)) of the element evaluated.

Warning

It is possible to write calls to `switch` that can be confusing and may not work in the same way in earlier versions of R. For compatibility (and clarity), always have `EXPR` as the first argument, naming it if partial matching is a possibility. For the character-string form, have a single unnamed argument as the default after the named values.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

Examples

```
require(stats)
centre <- function(x, type) {
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
centre(x, "mean")
centre(x, "median")
centre(x, "trimmed")

ccc <- c("b", "QQ", "a", "A", "bb")
# note: cat() produces no output for NULL
for(ch in ccc)
  cat(ch, ":", switch(EXPR = ch, a = 1, b = 2:3), "\n")
for(ch in ccc)
  cat(ch, ":", switch(EXPR = ch, a =, A = 1, b = 2:3, "Otherwise: last"), "\n")
```

```
## switch(f, *) with a factor f
ff <- gl(3,1, labels=LETTERS[3:1])
ff[1] # C
## so one might expect " is C" here, but
switch(ff[1], A = "I am A", B="Bb..", C=" is C")# -> "I am A"
## so we give a warning

## Numeric EXPR does not allow a default value to be specified
## -- it is always NULL
for(i in c(-1:3, 9)) print(switch(i, 1, 2 , 3, 4))

## visibility
switch(1, invisible(pi), pi)
switch(2, invisible(pi), pi)
```

Syntax

Operator Syntax and Precedence

Description

Outlines R syntax and gives the precedence of operators.

Details

The following unary and binary operators are defined. They are listed in precedence groups, from highest to lowest.

:: :::	access variables in a namespace
\$ @	component / slot extraction
[[[	indexing
^	exponentiation (right to left)
- +	unary minus and plus
:	sequence operator
%any% >	special operators (including %% and %/%)
* /	multiply, divide
+ -	(binary) add, subtract
< > <= >= == !=	ordering and comparison
!	negation
& &&	and
	or
~	as in formulae
-> ->>	rightwards assignment
<- <<-	assignment (right to left)
=	assignment (right to left)
?	help (unary and binary)

Within an expression operators of equal precedence are evaluated from left to right except where indicated. (Note that = is not necessarily an operator.)

The binary operators ::, :::, \$ and @ require names or string constants on the right hand side, and the first two also require them on the left.

The links in the **See Also** section cover most other aspects of the basic syntax.

Note

There are substantial precedence differences between R and S. In particular, in S ? has the same precedence as (binary) + – and & && | | | have equal precedence.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[Arithmetic](#), [Comparison](#), [Control](#), [Extract](#), [Logic](#), [NumericConstants](#), [Paren](#), [Quotes](#), [Reserved](#).

Section “[Expressions](#)” in *The R Language Definition*.

Examples

```
## Logical AND ("&&") has higher precedence than OR ("||"):
TRUE || TRUE && FALSE # is the same as
TRUE || (TRUE && FALSE) # and different from
(TRUE || TRUE) && FALSE

## Special operators have higher precedence than "!" (logical NOT).
## You can use this for %in% :
! 1:10 %in% c(2, 3, 5, 7) # same as !(1:10 %in% c(2, 3, 5, 7))
## but we strongly advise to use the "!( ... )" form in this case!

## '=' has lower precedence than '<-' ... so you should not mix them
## (and '<-' is considered better style anyway):
## Not run: ## Consequently, this gives a ("non-catchable") error
x <- y = 5 #-> Error in (x <- y) = 5 : ....

## End(Not run)
```

Sys.getenv

Get Environment Variables

Description

`Sys.getenv` obtains the values of the environment variables.

Usage

```
Sys.getenv(x = NULL, unset = "", names = NA)
```

Arguments

<code>x</code>	a character vector, or <code>NULL</code> .
<code>unset</code>	a character string.
<code>names</code>	logical: should the result be named? If <code>NA</code> (the default) single-element results are not named whereas multi-element results are.

Details

Both arguments will be coerced to character if necessary.

Setting `unset = NA` will enable unset variables and those set to the value `" "` to be distinguished, *if the OS does*. POSIX requires the OS to distinguish, and all known current R platforms do.

Value

A vector of the same length as `x`, with (if `names == TRUE`) the variable names as its `names` attribute. Each element holds the value of the environment variable named by the corresponding component of `x` (or the value of `unset` if no environment variable with that name was found).

On most platforms `Sys.getenv()` will return a named vector giving the values of all the environment variables, sorted in the current locale. It may be confused by names containing `=` which some platforms allow but POSIX does not. (Windows is such a platform: there names including `=` are truncated just before the first `=`.)

When `x` is missing and `names` is not false, the result is of class `"Dlist"` in order to get a nice `print` method.

See Also

`Sys.setenv`, `Sys.getlocale` for the locale in use, `getwd` for the working directory.

The help for `'environment variables'` lists many of the environment variables used by R.

Examples

```
## whether HOST is set will be shell-dependent e.g. Solaris' csh did not.
Sys.getenv(c("R_HOME", "R_PAPERSIZE", "R_PRINTCMD", "HOST"))

s <- Sys.getenv() # *all* environment variables
op <- options(width=111) # (nice printing)
names(s)          # all settings (the values could be very long)
head(s, 12)       # using the Dlist print() method

## Language and Locale settings -- but rather use Sys.getlocale()
s[grepl("^L(C|ANG)", names(s))]
## typically R-related:
s[grepl("^_?R_", names(s))]
options(op) # reset
```

Sys.getpid

Get the Process ID of the R Session

Description

Get the process ID of the R Session. It is guaranteed by the operating system that two R sessions running simultaneously will have different IDs, but it is possible that R sessions running at different times will have the same ID.

Usage

```
Sys.getpid()
```

Value

An integer, often between 1 and 32767 under Unix-alikes (but for example FreeBSD and macOS use IDs up to 99999) and a positive integer (up to 32767) under Windows.

Examples

```
Sys.getpid()

## Show files opened from this R process
if(.Platform$OS.type == "unix") ## on Unix-alikes such Linux, macOS, FreeBSD:
  system(paste("lsof -p", Sys.getpid()))
```

Sys.glob

Wildcard Expansion on File Paths

Description

Function to do wildcard expansion (also known as ‘globbing’) on file paths.

Usage

```
Sys.glob(paths, dirmark = FALSE)
```

Arguments

paths	character vector of patterns for relative or absolute filepaths. Missing values will be ignored.
dirmark	logical: should matches to directories from patterns that do not already end in / have a slash appended? May not be supported on all platforms.

Details

This expands tilde (see [tilde expansion](#)) and wildcards in file paths. For precise details of wildcards expansion, see your system’s documentation on the glob system call. There is a POSIX 1003.2 standard (see <https://pubs.opengroup.org/onlinepubs/9699919799/functions/glob.html>) but some OSes will go beyond this.

All systems should interpret * (match zero or more characters), ? (match a single character) and (probably) [(begin a character class or range). The handling of paths ending with a separator is system-dependent. On a POSIX-2008 compliant OS they will match directories (only), but as they are not valid filepaths on Windows, they match nothing there. (Earlier POSIX standards allowed them to match files.)

The rest of these details are indicative (and based on the POSIX standard).

If a filename starts with . this may need to be matched explicitly: for example Sys.glob("*.RData") may or may not match ‘.RData’ but will not usually match ‘.aa.RData’. Note that this is platform-dependent: e.g. on Solaris Sys.glob("*.") matches ‘.’ and ‘..’.

[begins a character class. If the first character in [...] is not !, this is a character class which matches a single character against any of the characters specified. The class cannot be empty, so] can be included provided it is first. If the first character is !, the character class matches a single

character which is *none* of the specified characters. Whether `.` in a character class matches a leading `.` in the filename is OS-dependent.

Character classes can include ranges such as `[A-Z]`: include `-` as a character by having it first or last in a class. (The interpretation of ranges should be locale-specific, so the example is not a good idea in an Estonian locale.)

One can remove the special meaning of `?`, `*` and `[` by preceding them by a backslash (except within a character class).

Value

A character vector of matched file paths. The order is system-specific (but in the order of the elements of `paths`): it is normally collated in either the current locale or in byte (ASCII) order; however, on Windows collation is in the order of Unicode points.

Directory errors are normally ignored, so the matches are to accessible file paths (but not necessarily accessible files).

See Also

[path.expand](#).

[Quotes](#) for handling backslashes in character strings.

Examples

```
Sys.glob(file.path(R.home(), "library", "*", "R", "*.rdx"))
```

Sys.info

Extract System and User Information

Description

Reports system and user information.

Usage

```
Sys.info()
```

Details

This uses POSIX or Windows system calls. Note that OS names (`sysname`) might not be what you expect: for example macOS identifies itself as ‘Darwin’ and Solaris as ‘SunOS’.

`Sys.info()` returns details of the platform R is running on, whereas [R.version](#) gives details of the platform R was built on: the `release` and `version` may well be different.

Value

A character vector with fields

<code>sysname</code>	The operating system name.
<code>release</code>	The OS release.
<code>version</code>	The OS version.
<code>nodename</code>	A name by which the machine is known on the network (if any).
<code>machine</code>	A concise description of the hardware, often the CPU type.
<code>login</code>	The user's login name, or "unknown" if it cannot be ascertained.
<code>user</code>	The name of the real user ID, or "unknown" if it cannot be ascertained.
<code>effective_user</code>	The name of the effective user ID, or "unknown" if it cannot be ascertained. This may differ from the real user in 'set-user-ID' processes.
<code>udomain</code>	The domain name for the user. Only available on Windows.

On Unix-alike platforms: The first five fields come from the `uname(2)` system call. The login name comes from `getlogin(2)`, and the user names from `getpwuid(getuid())` and `getpuid(geteuid())`.

On Windows: Fields `login`, `user` and `effective_user` give the same value. `udomain` is the corresponding domain.

Note

The meaning of `release` and `version` is system-dependent: on a Unix-alike they normally refer to the kernel. There, usually `release` contains a numeric version and `version` gives additional information. Examples for `release`:

```
"4.17.11-200.fc28.x86_64" # Linux (Fedora)
"3.16.0-5-amd64"         # Linux (Debian)
"17.7.0"                 # macOS 10.13.6
"5.11"                   # Solaris
```

There is no guarantee that the node or login or user names will be what you might reasonably expect. (In particular on some Linux distributions the login name is unknown from sessions with re-directed inputs.)

The use of alternatives such as `system("whoami")` is not portable: the POSIX command `system("id")` is much more portable on Unix-alikes, provided only the POSIX options `'-[Ggu][nr]'` are used (and not the many BSD and GNU extensions). `whoami` is equivalent to `id -un` (on Solaris, `/usr/xpg4/bin/id -un`).

Windows may report unexpected versions: see the help for `win.version`.

See Also

`.Platform`, and `R.version.sessionInfo()` gives a synopsis of both your system and the R session (and gives the OS version in a human-readable form).

Examples

```
Sys.info()
## An alternative (and probably better) way to get the login name on Unix
Sys.getenv("LOGNAME")
```

Sys.localeconv	<i>Find Details of the Numerical and Monetary Representations in the Current Locale</i>
----------------	---

Description

Get details of the numerical and monetary representations in the current locale.

Usage

```
Sys.localeconv()
```

Details

Normally R is run without looking at the value of `LC_NUMERIC`, so the decimal point remains `'.'`. So the first three of these components will only be useful if you have set the locale category `LC_NUMERIC` using `Sys.setlocale` in the current R session (when R may not work correctly).

The monetary components will only be set to non-default values (see the ‘Examples’ section) if the `LC_MONETARY` category is set. It often is not set: set the examples for how to trigger setting it.

Value

A character vector with 18 named components. See your ISO C documentation for details of the meaning.

It is possible to compile R without support for locales, in which case the value will be `NULL`.

See Also

[Sys.setlocale](#) for ways to set locales.

Examples

```
Sys.localeconv()
## The results in the C locale are
##   decimal_point thousands_sep grouping int_curr_symbol
##   " ." " " " " " "
##   currency_symbol mon_decimal_point mon_thousands_sep mon_grouping
##   " " " " " " " "
##   positive_sign negative_sign int_frac_digits frac_digits
##   " " " " "127" "127"
##   p_cs_precedes p_sep_by_space n_cs_precedes n_sep_by_space
##   "127" "127" "127" "127"
##   p_sign_posn n_sign_posn
##   "127" "127"

## Now try your default locale (which might be "C").
old <- Sys.getlocale()
## The category may not be set:
## the following may do so, but it might not be supported.
Sys.setlocale("LC_MONETARY", locale = "")
Sys.localeconv()
## or set an appropriate value yourself, e.g.
Sys.setlocale("LC_MONETARY", "de_AT")
```

```

Sys.localeconv()
Sys.setlocale(locale = old)

## Not run: read.table("foo", dec=Sys.localeconv()["decimal_point"])

```

sys.parent

Functions to Access the Function Call Stack

Description

These functions provide access to [environments](#) ('frames' in S terminology) associated with functions further up the calling stack.

Usage

```

sys.call(which = 0)
sys.frame(which = 0)
sys.nframe()
sys.function(which = 0)
sys.parent(n = 1)

sys.calls()
sys.frames()
sys.parents()
sys.on.exit()
sys.status()
parent.frame(n = 1)

```

Arguments

<code>which</code>	the frame number if non-negative, the number of frames to go back if negative.
<code>n</code>	the number of generations to go back. (See the 'Details' section.)

Details

[.GlobalEnv](#) is given number 0 in the list of frames. Each subsequent function evaluation increases the frame stack by 1. The call, function definition and the environment for evaluation of that function are returned by `sys.call`, `sys.function` and `sys.frame` with the appropriate index.

`sys.call`, `sys.function` and `sys.frame` accept integer values for the argument `which`. Non-negative values of `which` are frame numbers starting from [.GlobalEnv](#) whereas negative values are counted back from the frame number of the current evaluation.

The parent frame of a function evaluation is the environment in which the function was called. It is not necessarily numbered one less than the frame number of the current evaluation, nor is it the environment within which the function was defined. `sys.parent` returns the number of the parent frame if `n` is 1 (the default), the grandparent if `n` is 2, and so on. See also the 'Note'.

`sys.nframe` returns an integer, the number of the current frame as described in the first paragraph.

`sys.calls` and `sys.frames` give a pairlist of all the active calls and frames, respectively, and `sys.parents` returns an integer vector of indices of the parent frames of each of those frames.

Notice that even though the `sys.xxx` functions (except `sys.status`) are interpreted, their contexts are not counted nor are they reported. There is no access to them.

`sys.status()` returns a list with components `sys.calls`, `sys.parents` and `sys.frames`, the results of calls to those three functions (which will include the call to `sys.status`: see the first example).

`sys.on.exit()` returns the expression stored for use by `on.exit` in the function currently being evaluated. (Note that this differs from S, which returns a list of expressions for the current frame and its parents.)

`parent.frame(n)` is a convenient shorthand for `sys.frame(sys.parent(n))` (implemented slightly more efficiently).

Value

`sys.call` returns a call, `sys.function` a function definition, and `sys.frame` and `parent.frame` return an environment.

For the other functions, see the ‘Details’ section.

Note

Strictly, `sys.parent` and `parent.frame` refer to the *context* of the parent interpreted function. So internal functions (which may or may not set contexts and so may or may not appear on the call stack) may not be counted, and S3 methods can also do surprising things.

As an effect of lazy evaluation, these functions look at the call stack at the time they are evaluated, not at the time they are called. Passing calls to them as function arguments is unlikely to be a good idea, but these functions still look at the call stack and count frames from the frame of the function evaluation from which they were called.

Hence, when these functions are called to provide default values for function arguments, they are evaluated in the evaluation of the called function and they count frames accordingly (see e.g. the `envir` argument of `eval`).

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X. (Not `parent.frame`.)

See Also

`eval` for a usage of `sys.frame` and `parent.frame`.

Examples

```
require(utils)

## Note: the first two examples will give different results
## if run by example().
ff <- function(x) gg(x)
gg <- function(y) sys.status()
str(ff(1))

gg <- function(y) {
  ggg <- function() {
    cat("current frame is", sys.nframe(), "\n")
    cat("parents are", sys.parents(), "\n")
  }
}
```

```

        print(sys.function(0)) # ggg
        print(sys.function(2)) # gg
    }
    if(y > 0) gg(y-1) else ggg()
}
gg(3)

t1 <- function() {
  aa <- "here"
  t2 <- function() {
    ## in frame 2 here
    cat("current frame is", sys.nframe(), "\n")
    str(sys.calls()) ## list with two components t1() and t2()
    cat("parents are frame numbers", sys.parents(), "\n") ## 0 1
    print(ls(envir = sys.frame(-1))) ## [1] "aa" "t2"
    invisible()
  }
  t2()
}
t1()

test.sys.on.exit <- function() {
  on.exit(print(1))
  ex <- sys.on.exit()
  str(ex)
  cat("exiting...\n")
}
test.sys.on.exit()
## gives 'language print(1)', prints 1 on exit

## An example where the parent is not the next frame up the stack
## since method dispatch uses a frame.
as.double.foo <- function(x)
{
  str(sys.calls())
  print(sys.frames())
  print(sys.parents())
  print(sys.frame(-1)); print(parent.frame())
  x
}
t2 <- function(x) as.double(x)
a <- structure(pi, class = "foo")
t2(a)

```

Description

Find out if a file path is a symbolic link, and if so what it is linked to, *via* the system call `readlink`.

Symbolic links are a POSIX concept, not implemented on Windows but for most filesystems on Unix-alikes.

Usage

```
Sys.readlink(paths)
```

Arguments

`paths` character vector of file paths. Tilde expansion is done: see [path.expand](#).

Value

A character vector of the same length as `paths`. The entries are the path of the file linked to, "" if the path is not a symbolic link, and NA if there is an error (e.g., the path does not exist or cannot be converted to the native encoding).

On platforms without the `readlink` system call, all elements are "".

See Also

[file.symlink](#) for the creation of symbolic links (and their Windows analogues), [file.info](#)

Examples

```
##' To check if files (incl. directories) are symbolic links:
is.symlink <- function(paths) isTRUE(nzchar(Sys.readlink(paths), keepNA=TRUE))
## will return all FALSE when the platform has no `readlink` system call.
is.symlink("/foo/bar")
```

Sys.setenv

Set or Unset Environment Variables

Description

`Sys.setenv` sets environment variables (for other processes called from within R or future calls to [Sys.getenv](#) from this R process).

`Sys.unsetenv` removes environment variables.

Usage

```
Sys.setenv(...)
```

```
Sys.unsetenv(x)
```

Arguments

`...` named arguments with values coercible to a character string.

`x` a character vector, or an object coercible to character.

Details

Non-standard R names must be quoted in `Sys.setenv`: see the examples. Most platforms (and POSIX) do not allow names containing `"=`". Windows does, but the facilities provided by R may not handle these correctly so they should be avoided. Most platforms allow setting an environment variable to `" "`, but Windows does not and there `Sys.setenv(FOO = " ")` unsets FOO.

There may be system-specific limits on the maximum length of the values of individual environment variables or of names+values of all environment variables.

Recent versions of Windows have a maximum length of 32,767 characters for an environment variable; however `cmd.exe` has a limit of 8192 characters for a command line, hence `set` can only set 8188.

Value

A logical vector, with elements being true if (un)setting the corresponding variable succeeded. (For `Sys.unsetenv` this includes attempting to remove a non-existent variable.)

Note

On Unix-alikes, if `Sys.unsetenv` is not supported, it will at least try to set the value of the environment variable to `" "`, with a warning.

See Also

[Sys.getenv](#), [Startup](#) for ways to set environment variables for the R session.

[setwd](#) for the working directory.

[Sys.setlocale](#) to set (and get) language locale variables, and notably [Sys.setLanguage](#) to set the `LANGUAGE` environment variable which is used for [conditionMessage](#) translations.

The help for [‘environment variables’](#) lists many of the environment variables used by R.

Examples

```
print(Sys.setenv(R_TEST = "testit", "A+C" = 123)) # `A+C` could also be used
Sys.getenv("R_TEST")
Sys.unsetenv("R_TEST") # on Unix-alike may warn and not succeed
Sys.getenv("R_TEST", unset = NA)
```

<code>Sys.setFileTime</code>	<i>Set File Time</i>
------------------------------	----------------------

Description

Uses system calls to set the times on a file or directory.

Usage

```
Sys.setFileTime(path, time)
```

Arguments

<code>path</code>	A character vector containing file or directory paths.
<code>time</code>	A date-time of class " <code>POSIXct</code> " or an object which can be coerced to one. Fractions of a second may be ignored. Recycled along <code>paths</code> .

Details

This attempts sets the file time to the value specified.

On a Unix-alike it uses the system call `utimensat` if that is available, otherwise `utimes` or `utime`. On a POSIX file system it sets both the last-access and modification times. Fractional seconds will set as from R 3.4.0 on OSES with the requisite system calls and suitable filesystems.

On Windows it uses the system call `SetFileTime` to set the 'last write time'. Some Windows file systems only record the time at a resolution of two seconds.

`Sys.setFileTime` has been vectorized in R 3.6.0. Earlier versions of R required `path` and `time` to be vectors of length one.

Value

A logical vector indicating if the operation succeeded for each of the files and directories attempted, returned invisibly.

Sys.sleep

Suspend Execution for a Time Interval

Description

Suspend execution of R expressions for a specified time interval.

Usage

```
Sys.sleep(time)
```

Arguments

<code>time</code>	The time interval to suspend execution for, in seconds.
-------------------	---

Details

Using this function allows R to temporarily be given very low priority and hence not to interfere with more important foreground tasks. A typical use is to allow a process launched from R to set itself up and read its input files before R execution is resumed.

The intention is that this function suspends execution of R expressions but wakes the process up often enough to respond to GUI events, typically every half second. It can be interrupted (e.g. by 'Ctrl-C' or 'Esc' at the R console).

There is no guarantee that the process will sleep for the whole of the specified interval (sleep might be interrupted), and it may well take slightly longer in real time to resume execution.

`time` must be non-negative (and not NA nor NaN): `Inf` is allowed (and might be appropriate if the intention is to wait indefinitely for an interrupt). The resolution of the time interval is system-dependent, but will normally be 20ms or better. (On modern Unix-alikes it will be better than 1ms.)

Value

Invisible NULL.

Note

Despite its name, this is not currently implemented using the `sleep` system call (although on Windows it does make use of `Sleep`).

Examples

```
testit <- function(x)
{
  p1 <- proc.time()
  Sys.sleep(x)
  proc.time() - p1 # The cpu usage should be negligible
}
testit(3.7)
```

sys.source

Parse and Evaluate Expressions from a File

Description

Parses expressions in the given file, and then successively evaluates them in the specified environment.

Usage

```
sys.source(file, envir = baseenv(), chdir = FALSE,
           keep.source = getOption("keep.source.pkgs"),
           keep.parse.data = getOption("keep.parse.data.pkgs"),
           toplevel.env = as.environment(envir))
```

Arguments

<code>file</code>	a character string naming the file to be read from.
<code>envir</code>	an R object specifying the environment in which the expressions are to be evaluated. May also be a list or an integer. The default <code>baseenv()</code> corresponds to evaluation in the base environment. This is probably not what you want; you should typically supply an explicit <code>envir</code> argument, see the ‘Note’.
<code>chdir</code>	logical; if <code>TRUE</code> , the R working directory is changed to the directory containing <code>file</code> for evaluating.
<code>keep.source</code>	logical. If <code>TRUE</code> , functions keep their source including comments, see options (<code>keep.source = *</code>) for more details.
<code>keep.parse.data</code>	logical. If <code>TRUE</code> and <code>keep.source</code> is also <code>TRUE</code> , functions keep parse data with their source, see options (<code>keep.parse.data = *</code>) for more details.
<code>toplevel.env</code>	an R environment to be used as top level while evaluating the expressions. This argument is useful for frameworks running package tests; the default should be used in other cases.

Details

For large files, `keep.source = FALSE` may save quite a bit of memory. Disabling only parse data via `keep.parse.data = FALSE` can already save a lot.

Note on `envir`

In order for the code being evaluated to use the correct environment (for example, in global assignments), source code in packages should call `topenv()`, which will return the namespace, if any, the environment set up by `sys.source`, or the global environment if a saved image is being used.

See Also

`source`, and `loadNamespace` which is called from `library(.)` and uses `sys.source(.)`.

Examples

```
## a simple way to put some objects in an environment
## high on the search path
tmp <- tempfile()
writeLines("aaa <- pi", tmp)
env <- attach(NULL, name = "myenv")
sys.source(tmp, env)
unlink(tmp)
search()
aaa
detach("myenv")
```

Sys.time

Get Current Date and Time

Description

`Sys.time` and `Sys.Date` returns the system's idea of the current date with and without time.

Usage

```
Sys.time()
Sys.Date()
```

Details

`Sys.time` returns an absolute date-time value which can be converted to various time zones and may return different days.

`Sys.Date` returns the current day in the current [time zone](#).

Value

`Sys.time` returns an object of class `"POSIXct"` (see [DateTimeClasses](#)). On almost all systems it will have sub-second accuracy, possibly microseconds or better. On Windows it increments in clock ticks (usually 1/60 of a second) reported to millisecond accuracy.

`Sys.Date` returns an object of class `"Date"` (see [Date](#)).

Note

`Sys.time` may return fractional seconds, but they are ignored by the default conversions (e.g., printing) for class "POSIXct". See the examples and `format.POSIXct` for ways to reveal them.

See Also

`date` for the system time in a fixed-format character string.

`Sys.timezone`.

`system.time` for measuring elapsed/CPU time of expressions.

Examples

```
Sys.time()
## print with possibly greater accuracy:
op <- options(digits.secs = 6)
Sys.time()
options(op)

## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y")

Sys.Date()
```

Sys.which

Find Full Paths to Executables

Description

This is an interface to the system command `which`, or to an emulation on Windows.

Usage

```
Sys.which(names)
```

Arguments

`names` Character vector of names or paths of possible executables.

Details

The system command `which` reports on the full path names of an executable (including an executable script) as would be executed by a shell, accepting either absolute paths or looking on the path.

On Windows an ‘executable’ is a file with extension ‘.exe’, ‘.com’, ‘.cmd’ or ‘.bat’. Such files need not actually be executable, but they are what `system` tries.

On a Unix-like the full path to `which` (usually ‘/usr/bin/which’) is found when R is installed.

Value

A character vector of the same length as `names`, named by `names`. The elements are either the full path to the executable or some indication that no executable of that name was found. Typically the indication is "", but this does depend on the OS (and the known exceptions are changed to ""). Missing values in `names` have missing return values.

On Windows the paths will be short paths (8+3 components, no spaces) with \ as the path delimiter.

Note

Except on Windows this calls the system command `which`: since that is not part of e.g. the POSIX standards, exactly what it does is OS-dependent. It will usually do tilde-expansion and it may make use of `cs` aliases.

Examples

```
## the first two are likely to exist everywhere
## texi2dvi exists on most Unix-alikes but not under MiKTeX
Sys.which(c("ftp", "ping", "texi2dvi", "this-does-not-exist"))
```

system	<i>Invoke a System Command</i>
--------	--------------------------------

Description

`system` invokes the OS command specified by `command`.

Usage

```
system(command, intern = FALSE,
        ignore.stdout = FALSE, ignore.stderr = FALSE,
        wait = TRUE, input = NULL, show.output.on.console = TRUE,
        minimized = FALSE, invisible = TRUE, timeout = 0,
        receive.console.signals = wait)
```

Arguments

<code>command</code>	the system command to be invoked, as a character string.
<code>intern</code>	a logical (not NA) which indicates whether to capture the output of the command as an R character vector.
<code>ignore.stdout</code> , <code>ignore.stderr</code>	a logical (not NA) indicating whether messages written to ‘stdout’ or ‘stderr’ should be ignored.
<code>wait</code>	a logical (not NA) indicating whether the R interpreter should wait for the command to finish, or run it asynchronously. This will be ignored (and the interpreter will always wait) if <code>intern = TRUE</code> . When running the command asynchronously, no output will be displayed on the Rgui console in Windows (it will be dropped, instead).
<code>input</code>	if a character vector is supplied, this is copied one string per line to a temporary file, and the standard input of <code>command</code> is redirected to the file.

`timeout` timeout in seconds, ignored if 0. This is a limit for the elapsed time running command in a separate process. Fractions of seconds are ignored.

`receive.console.signals` a logical (not NA) indicating whether the command should receive events from the terminal/console that R runs from, particularly whether it should be interrupted by *Ctrl-C*. This will be ignored and events will always be received when `intern = TRUE` or `wait = TRUE`.

`show.output.on.console,minimized,invisible` arguments that are accepted on Windows but ignored on this platform, with a warning.

Details

This interface has become rather complicated over the years: see [system2](#) for a more portable and flexible interface which is recommended for new code.

`command` is parsed as a command plus arguments separated by spaces. So if the path to the command (or a single argument such as a file path) contains spaces, it must be quoted e.g. by [shQuote](#). Unix-alikes pass the command line to a shell (normally `/bin/sh`, and POSIX requires that shell), so `command` can be anything the shell regards as executable, including shell scripts, and it can contain multiple commands separated by `;`.

On Windows, `system` does not use a shell and there is a separate function `shell` which passes command lines to a shell.

If `intern` is `TRUE` then `popen` is used to invoke the command and the output collected, line by line, into an R [character](#) vector. If `intern` is `FALSE` then the C function `system` is used to invoke the command.

`wait` is implemented by appending `&` to the command: this is in principle shell-dependent, but required by POSIX and so widely supported.

When `timeout` is non-zero, the command is terminated after the given number of seconds. The termination works for typical commands, but is not guaranteed: it is possible to write a program that would keep running after the time is out. Timeouts can only be set with `wait = TRUE`.

Timeouts cannot be used with interactive commands: the command is run with standard input redirected from `/dev/null` and it must not modify terminal settings. As long as `tty tostop` option is disabled, which it usually is by default, the executed command may write to standard output and standard error. One cannot rely on that the execution time of the child processes will be included into `user.child` and `sys.child` element of `proc_time` returned by `proc.time`. For the time to be included, all child processes have to be waited for by their parents, which has to be implemented in the parent applications.

The ordering of arguments after the first two has changed from time to time: it is recommended to name all arguments after the first.

There are many pitfalls in using `system` to ascertain if a command can be run — [Sys.which](#) is more suitable.

`receive.console.signals = TRUE` is useful when running asynchronous processes (using `wait = FALSE`) to implement a synchronous operation. In all other cases it is recommended to use the default.

Value

If `intern = TRUE`, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 bytes will be split on some systems.) If the command could not be run an R error is generated. If `command` runs but gives a non-zero exit status this will be

reported with a warning and in the attribute "status" of the result: an attribute "errmsg" may also be available.

If `intern = FALSE`, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127 and a warning is issued (as from R 3.5.0). Otherwise if `wait = TRUE` the value is the exit status returned by the command, and if `wait = FALSE` it is 0 (the conventional success value).

If the command times out, a warning is reported and the exit status is 124.

Stdout and stderr

For command-line R, error messages written to 'stderr' will be sent to the terminal unless `ignore.stderr = TRUE`. They can be captured (in the most likely shells) by

```
system("some command 2>&1", intern = TRUE)
```

For GUIs, what happens to output sent to 'stdout' or 'stderr' if `intern = FALSE` is interface-specific, and it is unsafe to assume that such messages will appear on a GUI console (they do on the macOS GUI's console, but not on some others).

Differences between Unix and Windows

How processes are launched differs fundamentally between Windows and Unix-alike operating systems, as do the higher-level OS functions on which this R function is built. So it should not be surprising that there are many differences between OSes in how `system` behaves. For the benefit of programmers, the more important ones are summarized in this section.

- The most important difference is that on a Unix-alike `system` launches a shell which then runs `command`. On Windows the command is run directly – use `shell` for an interface which runs `command` *via* a shell (by default the Windows shell `cmd.exe`, which has many differences from a POSIX shell).

This means that it cannot be assumed that redirection or piping will work in `system` (redirection sometimes does, but we have seen cases where it stopped working after a Windows security patch), and `system2` (or `shell`) must be used on Windows.

- What happens to `stdout` and `stderr` when not captured depends on how R is running: Windows batch commands behave like a Unix-alike, but from the Windows GUI they are generally lost. `system(intern = TRUE)` captures 'stderr' when run from the Windows GUI console unless `ignore.stderr = TRUE`.
- The behaviour on error is different in subtle ways (and has differed between R versions).
- The quoting conventions for `command` differ, but `shQuote` is a portable interface.
- Arguments `show.output.on.console`, `minimized`, `invisible` only do something on Windows (and are most relevant to Rgui there).

See Also

`man system` and `man sh` for how this is implemented on the OS in use.

`.Platform` for platform-specific variables.

`pipe` to set up a pipe connection.

Examples

```
# list all files in the current directory using the -F flag
## Not run: system("ls -F")

# t1 is a character vector, each element giving a line of output from who
# (if the platform has who)
t1 <- try(system("who", intern = TRUE))

try(system("ls fizzlipuzzli", intern = TRUE, ignore.stderr = TRUE))
# zero-length result since file does not exist, and will give warning.
```

system.file

*Find Names of R System Files***Description**

Finds the full file names of files in packages etc.

Usage

```
system.file(..., package = "base", lib.loc = NULL,
            mustWork = FALSE)
```

Arguments

<code>...</code>	character vectors, specifying subdirectory and file(s) within some package. The default, none, returns the root of the package. Wildcards are not supported.
<code>package</code>	a character string with the name of a single package. An error occurs if more than one package name is given.
<code>lib.loc</code>	a character vector with path names of R libraries. See ‘Details’ for the meaning of the default value of NULL.
<code>mustWork</code>	logical. If TRUE, an error is given if there are no matching files.

Details

This checks the existence of the specified files with `file.exists`. So file paths are only returned if there are sufficient permissions to establish their existence.

The unnamed arguments in `...` are usually character strings, but if character vectors they are recycled to the same length.

This uses `find.package` to find the package, and hence with the default `lib.loc = NULL` looks first for attached packages then in each library listed in `.libPaths()`. Note that if a namespace is loaded but the package is not attached, this will look only on `.libPaths()`.

Value

A character vector of positive length, containing the file paths that matched `...`, or the empty string, "", if none matched (unless `mustWork = TRUE`).

If matching the root of a package, there is no trailing separator.

`system.file()` with no arguments gives the root of the **base** package.

See Also

[R.home](#) for the root directory of the R installation, [list.files](#).

[Sys.glob](#) to find paths via wildcards.

Examples

```
system.file()           # The root of the 'base' package
system.file(package = "stats") # The root of package 'stats'
system.file("INDEX")
system.file("help", "AnIndex", package = "splines")
```

system.time	<i>CPU Time Used</i>
-------------	----------------------

Description

Return CPU (and other) times that `expr` used.

Usage

```
system.time(expr, gcFirst = TRUE)
```

Arguments

<code>expr</code>	Valid R expression to be timed.
<code>gcFirst</code>	Logical - should a garbage collection be performed immediately before the timing? Default is TRUE.

Details

`system.time` calls the function [proc.time](#), evaluates `expr`, and then calls `proc.time` once more, returning the difference between the two `proc.time` calls.

`unix.time` has been an alias of `system.time`, for compatibility with S, has been deprecated in 2016 and finally became defunct in 2022.

Timings of evaluations of the same expression can vary considerably depending on whether the evaluation triggers a garbage collection. When `gcFirst` is TRUE a garbage collection ([gc](#)) will be performed immediately before the evaluation of `expr`. This will usually produce more consistent timings.

Value

A object of class "`proc_time`": see [proc.time](#) for details.

See Also

[proc.time](#), [time](#) which is for time series.

[setTimeLimit](#) to limit the (CPU/elapsed) time R is allowed to use.

[Sys.time](#) to get the current date & time.

Examples

```
require(stats)
system.time(for(i in 1:100) mad(runif(1000)))
## Not run:
exT <- function(n = 10000) {
  # Purpose: Test if system.time works ok;   n: loop size
  system.time(for(i in 1:n) x <- mean(rt(1000, df = 4)))
}
#-- Try to interrupt one of the following (using Ctrl-C / Escape):
exT()           #- about 4 secs on a 2.5GHz Xeon
system.time(exT())  #- +/- same

## End(Not run)
```

system2

Invoke a System Command

Description

system2 invokes the OS command specified by `command`.

Usage

```
system2(command, args = character(),
        stdout = "", stderr = "", stdin = "", input = NULL,
        env = character(), wait = TRUE,
        minimized = FALSE, invisible = TRUE, timeout = 0,
        receive.console.signals = wait)
```

Arguments

<code>command</code>	the system command to be invoked, as a character string.
<code>args</code>	a character vector of arguments to <code>command</code> . The arguments have to be quoted e.g. by shQuote in case they contain space or other special characters (a double quote or backslash on Windows, shell-specific special characters on Unix).
<code>stdout, stderr</code>	where output to ‘ <code>stdout</code> ’ or ‘ <code>stderr</code> ’ should be sent. Possible values are “”, to the R console (the default), <code>NULL</code> or <code>FALSE</code> (discard output), <code>TRUE</code> (capture the output in a character vector) or a character string naming a file.
<code>stdin</code>	should input be diverted? “” means the default, alternatively a character string naming a file. Ignored if <code>input</code> is supplied.
<code>input</code>	if a character vector is supplied, this is copied one string per line to a temporary file, and the standard input of <code>command</code> is redirected to the file.
<code>env</code>	character vector of <code>name=value</code> strings to set environment variables.
<code>wait</code>	a logical (not <code>NA</code>) indicating whether the R interpreter should wait for the command to finish, or run it asynchronously. This will be ignored (and the interpreter will always wait) if <code>stdout = TRUE</code> or <code>stderr = TRUE</code> . When running the command asynchronously, no output will be displayed on the Rgui console in Windows (it will be dropped, instead).

<code>timeout</code>	timeout in seconds, ignored if 0. This is a limit for the elapsed time running command in a separate process. Fractions of seconds are ignored.
<code>receive.console.signals</code>	a logical (not NA) indicating whether the command should receive events from the terminal/console that R runs from, particularly whether it should be interrupted by <i>Ctrl-C</i> . This will be ignored and events will always be received when <code>intern = TRUE</code> or <code>wait = TRUE</code> .
<code>minimized, invisible</code>	arguments that are accepted on Windows but ignored on this platform, with a warning.

Details

Unlike `system`, `command` is always quoted by `shQuote`, so it must be a single command without arguments.

For details of how `command` is found see `system`.

On Windows, `env` is only supported for commands such as R and `make` which accept environment variables on their command line.

Some Unix commands (such as some implementations of `ls`) change their output if they consider it to be piped or redirected: `stdout = TRUE` uses a pipe whereas `stdout = "some_file_name"` uses redirection.

Because of the way it is implemented, on a Unix-alike `stderr = TRUE` implies `stdout = TRUE`: a warning is given if this is not what was specified.

When `timeout` is non-zero, the command is terminated after the given number of seconds. The termination works for typical commands, but is not guaranteed: it is possible to write a program that would keep running after the time is out. Timeouts can only be set with `wait = TRUE`.

Timeouts cannot be used with interactive commands: the command is run with standard input redirected from `/dev/null` and it must not modify terminal settings. As long as `tty tostop` option is disabled, which it usually is by default, the executed command may write to standard output and standard error.

`receive.console.signals = TRUE` is useful when running asynchronous processes (using `wait = FALSE`) to implement a synchronous operation. In all other cases it is recommended to use the default.

Value

If `stdout = TRUE` or `stderr = TRUE`, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 bytes will be split.) If the command could not be run an R error is generated. If `command` runs but gives a non-zero exit status this will be reported with a warning and in the attribute `"status"` of the result: an attribute `"errmsg"` may also be available.

In other cases, the return value is an error code (0 for success), given the `invisible` attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127 and a warning is issued (as from R 3.5.0). Otherwise if `wait = TRUE` the value is the exit status returned by the command, and if `wait = FALSE` it is 0 (the conventional success value).

If the command times out, a warning is issued and the exit status is 124.

Note

`system2` is a more portable and flexible interface than `system`. It allows redirection of output without needing to invoke a shell on Windows, a portable way to set environment variables for the execution of `command`, and finer control over the redirection of `stdout` and `stderr`. Conversely, `system` (and `shell` on Windows) allows the invocation of arbitrary command lines.

There is no guarantee that if `stdout` and `stderr` are both `TRUE` or the same file that the two streams will be interleaved in order. This depends on both the buffering used by the command and the OS.

See Also

`system`.

t

Matrix Transpose

Description

Given a matrix or `data.frame` `x`, `t` returns the transpose of `x`.

Usage

```
t(x)
```

Arguments

`x` a matrix or data frame, typically.

Details

This is a generic function for which methods can be written. The description here applies to the default and `"data.frame"` methods.

A data frame is first coerced to a matrix: see `as.matrix`. When `x` is a vector, it is treated as a column, i.e., the result is a 1-row matrix.

Value

A matrix, with `dim` and `dimnames` constructed appropriately from those of `x`, and other attributes except names copied across.

Note

The *conjugate* transpose of a complex matrix A , denoted A^H or A^* , is computed as `Conj(t(A))`.

References

See Also

`aperm` for permuting the dimensions of arrays.

Examples

```
a <- matrix(1:30, 5, 6)
ta <- t(a) ##-- i.e., a[i, j] == ta[j, i] for all i, j :
for(j in seq(ncol(a)))
  if(! all(a[, j] == ta[j, ])) stop("wrong transpose")
```

table

Cross Tabulation and Table Creation

Description

`table` uses cross-classifying factors to build a contingency table of the counts at each combination of factor levels.

Usage

```
table(...,
  exclude = if (useNA == "no") c(NA, NaN),
  useNA = c("no", "ifany", "always"),
  dnn = list.names(...), deparse.level = 1)

as.table(x, ...)
is.table(x)

## S3 method for class 'table'
as.data.frame(x, row.names = NULL, ...,
  responseName = "Freq", stringsAsFactors = TRUE,
  sep = "", base = list(LETTERS))
```

Arguments

<code>...</code>	one or more objects which can be interpreted as factors (including numbers or character strings), or a <code>list</code> (such as a data frame) whose components can be so interpreted. (For <code>as.table</code> , arguments passed to specific methods; for <code>as.data.frame</code> , unused.)
<code>exclude</code>	levels to remove for all factors in <code>...</code> . If it does not contain <code>NA</code> and <code>useNA</code> is not specified, it implies <code>useNA = "ifany"</code> . See ‘Details’ for its interpretation for non-factor arguments.
<code>useNA</code>	whether to include NA values in the table. See ‘Details’. Can be abbreviated.
<code>dnn</code>	the names to be given to the dimensions in the result (the <i>dimnames names</i>).
<code>deparse.level</code>	controls how the default <code>dnn</code> is constructed. See ‘Details’.
<code>x</code>	an arbitrary R object, or an object inheriting from class <code>"table"</code> for the <code>as.data.frame</code> method. Note that <code>as.data.frame.table(x, *)</code> may be called explicitly for non-table <code>x</code> for “reshaping” arrays.
<code>row.names</code>	a character vector giving the row names for the data frame.
<code>responseName</code>	the name to be used for the column of table entries, usually counts.
<code>stringsAsFactors</code>	logical: should the classifying factors be returned as factors (the default) or character vectors?
<code>sep, base</code>	passed to <code>provideDimnames</code> .

Details

If the argument `dnn` is not supplied, the internal function `list.names` is called to compute the ‘dimname names’ as follows: If `...` is one `list` with its own `names()`, these names are used. Otherwise, if the arguments in `...` are named, those names are used. For the remaining arguments, `deparse.level = 0` gives an empty name, `deparse.level = 1` uses the supplied argument if it is a symbol, and `deparse.level = 2` will deparse the argument.

Only when `exclude` is specified (i.e., not by default) and non-empty, will `table` potentially drop levels of factor arguments.

`useNA` controls if the table includes counts of NA values: the allowed values correspond to never ("no"), only if the count is positive ("ifany") and even for zero counts ("always"). Note the somewhat “pathological” case of two different kinds of NAs which are treated differently, depending on both `useNA` and `exclude`, see `d.patho` in the ‘Examples:’ below.

Both `exclude` and `useNA` operate on an “all or none” basis. If you want to control the dimensions of a multiway table separately, modify each argument using `factor` or `addNA`.

Non-factor arguments `a` are coerced via `factor(a, exclude=exclude)`. Since R 3.4.0, care is taken *not* to count the excluded values (where they were included in the NA count, previously).

The `summary` method for class "table" (used for objects created by `table` or `xtabs`) which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

Value

`table()` returns a *contingency table*, an object of class "table", an array of integer values. Note that unlike S the result is always an `array`, a 1D array if one factor is given.

`as.table` and `is.table` coerce to and test for contingency table, respectively.

The `as.data.frame` method for objects inheriting from class "table" can be used to convert the array-based representation of a contingency table to a data frame containing the classifying factors and the corresponding entries (the latter as component named by `responseName`). This is the inverse of `xtabs`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`tabulate` is the underlying function and allows finer control.

Use `ftable` for printing (and more) of multidimensional tables. `margin.table`, `prop.table`, `addmargins`.

`addNA` for constructing factors with NA as a level.

`xtabs` for cross tabulation of data frames with a formula interface.

Examples

```
require(stats) # for rpois and xtabs

## Simple frequency distribution
table(rpois(100, 5))
```

```

## Check the design:
with(warpbreaks, table(wool, tension))
table(state.division, state.region)

## Simple two-way contingency table:
with(airquality, table(cut(Temp, quantile(Temp)), Month))

## Dimension names:
a <- letters[1:3]
table(a, sample(a)) # dnn is c("a", "")
table(a, sample(a), dnn = NULL) # dimnames() have no names
table(a, sample(a), deparse.level = 0) # dnn is c("", "")
table(a, sample(a), deparse.level = 2) # dnn is c("a", "sample(a)")

## xtabs() <-> as.data.frame.table() :
UCBAdmissions ## already a contingency table
DF <- as.data.frame(UCBAdmissions)
class(tab <- xtabs(Freq ~ ., DF)) # xtabs & table
## tab *is* "the same" as the original table:
all(tab == UCBAdmissions)
all.equal(dimnames(tab), dimnames(UCBAdmissions))

## Excluding levels:
a <- rep(c(NA, 1/0:3), 10)
table(a) # does not report NAs
table(a, exclude = NULL) # reports NAs
b <- factor(rep(c("A","B","C"), 10))
table(b)
table(b, exclude = "B")
d <- factor(rep(c("A","B","C"), 10), levels = c("A","B","C","D","E"))
table(d, exclude = "B")
print(table(b, d), zero.print = ".")

## NA counting:
is.na(d) <- 3:4
d. <- addNA(d)
d.[1:7]
table(d.) # "", exclude = NULL" is not needed
## i.e., if you want to count the NAs of 'd', use
table(d, useNA = "ifany")

## "pathological" case:
d.patho <- addNA(c(1,NA,1:2,1:3))[-7]; is.na(d.patho) <- 3:4
d.patho
## just 3 consecutive NAs ? --- well, have *two* kinds of NAs here :
as.integer(d.patho) # 1 4 NA NA 1 2
##
## In R >= 3.4.0, table() allows to differentiate:
table(d.patho) # counts the "unusual" NA
table(d.patho, useNA = "ifany") # counts all three
table(d.patho, exclude = NULL) # (ditto)
table(d.patho, exclude = NA) # counts none

## Two-way tables with NA counts. The 3rd variant is absurd, but shows
## something that cannot be done using exclude or useNA.
with(airquality,
     table(OzHi = Ozone > 80, Month, useNA = "ifany"))

```

```
with(airquality,
      table(OzHi = Ozone > 80, Month, useNA = "always"))
with(airquality,
      table(OzHi = Ozone > 80, addNA(Month)))
```

tabulate

Tabulation for Vectors

Description

`tabulate` takes the integer-valued vector `bin` and counts the number of times each integer occurs in it.

Usage

```
tabulate(bin, nbins = max(1, bin), na.rm = TRUE))
```

Arguments

<code>bin</code>	a numeric vector (of positive integers), or a factor. Long vectors are supported.
<code>nbins</code>	the number of bins to be used.

Details

`tabulate` is the workhorse for the [table](#) function.

If `bin` is a factor, its internal integer representation is tabulated.

If the elements of `bin` are numeric but not integers, they are truncated by [as.integer](#).

Value

An integer valued [integer](#) or [double](#) vector (without names). There is a bin for each of the values `1, ..., nbins`; values outside that range and NAs are (silently) ignored.

On 64-bit platforms `bin` can have 2^{31} or more elements (i.e., `length(bin) > .Machine$integer.max`), and hence a count could exceed the maximum integer. For this reason, the return value is of type `double` for such long `bin` vectors.

See Also

[table](#), [factor](#).

Examples

```
tabulate(c(2,3,5))
tabulate(c(2,3,3,5), nbins = 10)
tabulate(c(-2,0,2,3,3,5)) # -2 and 0 are ignored
tabulate(c(-2,0,2,3,3,5), nbins = 3)
tabulate(factor(letters[1:10]))
```

Tailcall	Tailcall <i>and</i> Exec
----------	--------------------------

Description

`Tailcall` and `Exec` allow writing more stack-space-efficient recursive functions in R.

Usage

```
Tailcall(FUN, ...)  
Exec(expr, envir)
```

Arguments

<code>FUN</code>	a function or a non-empty character string naming the function to be called.
<code>...</code>	all the arguments to be passed.
<code>expr</code>	a call expression.
<code>envir</code>	environment for evaluating <code>expr</code> ; default is the environment from which <code>Exec</code> is called.

Details

`Tailcall` evaluates a call to `FUN` with arguments `...` in the current environment, and `Exec` evaluates the call `expr` in environment `envir`. If a `Tailcall` or `Exec` expression appears in tail position in an R function, and if there are no `on.exit` expressions set, then the evaluation context of the new calls replaces the currently executing call context with a new one. If the requirements for context re-use are not met, then evaluation proceeds in the standard way adding another context to the stack.

Using `Tailcall` it is possible to define tail-recursive functions that do not grow the evaluation stack. `Exec` can be used to simplify the call stack for functions that create and then evaluate an expression.

Because of lazy evaluation of arguments in R it may be necessary to force evaluation of some arguments to avoid accumulating deferred evaluations.

This *tail call optimization* has the advantage of not growing the call stack and permitting arbitrarily deep tail recursions. It does also mean that stack traces produced by `traceback` or `sys.calls` will only show the call specified by `Tailcall` or `Exec`, not the previous call whose stack entry has been replaced.

Note

`Tailcall` and `Exec` are experimental and may be changed or dropped in future released versions of R.

[Recall](#) and [force](#).

Examples

```
## tail-recursive log10-factorial
lfact <- function(n) {
  lfact_iter <- function(val, n) {
    if (n <= 0)
      val
    else {
      val <- val + log10(n) # forces val
      Tailcall(lfact_iter, val, n - 1)
    }
  }
  lfact_iter(0, n)
}
10 ^ lfact(3)
lfact(100000)

## simplified variant of do.call using Exec:
docall <- function (what, args, quote = FALSE) {
  if (!is.list(args))
    stop("second argument must be a list")
  if (quote)
    args <- lapply(args, enquote)
  Exec(as.call(c(list(substitute(what)), args)), parent.frame())
}
## the call stack does not contain the call to docall:
docall(function() sys.calls(), list()) |>
  Find(function(x) identical(x[[1]], quote(docall))), x = _)
## contrast to do.call:
do.call(function(x) sys.calls(), list()) |>
  Find(function(x) identical(x[[1]], quote(do.call))), x = _)
```

tapply

Apply a Function Over a Ragged Array

Description

Apply a function to each cell of a ragged array, that is to each (non-empty) group of values or data rows given by a unique combination of the levels of certain factors.

Usage

```
tapply(X, INDEX, FUN = NULL, ..., default = NA, simplify = TRUE)
```

Arguments

X	an R object for which a split method exists. Typically vector-like, allowing subsetting with <code>[</code> , or a data frame.
INDEX	a list of one or more factors , each of same length as X. The elements are coerced to factors by as.factor . Can also be a formula, which is useful if X is a data frame; see the <code>f</code> argument in split for interpretation.

<code>FUN</code>	a function (or name of a function) to be applied, or <code>NULL</code> . In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be backquoted or quoted. If <code>FUN</code> is <code>NULL</code> , <code>tapply</code> returns a vector which can be used to subscript the multi-way array <code>tapply</code> normally produces.
<code>...</code>	optional arguments to <code>FUN</code> ; the Note section.
<code>default</code>	(only in the case of simplification to an array) the value with which the array is initialized as <code>array(default, dim = ...)</code> . Before R 3.4.0, this was hard coded to <code>array()</code> 's default <code>NA</code> . If it is <code>NA</code> (the default), the missing value of the answer type, e.g. <code>NA_real_</code> , is chosen (<code>as.raw(0)</code> for <code>"raw"</code>). In a numerical case, it may be set, e.g., to <code>FUN(integer(0))</code> , e.g., in the case of <code>FUN = sum</code> to 0 or 0L.
<code>simplify</code>	logical; if <code>FALSE</code> , <code>tapply</code> always returns an array of mode <code>"list"</code> ; in other words, a <code>list</code> with a <code>dim</code> attribute. If <code>TRUE</code> (the default), then if <code>FUN</code> always returns a scalar, <code>tapply</code> returns an array with the mode of the scalar.

Details

If `FUN` is not `NULL`, it is passed to `match.fun`, and hence it can be a function or a symbol or character string naming a function.

Value

When `FUN` is present, `tapply` calls `FUN` for each cell that has any data in it. If `FUN` returns a single atomic value for each such cell (e.g., functions `mean` or `var`) and when `simplify` is `TRUE`, `tapply` returns a multi-way `array` containing the values, and `NA` for the empty cells. The array has the same number of dimensions as `INDEX` has components; the number of levels in a dimension is the number of levels (`nlevels()`) in the corresponding component of `INDEX`. Note that if the return value has a class (e.g., an object of class `"Date"`) the class is discarded.

`simplify = TRUE` always returns an array, possibly 1-dimensional.

If `FUN` does not return a single atomic value, `tapply` returns an array of mode `list` whose components are the values of the individual calls to `FUN`, i.e., the result is a list with a `dim` attribute.

When there is an array answer, its `dimnames` are named by the names of `INDEX` and are based on the levels of the grouping factors (possibly after coercion).

For a list result, the elements corresponding to empty cells are `NULL`.

The `array2DF` function can be used to convert the array returned by `tapply` into a data frame, which may be more convenient for further analysis.

Note

Optional arguments to `FUN` supplied by the `...` argument are not divided into cells. It is therefore inappropriate for `FUN` to expect additional arguments with the same length as `X`.

`array2DF` to convert the result into a data frame.

Examples

```
require(stats)
groups <- as.factor(rbinom(32, n = 5, prob = 0.4))
tapply(groups, groups, length) #- is almost the same as
table(groups)

## contingency table from data.frame : array with named dimnames
tapply(warpbreaks$breaks, warpbreaks[, -1], sum)
tapply(warpbreaks$breaks, warpbreaks[, 3, drop = FALSE], sum)

n <- 17; fac <- factor(rep_len(1:3, n), levels = 1:5)
table(fac)
tapply(1:n, fac, sum)
tapply(1:n, fac, sum, default = 0) # maybe more desirable
tapply(1:n, fac, sum, simplify = FALSE)
tapply(1:n, fac, range)
tapply(1:n, fac, quantile)
tapply(1:n, fac, length) ## NAs
tapply(1:n, fac, length, default = 0) # == table(fac)

## example of ... argument: find quarterly means
tapply(presidents, cycle(presidents), mean, na.rm = TRUE)

ind <- list(c(1, 2, 2), c("A", "A", "B"))
table(ind)
tapply(1:3, ind) #-> the split vector
tapply(1:3, ind, sum)

## Some assertions (not held by all patch proposals):
nq <- names(quantile(1:5))
stopifnot(
  identical(tapply(1:3, ind), c(1L, 2L, 4L)),
  identical(tapply(1:3, ind, sum),
    matrix(c(1L, 2L, NA, 3L), 2, dimnames = list(c("1", "2"), c("A", "B")))),
  identical(tapply(1:n, fac, quantile)[-1],
    array(list(`2` = structure(c(2, 5.75, 9.5, 13.25, 17), names = nq),
      `3` = structure(c(3, 6, 9, 12, 15), names = nq),
      `4` = NULL, `5` = NULL), dim=4, dimnames=list(as.character(2:5))))))
```

taskCallback

Add or Remove a Top-Level Task Callback

Description

`addTaskCallback` registers an R function that is to be called each time a top-level task is completed.

`removeTaskCallback` un-registers a function that was registered earlier via `addTaskCallback`.

These provide low-level access to the internal/native mechanism for managing task-completion actions. One can use [taskCallbackManager](#) at the R-language level to manage R functions that are called at the completion of each task. This is easier and more direct.

Usage

```
addTaskCallback(f, data = NULL, name = character())  
removeTaskCallback(id)
```

Arguments

<code>f</code>	the function that is to be invoked each time a top-level task is successfully completed. This is called with 5 or 4 arguments depending on whether <code>data</code> is specified or not, respectively. The return value should be a logical value indicating whether to keep the callback in the list of active callbacks or discard it.
<code>data</code>	if specified, this is the 5-th argument in the call to the callback function <code>f</code> .
<code>id</code>	a string or an integer identifying the element in the internal callback list to be removed. Integer indices are 1-based, i.e the first element is 1. The names of currently registered handlers is available using <code>getTaskCallbackNames()</code> and is also returned in a call to <code>addTaskCallback</code> .
<code>name</code>	character: names to be used.

Details

Top-level tasks are individual expressions rather than entire lines of input. Thus an input line of the form `expression1 ; expression2` will give rise to 2 top-level tasks.

A top-level task callback is called with the expression for the top-level task, the result of the top-level task, a logical value indicating whether it was successfully completed or not (always TRUE at present), and a logical value indicating whether the result was printed or not. If the `data` argument was specified in the call to `addTaskCallback`, that value is given as the fifth argument.

The callback function should return a logical value. If the value is FALSE, the callback is removed from the task list and will not be called again by this mechanism. If the function returns TRUE, it is kept in the list and will be called on the completion of the next top-level task.

Value

`addTaskCallback` returns an integer value giving the position in the list of task callbacks that this new callback occupies. This is only the current position of the callback. It can be used to remove the entry as long as no other values are removed from earlier positions in the list first.

`removeTaskCallback` returns a logical value indicating whether the specified element was removed. This can fail (i.e., return FALSE) if an incorrect name or index is given that does not correspond to the name or position of an element in the list.

Note

There is also C-level access to top-level task callbacks to allow C routines rather than R functions be used.

[getTaskCallbackNames](#), [taskCallbackManager](#)

<https://developer.r-project.org/TaskHandlers.pdf>

Examples

```

times <- function(total = 3, str = "Task a") {
  ctr <- 0
  function(expr, value, ok, visible) {
    ctr <- ctr + 1
    cat(str, ctr, "\n")
    keep.me <- (ctr < total)
    if (!keep.me)
      cat("handler removing itself\n")

    # return
    keep.me
  }
}

# add the callback that will work for
# 4 top-level tasks and then remove itself.
n <- addTaskCallback(times(4))

# now remove it, assuming it is still first in the list.
removeTaskCallback(n)

## See how the handler is called every time till "self destruction":

addTaskCallback(times(4)) # counts as once already

sum(1:10) ; mean(1:3) # two more
sinpi(1)           # 4th - and "done"
cospi(1)
tanpi(1)

```

taskCallbackManager

Create an R-level Task Callback Manager

Description

This provides an entirely R-language mechanism for managing callbacks or actions that are invoked at the conclusion of each top-level task. Essentially, we register a single R function from this manager with the underlying, native task-callback mechanism and this function handles invoking the other R callbacks under the control of the manager. The manager consists of a collection of functions that access shared variables to manage the list of user-level callbacks.

Usage

```

taskCallbackManager(handlers = list(), registered = FALSE,
  verbose = FALSE)

```

Arguments

handlers	this can be a list of callbacks in which each element is a list with an element named "f" which is a callback function, and an optional element named "data" which is the 5-th argument to be supplied to the callback when it is
----------	---

	invoked. Typically this argument is not specified, and one uses <code>add</code> to register callbacks after the manager is created.
<code>registered</code>	a logical value indicating whether the <code>evaluate</code> function has already been registered with the internal task callback mechanism. This is usually <code>FALSE</code> and the first time a callback is added via the <code>add</code> function, the <code>evaluate</code> function is automatically registered. One can control when the function is registered by specifying <code>TRUE</code> for this argument and calling <code>addTaskCallback</code> manually.
<code>verbose</code>	a logical value, which if <code>TRUE</code> , causes information to be printed to the console about certain activities this dispatch manager performs. This is useful for debugging callbacks and the handler itself.

Value

A `list` containing 6 functions:

<code>add()</code>	register a callback with this manager, giving the function, an optional 5-th argument, an optional name by which the callback is stored in the list, and a <code>register</code> argument which controls whether the <code>evaluate</code> function is registered with the internal C-level dispatch mechanism if necessary.
<code>remove()</code>	remove an element from the manager's collection of callbacks, either by name or position/index.
<code>evaluate()</code>	the 'real' callback function that is registered with the C-level dispatch mechanism and which invokes each of the R-level callbacks within this manager's control.
<code>suspend()</code>	a function to set the suspend state of the manager. If it is suspended, none of the callbacks will be invoked when a task is completed. One sets the state by specifying a logical value for the <code>status</code> argument.
<code>register()</code>	a function to register the <code>evaluate</code> function with the internal C-level dispatch mechanism. This is done automatically by the <code>add</code> function, but can be called manually.
<code>callbacks()</code>	returns the list of callbacks being maintained by this manager.

Examples

```
# create the manager
h <- taskCallbackManager()

# add a callback
h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")
```

```
# look at the internal callbacks.
getTaskCallbackNames()

# look at the R-level callbacks
names(h$callbacks())

removeTaskCallback("R-taskCallbackManager")
```

taskCallbackNames *Query the Names of the Current Internal Top-Level Task Callbacks*

Description

This provides a way to get the names (or identifiers) for the currently registered task callbacks that are invoked at the conclusion of each top-level task. These identifiers can be used to remove a callback.

Usage

```
getTaskCallbackNames()
```

Value

A character vector giving the name for each of the registered callbacks which are invoked when a top-level task is completed successfully. Each name is the one used when registering the callbacks and returned as the in the call to [addTaskCallback](#).

Note

One can use [taskCallbackManager](#) to manage user-level task callbacks, i.e., S-language functions, entirely within the S language and access the names more directly.

  return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()

# now remove it by name
removeTaskCallback("simpleHandler")

h <- taskCallbackManager()
h$add(function(expr, value, ok, visible) {
```

```

        cat("In handler\n")
        return(TRUE)
      }, name = "simpleHandler")
getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")

```

tempfile

*Create Names for Temporary Files***Description**

`tempfile` returns a vector of character strings which can be used as names for temporary files.

Usage

```
tempfile(pattern = "file", tmpdir = tmpdir(), fileext = "")
tmpdir(check = FALSE)
```

Arguments

<code>pattern</code>	a non-empty character vector giving the initial part of the name.
<code>tmpdir</code>	a non-empty character vector giving the directory name.
<code>fileext</code>	a non-empty character vector giving the file extension.
<code>check</code>	logical (TRUE or FALSE) indicating if <code>tmpdir()</code> should be checked and recreated if no longer valid.

Details

The length of the result is the maximum of the lengths of the three arguments; values of shorter arguments are recycled.

The names are very likely to be unique among calls to `tempfile` in an R session and across simultaneous R sessions (unless `tmpdir` is specified). The filenames are guaranteed not to be currently in use.

The file name is made by concatenating the path given by `tmpdir`, the `pattern` string, a random string in hex and a suffix of `fileext`.

By default, `tmpdir` will be the directory given by `tmpdir()`. This will be a subdirectory of the per-session temporary directory found by the following rule when the R session is started. The environment variables `TMPDIR`, `TMP` and `TEMP` are checked in turn and the first found which points to a writable directory is used: if none succeeds `"/tmp"` is used. The path must not contain spaces. Note that setting any of these environment variables in the R session has no effect on `tmpdir()`: the per-session temporary directory is created before the interpreter is started.

Value

For `tempfile` a character vector giving the names of possible (temporary) files. Note that no files are generated by `tempfile`.

For `tmpdir`, the path of the per-session temporary directory.

On Windows, both will use a backslash as the path separator.

On a Unix-alike, the value will be an absolute path (unless `tmpdir` is set to a relative path), but it need not be canonical (see [normalizePath](#)) and on macOS it often is not.

Note on parallel use

R processes forked by functions such as `mclapply` and `makeForkCluster` in package **parallel** share a per-session temporary directory. Further, the ‘guaranteed not to be currently in use’ applies only at the time of asking, and two children could ask simultaneously. This is circumvented by ensuring that `tempfile` calls in different children try different names.

Source

The final component of `tempdir()` is created by the POSIX system call `mkdtemp`, or if this is not available (e.g. on Windows) a version derived from the source code of GNU `glibc`.

It will be of the form ‘RtmpXXXXXX’ where the last 6 characters are replaced in a platform-specific way. POSIX only requires that the replacements be ASCII, which allows `.` (so the value may appear to have a file extension) and [regex](#) metacharacters such as `+`. Most commonly the replacements are from the [regex](#) pattern `[A-Za-z0-9]`, but `.` has been seen.

tempfile("plot", fileext = c(".ps", ".pdf"))

tempdir() # works on all platforms with a platform-dependent result

## Show how 'check' is working on some platforms:
if(exists("I'm brave") && `I'm brave` &&
  identical(.Platform$OS.type, "unix") && grepl("^/tmp/", tempdir())) {
  cat("Current tempdir(): ", tempdir(), "\n")
  cat("Removing it :", file.remove(tempdir()),
      "; dir.exists(tempdir()):", dir.exists(tempdir()), "\n")
  cat("and now tempdir(check = TRUE) :", tempdir(check = TRUE), "\n")
}
```

textConnection

Text Connections

Description

Input and output text connections.

Usage

```
textConnection(object, open = "r", local = FALSE,
               name = deparse1(substitute(object)),
               encoding = c("", "bytes", "UTF-8"))

textConnectionValue(con)
```

Arguments

<code>object</code>	character. A description of the connection . For an input this is an R character vector object, and for an output connection the name for the R character vector to receive the output, or <code>NULL</code> (for none).
<code>open</code>	character string. Either <code>"r"</code> (or equivalently <code>" "</code>) for an input connection or <code>"w"</code> or <code>"a"</code> for an output connection.
<code>local</code>	logical. Used only for output connections. If <code>TRUE</code> , output is assigned to a variable in the calling environment. Otherwise the global environment is used.
<code>name</code>	a character string specifying the connection name.
<code>encoding</code>	character string, partially matched. Used only for input connections. How marked strings in <code>object</code> should be handled: converted to the current locale, used byte-by-byte or translated to UTF-8.
<code>con</code>	an output text connection.

Details

An input text connection is opened and the character vector is copied at time the connection object is created, and `close` destroys the copy. `object` should be the name of a character vector: however, short expressions will be accepted provided they [deparse](#) to less than 60 bytes.

An output text connection is opened and creates an R character vector of the given name in the user's workspace or in the calling environment, depending on the value of the `local` argument. This object will at all times hold the completed lines of output to the connection, and `isIncomplete` will indicate if there is an incomplete final line. Closing the connection will output the final line, complete or not. (A line is complete once it has been terminated by end-of-line, represented by `"\n"` in R.) The output character vector has locked bindings (see [lockBinding](#)) until `close` is called on the connection. The character vector can also be retrieved *via* `textConnectionValue`, which is the only way to do so if `object = NULL`. If the current locale is detected as Latin-1 or UTF-8, non-ASCII elements of the character vector will be marked accordingly (see [Encoding](#)).

Opening a text connection with `mode = "a"` will attempt to append to an existing character vector with the given name in the user's workspace or the calling environment. If none is found (even if an object exists of the right name but the wrong type) a new character vector will be created, with a warning.

You cannot `seek` on a text connection, and `seek` will always return zero as the position.

Text connections have slightly unusual semantics: they are always open, and throwing away an input text connection without closing it (so it get garbage-collected) does not give a warning.

Value

For `textConnection`, a connection object of class `"textConnection"` which inherits from class `"connection"`.

For `textConnectionValue`, a character vector.

Note

As output text connections keep the character vector up to date line-by-line, they are relatively expensive to use, and it is often better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

summary(resid(lm.D9))
sink()
close(zz)
cat(foo, sep = "\n")
```

tilde

*Tilde Operator***Description**

Tilde is used to separate the left- and right-hand sides in a model formula.

Usage

```
y ~ model
```

Arguments

y, model symbolic expressions.

Details

The left-hand side is optional, and one-sided formulae are used in some contexts.

A formula has [mode call](#). It can be subsetted by [[: the components are ~, the left-hand side (if present) and the right-hand side *in that order*. (Thus one-sided formulae have two components.)

[formula](#)

timezones

*Time Zones***Description**

Information about time zones in R. `Sys.timezone` returns the name of the current time zone.

Usage

```
Sys.timezone(location = TRUE)
```

```
OlsonNames(tzdir = NULL)
```

Arguments

location logical. Defunct, with a warning if FALSE.

tzdir the time-zone database to be used: the default is to try known locations until one is found.

Details

Time zones are a system-specific topic, but these days almost all R platforms use similar underlying code, used by Linux, macOS, Solaris, AIX and FreeBSD, and installed with R on Windows. (Unfortunately there are many system-specific errors in the implementations.) It is possible to use the R sources' version of the code on Unix-alikes as well as on Windows: this is the default on macOS.

It should be possible to set the current time zone via the environment variable TZ: see the section on 'Time zone names' for suitable values. `Sys.timezone()` will return the value of TZ if set initially (and on some OSes it is always set), otherwise it will try to retrieve from the OS a value which if set for TZ would give the initial time zone. ('Initially' means before any time-zone functions are used: if TZ is being set to override the OS setting or if the 'try' does not get this right, it should be set before the R process is started or (probably early enough) in file `.Rprofile`).

If TZ is set but invalid, most platforms default to 'UTC', the time zone colloquially known as 'GMT' (see https://en.wikipedia.org/wiki/Coordinated_Universal_Time). (Some but not all platforms will give a warning for invalid values.) If it is unset or empty the *system* time zone is used (the one returned by `Sys.timezone`).

Time zones did not come into use until the middle of the nineteenth century and were not widely adopted until the twentieth, and *daylight saving time* (DST, also known as *summer time*) was first introduced in the early twentieth century, most widely in 1916. Over the last 100 years places have changed their affiliation between major time zones, have opted out of (or in to) DST in various years or adopted DST rule changes late or not at all. (For example, the UK experimented with DST throughout 1971, only.) In a few countries (one is the Irish Republic) it is the summer time which is the 'standard' time and a different name is used in winter. And there can be multiple changes during a year, for example for Ramadan.

A quite common system implementation of POSIXct was as signed 32-bit integers and so only went back to the end of 1901: on such systems R assumes that dates prior to that are in the same time zone as they were in 1902. Most of the world had not adopted time zones by 1902 (so used local 'mean time' based on longitude) but for a few places there had been time-zone changes before then. 64-bit representations are becoming by far the most common; unfortunately on some 64-bit OSes the database information is 32-bit and so only available for the range 1901–2038, and incompletely for the end years.

When a time zone location is first found in a session its value is cached in object `.sys.timezone` in the base environment.

Value

`Sys.timezone` returns an OS-specific character string, possibly NA or an empty string (which on some OSes means 'UTC'). This will be a location such as "Europe/London" if one can be ascertained.

A time zone region may be known by several names: for example "Europe/London" may also be known as 'GB', 'GB-Eire', 'Europe/Belfast', 'Europe/Guernsey', 'Europe/Isle_of_Man' and 'Europe/Jersey'. A few regions are also known by a summary of their time zone, e.g. 'PST8PDT' is (on most but not all systems) an alias for 'America/Los_Angeles'.

`OlsonNames` returns a character vector, see the examples for typical cases. It may have an attribute "Version", something like "2023a". (It does on systems using '--with-internal-tzcode' and those like Fedora distributing file 'tzdata.zi'.)

Time zone names

Names "UTC" and its synonym "GMT" are accepted on all platforms.

Where OSes describe their valid time zones can be obscure. The help for the C function `tzset` can be helpful, but it can also be inaccurate. There is a cumbersome POSIX specification (listed under environment variable `TZ` at https://pubs.opengroup.org/onlinepubs/9699919799/basedefs/V1_chap08.html#tag_08), which is often at least partially supported, but there are other more user-friendly ways to specify time zones.

Almost all R platforms make use of a time-zone database originally compiled by Arthur David Olson and now managed by IANA, in which the preferred way to refer to a time zone is by a location (typically of a city), e.g., `Europe/London`, `America/Los_Angeles`, `Pacific/Easter` within a ‘time zone region’. Some traditional designations are also allowed such as `EST5EDT` or `GB`. (Beware that some of these designations may not be what you expect: in particular `EST` is a time zone used in Canada *without* daylight saving time, and not `EST5EDT` nor (Australian) Eastern Standard Time.) The designation can also be an optional colon prepended to the path to a file giving compiled zone information (and the examples above are all files in a system-specific location). See <https://data.iana.org/time-zones/tz-link.html> for more details and references. By convention, regions with a unique time-zone history since 1970 have specific names in the database, but those with different earlier histories may not. Each time zone has one or two (the second for ‘summer’) *abbreviations* used when formatting times.

Increasingly OSes are (optionally or always) not including ‘legacy’ names such as `US/Eastern`: only names of the forms `Continent/City` and `Etc/...` are fully portable.

The abbreviations used have changed over the years: for example France used ‘PMT’ (‘Paris Mean Time’) from 1891 to 1911 then ‘WET/WEST’ up to 1940 and ‘CET/CEST’ from 1946. (In almost all time zones the abbreviations have been stable since 1970.) The POSIX standard allows only one or two abbreviations per time zone, so you may see the current abbreviation(s) used for older times.

For some time zones abbreviations are like ‘-03’ and ‘+0845’: this is done when there is no official abbreviation. (Negative values are behind (West of) UTC, as for the “%z” format for `strftime`.)

The function `OlsonNames` returns the time-zone names known to the currently selected Olson/IANA database. The system-specific location in the file system varies, e.g. `/usr/share/zoneinfo` (Linux, macOS, FreeBSD), `/usr/share/lib/zoneinfo` (Solaris, AIX), It is likely that there is a file named something like ‘zone1970.tab’ or (older) ‘zone.tab’ under that directory listing the locations known as time-zone names (but not for example `EST5EDT`). See also <https://en.wikipedia.org/wiki/Zone.tab>.

Where R was configured with option ‘--with-internal-tzcode’ (the default on Windows), the database at `file.path(R.home("share"), "zoneinfo")` is used by default: file ‘VERSION’ in that directory states the version. That option is also the default on macOS but there whichever is more recent of the system database at `/var/db/timezone/zoneinfo` and that distributed with R is used by default. Environment variable `TZDIR` can be used to give the full path to a different ‘zoneinfo’ database: value `"internal"` indicates the database from the R sources and `"macOS"` indicates the system database. (Setting either of those values would not be recognized by other software using `TZDIR`.)

Setting `TZDIR` is also supported by the native services on some OSes, e.g. Linux using `glibc` except in secure modes.

Time zones given by name (*via* environment variable `TZ`, in `tz` arguments to functions such as `as.POSIXlt` and perhaps the system time zone) are loaded from the currently selected ‘zoneinfo’ database.

On Windows only: An attempt is made (once only per session) to map Windows’ idea of the current time zone to a location, following a version of <http://unicode.org/repos/cldr/trunk/common/supplemental/windowsZones.xml> with additional values deduced from the Windows Registry and documentation. It can be overridden by setting the `TZ` environment variable before any date-times are used in the session.

Most platforms support time zones of the form ‘Etc/GMT+n’ and ‘Etc/GMT-n’ (possibly also without prefix ‘Etc/’), which assume a fixed offset from UTC (hence no DST). Contrary to some expectations (but consistent with names such as ‘PST8PDT’), negative offsets are times ahead of (East of) UTC, positive offsets are times behind (West of) UTC.

Immediately prior to the advent of legislated time zones, most people used time based on their longitude (or that of a nearby town), known as ‘Local Mean Time’ and abbreviated as ‘LMT’ in the databases: in many countries that was codified with a specific name before the switch to a standard time. For example, Paris codified its LMT as ‘Paris Mean Time’ in 1891 (to be used throughout mainland France) and switched to ‘GMT+0’ in 1911.

Some systems (notably Linux) have a `tzselect` command which allows the interactive selection of a supported time zone name. On systems using `systemd` (notably Linux), the OS command `timedatectl list-timezones` will list all available time zone names.

Warnings

There is a system-specific upper limit on the number of bytes in (abbreviated) time-zone names which can be as low as 6 (as required by POSIX). Some OSes allow the setting of time zones with names which exceed their limit, and that can crash the R session.

Information about future times is speculative (‘proleptic’): the database provides the best-known information based on current rules set by civil authorities. For the period 1900–1970 those rules (and which of any authority’s rules were enacted) are often obscure, and the databases do get corrected frequently.

`OlsonNames` tries to find an Olson database in known locations. It might not succeed (when it returns an empty vector with a warning) and even if it does it might not locate the database used by the date-time code linked into R. Fortunately names are added rarely and most databases are pretty complete. On the other hand, many names which duplicate other named timezones have been moved to the ‘backward’ list – these are regarded as optional and omitted on minimal installations. Similarly, there are timezones named in file ‘backzone’ which differ only from those in the main lists prior to 1970 – these are usually included but may not be in minimalist systems.

For many years, the legacy names `EST5EDT` and `PST8PDT` were portable, but `musl` (the C runtime used by Alpine Linux) does not use DST with those names.

How the system time zone is found – on Unix-alikes

This section is of background interest for users of a Unix-alike, but may help if an NA value is returned unexpectedly.

Commercial Unixen such as Solaris and AIX set `TZ`, so the value when R is started is used.

All other common platforms (Linux, macOS, *BSD) use similar schemes, either derived from `tzcode` (currently distributed from <https://www.iana.org/time-zones>) or independently coded (`glibc`, `musl-libc`). Such systems read the time-zone information from a file ‘localtime’, usually under ‘/etc’ (but possibly under ‘/usr/local/etc’ or ‘/usr/local/etc/zoneinfo’). As the usual Linux manual page for `localtime` says

‘Because the time zone identifier is extracted from the symlink target name of ‘/etc/localtime’, this file may not be a normal file or hardlink.’

Nevertheless, some Linux distributions (including the one from which that quote was taken) or sysadmins have chosen to copy a time-zone file to ‘localtime’. For a non-symlink, the ultimate fallback is to compare that file to all files in the time-zone database.

Some Linux platforms provide two other mechanisms which are tried in turn before looking at ‘/etc/localtime’.

- ‘Modern’ Linux systems use `systemd` which provides mechanisms to set and retrieve the time zone (amongst other things). There is a command `timedatectl` to give details. (Unfortunately RHEL/Centos 6.x were not ‘modern’.)
- Debian-derived systems since *ca* 2007 have supplied a file `‘/etc/timezone’`. Its format is undocumented but empirically it contains a single line of text naming the time zone.

In each case a sanity check is performed that the time-zone name is the name of a file in the time-zone database. (The systems probably use the time-zone file (symlinked to) `‘/etc/localtime’`, but the `Sys.timezone` code does not check that is the same as the named file in the database. This is deliberate as they may be from different dates.)

Note

Since 2007 there has been considerable disruption over changes to the timings of the DST transitions; these often have short notice and time-zone databases may not be up to date. (Morocco in 2013 announced a change to the end of DST at *a day’s* notice. In 2023 there was chaos in Lebanon as the authorities changed their minds repeatedly and some changes were not widely implemented.)

There have also been changes to the ‘standard’ time with little notice (Kazakhstan switched to a single time zone in Mar 2024 with six weeks’ notice), and to whether ‘summer’ or ‘winter’ time is regarded as ‘standard’ (and hence to abbreviations).

On platforms with case-insensitive file systems, time zone names will be case-insensitive. They may or may not be on other platforms and so, for example, `"gmt"` is valid on some platforms and not on others.

Note that except where replaced, the operation of time zones is an OS service, and even where replaced a third-party database is used and can be updated (see the section on ‘Time zone names’). Incorrect results will never be an R issue, so please ensure that you have the courtesy not to blame R for them.

Examples

```
Sys.timezone()

str(OlsonNames()) ## typically around six hundred names,
## typically some acronyms/aliases such as "UTC", "NZ", "MET", "Eire", ..., but
## mostly pairs (and triplets) such as "Pacific/Auckland"
table(sl <- grepl("/", OlsonNames()))
OlsonNames()[!sl] # the simple ones
head(Osl <- strsplit(OlsonNames()[sl], "/"))
(tOsl <- table(vapply(Osl, `[`, "", 1))) # Continents, countries, ...
table(lengths(Osl)) # most are pairs, some triplets
str(Osl[lengths(Osl) >= 3]) # "America" South and North ...
```

toString

Convert an R Object to a Character String

Description

This is a helper function for `format` to produce a single character string describing an R object.

Usage

```
toString(x, ...)  
  
## Default S3 method:  
toString(x, width = NULL, ...)
```

Arguments

<code>x</code>	The object to be converted.
<code>width</code>	Suggestion for the maximum field width. Values of <code>NULL</code> or <code>0</code> indicate no maximum. The minimum value accepted is 6 and smaller values are taken as 6.
<code>...</code>	Optional arguments passed to or from methods.

Details

This is a generic function for which methods can be written: only the default method is described here. Most methods should honor the `width` argument to specify the maximum display width (as measured by `nchar(type = "width")`) of the result.

The default method first converts `x` to character and then concatenates the elements separated by `", "`. If `width` is supplied and is not `NULL`, the default method returns the first `width - 4` characters of the result with `"..."` appended, if the full result would use more than `width` characters.

Value

A character vector of length 1 is returned.

toString(x)  
toString(x, width = 8)
```

trace

*Interactive Tracing and Debugging of Calls to a Function or Method***Description**

A call to `trace` allows you to insert debugging code (e.g., a call to `browser` or `recover`) at chosen places in any function. A call to `untrace` cancels the tracing. Specified methods can be traced the same way, without tracing all calls to the generic function. Trace code (`tracer`) can be any R expression. Tracing can be temporarily turned on or off globally by calling `tracingState`.

Usage

```
trace(what, tracer, exit, at, print, signature,
      where = topenv(parent.frame()), edit = FALSE)
untrace(what, signature = NULL, where = topenv(parent.frame()))

tracingState(on = NULL)
.doTrace(expr, msg)
returnValue(default = NULL)
```

Arguments

what	the name, possibly <code>quote()</code> d, of a function to be traced or untraced. For <code>untrace</code> or for <code>trace</code> with more than one argument, more than one name can be given in the quoted form, and the same action will be applied to each one. For “hidden” functions such as S3 methods in a namespace, <code>where = *</code> typically needs to be specified as well.
tracer	either a <code>function</code> or an unevaluated expression. The function will be called or the expression will be evaluated either at the beginning of the call, or before those steps in the call specified by the argument <code>at</code> . See the details section.
exit	either a <code>function</code> or an unevaluated expression. The function will be called or the expression will be evaluated on exiting the function. See the details section.
at	optional numeric vector or list. If supplied, <code>tracer</code> will be called just before the corresponding step in the body of the function. See the details section.
print	if <code>TRUE</code> (as per default), a descriptive line is printed before any trace expression is evaluated.
signature	an optional signature for a method for function <code>what</code> . If supplied, the method, and <i>not</i> the function itself, is traced.
edit	For complicated tracing, such as tracing within a loop inside the function, you will need to insert the desired calls by editing the body of the function. If so, supply the <code>edit</code> argument either as <code>TRUE</code> , or as the name of the editor you want to use. Then <code>trace()</code> will call <code>edit</code> and use the version of the function after you edit it. See the details section for additional information.
where	where to look for the function to be traced; by default, the top-level environment of the call to <code>trace</code> . An important use of this argument is to trace functions from a package which are “hidden” or called from another package. The namespace mechanism imports the functions to be called (with the exception of functions in the base package). The functions being called are <i>not</i> the same objects seen from the top-level (in

	general, the imported packages may not even be attached). Therefore, you must ensure that the correct versions are being traced. The way to do this is to set argument <code>where</code> to a function in the namespace (or that namespace). The tracing computations will then start looking in the environment of that function (which will be the namespace of the corresponding package). (Yes, it's subtle, but the semantics here are central to how namespaces work in R.)
<code>on</code>	logical; a call to the support function <code>tracingState</code> returns <code>TRUE</code> if tracing is globally turned on, <code>FALSE</code> otherwise. An argument of one or the other of those values sets the state. If the tracing state is <code>FALSE</code>, none of the trace actions will actually occur (used, for example, by debugging functions to shut off tracing during debugging).
<code>expr, msg</code>	arguments to the support function <code>.doTrace</code>, calls to which are inserted into the modified function or method: <code>expr</code> is the tracing action (such as a call to <code>browser()</code>), and <code>msg</code> is a string identifying the place where the trace action occurs.
<code>default</code>	if <code>returnValue</code> finds no return value (e.g., when a function exited because of an error, restart or as a result of evaluating a return from a caller function), it will return <code>default</code> instead.

Details

The `trace` function operates by constructing a revised version of the function (or of the method, if signature is supplied), and assigning the new object back where the original was found. If only the `what` argument is given, a line of trace printing is produced for each call to the function (back compatible with the earlier version of `trace`).

The object constructed by `trace` is from a class that extends "function" and which contains the original, untraced version. A call to `untrace` re-assigns this version.

If the argument `tracer` or `exit` is the name of a function, the tracing expression will be a call to that function, with no arguments. This is the easiest and most common case, with the functions `browser` and `recover` the likeliest candidates; the former browses in the frame of the function being traced, and the latter allows browsing in any of the currently active calls. The arguments `tracer` and `exit` are evaluated to see whether they are functions, but only their names are used in the tracing expressions. The lookup is done again when the traced function executes, so it may not be `tracer` or `exit` that will be called while tracing.

The `tracer` or `exit` argument can also be an unevaluated expression (such as returned by a call to `quote` or `substitute`). This expression itself is inserted in the traced function, so it will typically involve arguments or local objects in the traced function. An expression of this form is useful if you only want to interact when certain conditions apply (and in this case you probably want to supply `print = FALSE` in the call to `trace` also).

When the `at` argument is supplied, it can be a vector of integers referring to the substeps of the body of the function (this only works if the body of the function is enclosed in `{ ... }`). In this case `tracer` is *not* called on entry, but instead just before evaluating each of the steps listed in `at`. (Hint: you don't want to try to count the steps in the printed version of a function; instead, look at `as.list(body(f))` to get the numbers associated with the steps in function `f`.)

The `at` argument can also be a list of integer vectors. In this case, each vector refers to a step nested within another step of the function. For example, `at = list(c(3, 4))` will call the tracer just before the fourth step of the third step of the function. See the example below.

Using `setBreakpoint` (from package `utils`) may be an alternative, calling `trace(..., at, ...)`.

The `exit` argument is called during `on.exit` processing. In an `on.exit` expression, the experimental `returnValue()` function may be called to obtain the value about to be returned by the function. Calling this function in other circumstances will give undefined results.

An intrinsic limitation in the `exit` argument is that it won't work if the function itself uses `on.exit` with `add=FALSE` (the default), since the existing calls will override the one supplied by `trace`.

Tracing does not nest. Any call to `trace` replaces previously traced versions of that function or method (except for edited versions as discussed below), and `untrace` always restores an untraced version. (Allowing nested tracing has too many potentials for confusion and for accidentally leaving traced versions behind.)

When the `edit` argument is used repeatedly with no call to `untrace` on the same function or method in between, the previously edited version is retained. If you want to throw away all the previous tracing and then edit, call `untrace` before the next call to `trace`. Editing may be combined with automatic tracing; just supply the other arguments such as `tracer`, and the `edit` argument as well. The `edit = TRUE` argument uses the default editor (see [edit](#)).

Tracing primitive functions (builtins and specials) from the base package works, but only by a special mechanism and not very informatively. Tracing a primitive causes the primitive to be replaced by a function with argument `...(only)`. You can get a bit of information out, but not much. A warning message is issued when `trace` is used on a primitive.

The practice of saving the traced version of the function back where the function came from means that tracing carries over from one session to another, *if* the traced function is saved in the session image. (In the next session, `untrace` will remove the tracing.) On the other hand, functions that were in a package, not in the global environment, are not saved in the image, so tracing expires with the session for such functions.

Tracing an S4 method is basically just like tracing a function, with the exception that the traced version is stored by a call to `setMethod` rather than by direct assignment, and so is the untraced version after a call to `untrace`.

The version of `trace` described here is largely compatible with the version in S-Plus, although the two work by entirely different mechanisms. The S-Plus `trace` uses the session frame, with the result that tracing never carries over from one session to another (R does not have a session frame). Another relevant distinction has nothing directly to do with `trace`: The browser in S-Plus allows changes to be made to the frame being browsed, and the changes will persist after exiting the browser. The R browser allows changes, but they disappear when the browser exits. This may be relevant in that the S-Plus version allows you to experiment with code changes interactively, but the R version does not. (A future revision may include a 'destructive' browser for R.)

Value

In the simple version (just the first argument), `trace` returns an invisible `NULL`. Otherwise, the traced function(s) name(s). The relevant consequence is the assignment that takes place.

`untrace` returns the function name invisibly.

`tracingState` returns the current global tracing state, and possibly changes it.

When called during `on.exit` processing, `returnValue` returns the value about to be returned by the exiting function. Behaviour in other circumstances is undefined.

Note

Using `trace()` is conceptually a generalization of [debug](#), implemented differently. Namely by calling [browser](#) via its `tracer` or `exit` argument.

The version of function tracing that includes any of the arguments except for the function name requires the **methods** package (because it uses special classes of objects to store and restore versions of the traced functions).

If `methods` dispatch is not currently on, `trace` will load the `methods` namespace, but will not put the `methods` package on the `search` list.

Examples

```
require(stats)

## Very simple use
trace(sum)
hist(rnorm(100)) # shows about 3-4 calls to sum()
untrace(sum)

## Show how pt() is called from inside power.t.test():
if(FALSE)
  trace(pt) ## would show ~20 calls, but we want to see more:
  trace(pt, tracer = quote(cat(sprintf("tracing pt(*, ncp = %.15g)\n", ncp))),
        print = FALSE) # <- not showing typical extra
  power.t.test(20, 1, power=0.8, sd=NULL) ##--> showing the ncp root finding:
  untrace(pt)

f <- function(x, y) {
  y <- pmax(y, 0.001)
  if (x > 0) x ^ y else stop("x must be positive")
}

## arrange to call the browser on entering and exiting
## function f
trace("f", quote(browser(skipCalls = 4)),
      exit = quote(browser(skipCalls = 4)))

## instead, conditionally assign some data, and then browse
## on exit, but only then. Don't bother me otherwise

trace("f", quote(if(any(y < 0)) yOrig <- y),
      exit = quote(if(exists("yOrig")) browser(skipCalls = 4)),
      print = FALSE)

## Enter the browser just before stop() is called. First, find
## the step numbers

untrace(f) # (as it has changed f's body !)
as.list(body(f))
as.list(body(f)[[3]]) # -> stop(..) is [[4]]
```

```
## Now call the browser there

trace("f", quote(browser(skipCalls = 4)), at = list(c(3,4)))
## Not run:
f(-1,2) # --> enters browser just before stop(..)

## End(Not run)

## trace a utility function, with recover so we
## can browse in the calling functions as well.

trace("as.matrix", recover)

## turn off the tracing (that happened above)

untrace(c("f", "as.matrix"))

## Not run:
## Useful to find how system2() is called in a higher-up function:
trace(base::system2, quote(print(ls.str()))))

## End(Not run)

##----- Tracing hidden functions : need 'where = *'
##
## 'where' can be a function whose environment is meant:
trace(quote(ar.yw.default), where = ar)
a <- ar(rnorm(100)) # "Tracing ..."
untrace(quote(ar.yw.default), where = ar)

## trace() more than one function simultaneously:
##      expression(E1, E2, ...) here is equivalent to
##      c(quote(E1), quote(E2), quote(.*), ..)
trace(expression(ar.yw, ar.yw.default), where = ar)
a <- ar(rnorm(100)) # --> 2 x "Tracing ..."
# and turn it off:
untrace(expression(ar.yw, ar.yw.default), where = ar)

## Not run:
## trace calls to the function lm() that come from
## the nlme package.
trace("lm", where = asNamespace("nlme"))
lm      (len ~ log(dose) * supp, ToothGrowth) -> fit1 # NOT traced
nlme::lmList(len ~ log(dose) | supp, ToothGrowth) -> fit2 # traced
untrace("lm", where = asNamespace("nlme"))

## End(Not run)
```

Description

By default `traceback()` prints the call stack of the last uncaught error, i.e., the sequence of calls that lead to the error. This is useful when an error occurs with an unidentifiable error message. It can also be used to print the current stack or arbitrary lists of calls.

`.traceback()` now *returns* the above call stack (and `traceback(x, *)` can be regarded as convenience function for printing the result of `.traceback(x)`).

Usage

```
traceback(x = NULL, max.lines = getOption("traceback.max.lines",
                                           getOption("deparse.max.lines", -1L)))
.traceback(x = NULL, max.lines = getOption("traceback.max.lines",
                                           getOption("deparse.max.lines", -1L)))
```

Arguments

<code>x</code>	NULL (default, meaning <code>.Traceback</code>), or an integer count of calls to skip in the current stack, or a list or pairlist of calls. See the details.
<code>max.lines</code>	a number, the maximum number of lines to be printed <i>per call</i> . The default is unlimited. Applies only when <code>x</code> is NULL, a list or a pairlist of calls, see the details.

Details

The default display is of the stack of the last uncaught error as stored as a list of [calls](#) in `.Traceback`, which `traceback` prints in a user-friendly format. The stack of calls always contains all function calls and all foreign function calls (such as `.Call`): if profiling is in progress it will include calls to some primitive functions. (Calls to builtins are included, but not to specials.)

Errors which are caught *via* [try](#) or [tryCatch](#) do not generate a traceback, so what is printed is the call sequence for the last uncaught error, and not necessarily for the last error.

If `x` is numeric, then the current stack is printed, skipping `x` entries at the top of the stack. For example, `options(error = function() traceback(3))` will print the stack at the time of the error, skipping the call to `traceback()` and `.traceback()` and the error function that called it.

Otherwise, `x` is assumed to be a list or pairlist of calls or deparsed calls and will be displayed in the same way.

`.traceback()` and by extension `traceback()` may trigger deparsing of [calls](#). This is an expensive operation for large calls so it may be advisable to set `max.lines` to a reasonable value when such calls are on the call stack.

Value

`.traceback()` returns the deparsed call stack deepest call first as a list or pairlist. The number of lines deparsed from the call can be limited via `max.lines`. Calls for which `max.lines` results in truncated output will gain a `"truncated"` attribute.

`traceback()` formats, prints, and returns the call stack produced by `.traceback()` invisibly.

Warning

It is undocumented where `.Traceback` is stored nor that it is visible, and this is subject to change. Currently `.Traceback` contains the [calls](#) as language objects.

Examples

```
foo <- function(x) { print(1); bar(2) }
bar <- function(x) { x + a.variable.which.does.not.exist }
## Not run:
foo(2) # gives a strange error
traceback()
## End(Not run)
## 2: bar(2)
## 1: foo(2)
bar
## Ah, this is the culprit ...

## This will print the stack trace at the time of the error.
options(error = function() traceback(3))
```

tracemem

Trace Copying of Objects

Description

This function marks an object so that a message is printed whenever the internal code copies the object. It is a major cause of hard-to-predict memory use in R.

Usage

```
tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)
```

Arguments

<code>x</code>	An R object, not a function or environment or NULL.
<code>previous</code>	A value as returned by <code>tracemem</code> or <code>retracemem</code> .

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. `tracemem` and `untracemem` give errors when R is not compiled with memory profiling; `retracemem` does not (so it can be left in code during development).

It is enabled in the CRAN macOS and Windows builds of R.

When an object is traced any copying of the object by the C function `duplicate` produces a message to standard output, as does type coercion and copying when passing arguments to `.C` or `.Fortran`.

The message consists of the string `tracemem`, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred.

`retracemem()` is used to indicate that a variable should be considered a copy of a previous variable (e.g., after subscripting).

The messages can be turned off with `tracingState`.

It is not possible to trace functions, as this would conflict with `trace` and it is not useful to trace `NULL`, environments, promises, weak references, or external pointer objects, as these are not duplicated.

These functions are `primitive`.

Value

A character string for identifying the object in the trace output (an address in hex enclosed in angle brackets), or `NULL` (invisibly).

See Also

`capabilities("profmem")` to see if this was enabled for this build of R.

`trace`, `Rprofmem`

<https://developer.r-project.org/memory-profiling.html>

Examples

```
## Not run:
a <- 1:10
tracemem(a)
## b and a share memory
b <- a
b[1] <- 1
untracemem(a)

## copying in lm: less than R <= 2.15.0
d <- stats::rnorm(10)
tracemem(d)
lm(d ~ a+log(b))

## f is not a copy and is not traced
f <- d[-1]
f+1
## indicate that f should be traced as a copy of d
retracemem(f, retracemem(d))
f+1

## End(Not run)
```

transform

Transform an Object, for Example a Data Frame

Description

`transform` is a generic function, which—at least currently—only does anything useful with data frames. `transform.default` converts its first argument to a data frame if possible and calls `transform.data.frame`.

Usage

```
transform(`_data`, ...)
```

Arguments

<code>_data</code>	The object to be transformed
<code>...</code>	Further arguments of the form <code>tag=value</code>

Details

The `...` arguments to `transform.data.frame` are tagged vector expressions, which are evaluated in the data frame `_data`. The tags are matched against names (`_data`), and for those that match, the value replace the corresponding variable in `_data`, and the others are appended to `_data`.

Value

The modified value of `_data`.

Warning

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting arithmetic functions, and in particular the non-standard evaluation of argument `transform` can have unanticipated consequences.

Note

If some of the values are not vectors of the appropriate length, you deserve whatever you get!

Author(s)

Peter Dalgaard

See Also

[within](#) for a more flexible approach, [subset](#), [list](#), [data.frame](#)

Examples

```
transform(airquality, Ozone = -Ozone)
transform(airquality, new = -Ozone, Temp = (Temp-32)/1.8)

attach(airquality)
transform(Ozone, logOzone = log(Ozone)) # marginally interesting ...
detach(airquality)
```

Description

These functions give the obvious trigonometric functions. They respectively compute the cosine, sine, tangent, arc-cosine, arc-sine, arc-tangent, and the two-argument arc-tangent.

`cospi(x)`, `sinpi(x)`, and `tanpi(x)`, compute `cos(pi*x)`, `sin(pi*x)`, and `tan(pi*x)`.

Usage

```
cos(x)
sin(x)
tan(x)

acos(x)
asin(x)
atan(x)
atan2(y, x)

cospi(x)
sinpi(x)
tanpi(x)
```

Arguments

`x, y` numeric or complex vectors.

Details

The arc-tangent of two arguments `atan2(y, x)` returns the angle between the x-axis and the vector from the origin to (x, y) , i.e., for positive arguments `atan2(y, x) == atan(y/x)`.

Angles are in radians, not degrees, for the standard versions (i.e., a right angle is $\pi/2$), and in ‘half-rotations’ for `cospi` etc.

`cospi(x)`, `sinpi(x)`, and `tanpi(x)` are accurate for `x` values which are multiples of a half.

All except `atan2` are [internal generic primitive](#) functions: methods can be defined for them individually or via the [Math](#) group generic.

These are all wrappers to system calls of the same name (with prefix `c` for complex arguments) where available. (`cospi`, `sinpi`, and `tanpi` are part of a C11 extension and provided by e.g. macOS and Solaris: where not yet available call to `cos` etc are used, with special cases for multiples of a half.)

Value

`tanpi(0.5)` is [NaN](#). Similarly for other inputs with fractional part 0.5.

Complex values

For the inverse trigonometric functions, branch cuts are defined as in Abramowitz and Stegun (1972, figure 4.4 on page 79).

For `asin` and `acos`, there are two cuts, both along the real axis: $(-\infty, -1]$ and $[1, \infty)$.

For `atan` there are two cuts, both along the pure imaginary axis: $(-\infty i, -1i]$ and $[1i, \infty i)$.

The behaviour actually on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

Complex arguments for `cospi`, `sinpi`, and `tanpi` are not yet implemented, and they are a ‘future direction’ of ISO/IEC TS 18661-4.

S4 methods

All except `atan2` are S4 generic functions: methods can be defined for them individually or via the `Math` group generic.

For `cospi`, `sinpi`, and `tanpi` the C11 extension ISO/IEC TS 18661-4:2015 (draft at <https://www.open-std.org/jtc1/sc22/wg14/www/docs/n1950.pdf>).

Examples

```
x <- seq(-3, 7, by = 1/8)
tx <- cbind(x, cos(pi*x), cospi(x), sin(pi*x), sinpi(x),
            tan(pi*x), tanpi(x), deparse.level=2)
op <- options(digits = 4, width = 90) # for nice formatting
head(tx)
tx[ (x %% 1) %in% c(0, 0.5) ,]
options(op)
```

trimws

Remove Leading/Trailing Whitespace

Description

Remove leading and/or trailing whitespace from character strings.

Usage

```
trimws(x, which = c("both", "left", "right"), whitespace = "[ \\t\\r\\n]")
```

Arguments

<code>x</code>	a character vector.
<code>which</code>	a character string specifying whether to remove both leading and trailing whitespace (default), or only leading (" <code>left</code> ") or trailing (" <code>right</code> "). Can be abbreviated.
<code>whitespace</code>	a string specifying a regular expression to match (one character of) “white space”, see Details for alternatives to the default.

Details

Internally, `sub(re, "", *, perl = TRUE)`, i.e., PCRE library regular expressions are used. For portability, the default ‘whitespace’ is the character class `[\t\r\n]` (space, horizontal tab, carriage return, newline). Alternatively, `[\h\v]` is a good (PCRE) generalization to match all Unicode horizontal and vertical white space characters, see also <https://www.pcre.org>.

Examples

```
x <- "  Some text. "
x
trimws(x)
trimws(x, "l")
trimws(x, "r")

## Unicode --> need "stronger" 'whitespace' to match all :
tt <- "text with unicode 'non breakable space'."
xu <- paste(" \t\v", tt, "\u00a0 \n\r")
(tu <- trimws(xu, whitespace = "[\\h\\v]"))
stopifnot(identical(tu, tt))
```

try

*Try an Expression Allowing Error Recovery***Description**

`try` is a wrapper to run an expression that might fail and allow the user’s code to handle error-recovery.

Usage

```
try(expr, silent = FALSE,
     outFile = getOption("try.outFile", default = stderr()))
```

Arguments

<code>expr</code>	an R expression to try.
<code>silent</code>	logical: should the report of error messages be suppressed?
<code>outFile</code>	a connection , or a character string naming the file to print to (via <code>cat(*, file = outFile)</code>); used only if <code>silent</code> is false, as by default.

Details

`try` evaluates an expression and traps any errors that occur during the evaluation. If an error occurs then the error message is printed to the `stderr` connection unless `options("show.error.messages")` is false or the call includes `silent = TRUE`. The error message is also stored in a buffer where it can be retrieved by `geterrmessage`. (This should not be needed as the value returned in case of an error contains the error message.)

`try` is implemented using `tryCatch`; for programming, instead of `try(expr, silent = TRUE)`, something like `tryCatch(expr, error = function(e) e)` (or other simple error handler functions) may be more efficient and flexible.

It may be useful to set the default for `outFile` to `stdout()`, i.e.,

```
options(try.outFile = stdout())
```

instead of the default `stderr()`, notably when `try()` is used inside a `Sweave` code chunk and the error message should appear in the resulting document.

Value

The value of the expression if `expr` is evaluated without error; otherwise an invisible object inheriting from class `"try-error"` containing the error message with the error condition as the `"condition"` attribute.

Warning

Do not test

```
if (class(res) == "try-error")
```

as if there is no error, the result might (now or in future) have a class of length > 1. Use `if(inherits(res, "try-error"))` instead.

See Also

`options` for setting error handlers and suppressing the printing of error messages; `geterrmessage` for retrieving the last error message. The underlying `tryCatch` provides more flexible means of catching and handling errors.

`assertCondition` in package `tools` is related and useful for testing.

Examples

```
## this example will not work correctly in example(try), but
## it does work correctly if pasted in
options(show.error.messages = FALSE)
try(log("a"))
print(.Last.value)
options(show.error.messages = TRUE)

## alternatively,
print(try(log("a"), TRUE))

## run a simulation, keep only the results that worked.
set.seed(123)
x <- stats::rnorm(50)
```

```

doit <- function(x)
{
  x <- sample(x, replace = TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
## alternative 1
res <- lapply(1:100, function(i) try(doit(x), TRUE))
## alternative 2
## Not run: res <- vector("list", 100)
for(i in 1:100) res[[i]] <- try(doit(x), TRUE)
## End(Not run)
unlist(res[sapply(res, function(x) !inherits(x, "try-error"))])

```

typeof

*The Type of an Object***Description**

typeof determines the (R internal) type or storage mode of any object

Usage

```
typeof(x)
```

Arguments

x any R object.

Value

A character string. The possible values are listed in the structure `TypeTable` in `'src/main/util.c'`. Current values are the vector types "logical", "integer", "double", "complex", "character", "raw" and "list", "NULL", "closure" (function), "special" and "builtin" (basic functions and operators), "environment", "S4" (some S4 objects) and others that are unlikely to be seen at user level ("symbol", "pairlist", "promise", "object", "language", "char", "...", "any", "expression", "externalptr", "bytecode" and "weakref").

See Also

[mode](#), [storage.mode](#).

[isS4](#) to determine if an object has an S4 class.

Examples

```

typeof(2)
mode(2)
## for a table of examples, see ?mode / examples(mode)

```

unique

*Extract Unique Elements***Description**

`unique` returns a vector, data frame or array like `x` but with duplicate elements/rows removed.

Usage

```
unique(x, incomparables = FALSE, ...)

## Default S3 method:
unique(x, incomparables = FALSE, fromLast = FALSE,
       nmax = NA, ...)

## S3 method for class 'matrix'
unique(x, incomparables = FALSE, MARGIN = 1,
       fromLast = FALSE, ...)

## S3 method for class 'array'
unique(x, incomparables = FALSE, MARGIN = 1,
       fromLast = FALSE, ...)
```

Arguments

<code>x</code>	a (generalized, see is.vector) vector, a data frame, an array or <code>NULL</code> .
<code>incomparables</code>	a vector of values that cannot be compared. <code>FALSE</code> is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as <code>x</code> .
<code>fromLast</code>	logical indicating if duplication should be considered from the last, i.e., the last (or rightmost) of identical elements will be kept. This only matters for names or dimnames .
<code>nmax</code>	the maximum number of unique items expected (greater than one). See duplicated .
<code>...</code>	arguments for particular methods.
<code>MARGIN</code>	the array margin to be held fixed: a single integer.

Details

This is a generic function with methods for generalized (in the sense of [is.vector](#)) vectors, data frames and arrays (including matrices).

The array method calculates for each element of the dimension specified by `MARGIN` if the remaining dimensions are identical to those for an earlier element (in row-major order). This would most commonly be used for matrices to find unique rows (the default) or columns (with `MARGIN = 2`).

Note that unlike the Unix command `uniq` this omits *duplicated* and not just *repeated* elements/rows. That is, an element is omitted if it is equal to any previous element and not just if it is equal the immediately previous one. (For the latter, see [rle](#)).

Missing values ("[NA](#)") are regarded as equal, numeric and complex ones differing from `NaN`; character strings will be compared in a “common encoding”; for details, see [match](#) (and [duplicated](#)) which use the same concept.

Values in `incomparables` will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

When used on a data frame with more than one column, or an array or matrix when comparing dimensions of length greater than one, this tests for identity of character representations. This will catch people who unwisely rely on exact equality of floating-point numbers!

Value

For a vector, an object of the same type of `x`, but with only one copy of each duplicated element. No attributes are copied (so the result has no names). The default method also keeps (number-like) date-time vectors of classes "[POSIXct](#)", "[Date](#)", and "[difftime](#)".

For a data frame, a data frame is returned with the same columns but possibly fewer rows (and with row names from the first occurrences of the unique rows).

A matrix or array is subsetted by `[, drop = FALSE]`, so dimensions and dimnames are copied appropriately, and the result always has the same number of dimensions as `x`.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see [vector](#)) or differ only in their attributes. In the worst case it is $O(n^2)$.

See Also

[duplicated](#) which gives the indices of duplicated elements.

[rle](#) which is the equivalent of the Unix `uniq -c` command.

Examples

```
x <- c(3:5, 11:8, 8 + 0:5)
(ux <- unique(x))
(u2 <- unique(x, fromLast = TRUE)) # different order
stopifnot(identical(sort(ux), sort(u2)))

length(unique(sample(100, 100, replace = TRUE)))
## approximately 100(1 - 1/e) = 63.21

unique(iris)
```

units	<i>Units</i>
-------	--------------

Description

Get or set units.

Usage

```
units(x)
units(x) <- value
```

Arguments

x	an R object
value	an R object

Details

These are generic functions, with methods for "[difftime](#)" objects.

unlink	<i>Delete Files and Directories</i>
--------	-------------------------------------

Description

unlink deletes the file(s) or directories specified by x.

Usage

```
unlink(x, recursive = FALSE, force = FALSE, expand = TRUE)
```

Arguments

x	a character vector with the names of the file(s) or directories to be deleted.
recursive	logical. Should directories be deleted recursively?
force	logical. Should permissions be changed (if possible) to allow the file or directory to be removed?
expand	logical. Should wildcards (see ‘Details’ below) and tilde (see path.expand) be expanded?

Details

If `recursive = FALSE` directories are not deleted, not even empty ones.

On most platforms ‘file’ includes symbolic links, fifos and sockets. `unlink(x, recursive = TRUE)` deletes just the symbolic link if the target of such a link is a directory.

Wildcard expansion (normally ‘*’ and ‘?’ are allowed) is done by the internal code of `Sys.glob`. Wildcards never match a leading ‘.’ in the filename, and files ‘.’, ‘..’ and ‘~’ will never be considered for deletion. Wildcards will only be expanded if the system supports it. Most systems will support not only ‘*’ and ‘?’ but also character classes such as ‘[a-z]’ (see the man pages for the system call `glob` on your OS). The metacharacters * ? [can occur in Unix filenames, and this makes it difficult to use `unlink` to delete such files (see `file.remove`), although escaping the metacharacters by backslashes usually works. If a metacharacter matches nothing it is considered as a literal character.

`recursive = TRUE` might not be supported on all platforms, when it will be ignored, with a warning: however there are no known current examples.

Value

0 for success, 1 for failure, invisibly. Not deleting a non-existent file is not a failure, nor is being unable to delete a directory if `recursive = FALSE`. However, missing values in `x` are regarded as failures.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`file.remove`.

unlist	<i>Flatten Lists</i>
--------	----------------------

Description

Given a list structure `x`, `unlist` simplifies it to produce a vector which contains all the atomic components which occur in `x`.

Usage

```
unlist(x, recursive = TRUE, use.names = TRUE)
```

Arguments

<code>x</code>	an R object, typically a list or vector.
<code>recursive</code>	logical (TRUE or FALSE). Should unlisting be applied to list components of <code>x</code> ?
<code>use.names</code>	logical. Should names be preserved?

Details

`unlist` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#), and note, e.g., `relist` with the `unlist` method for `relistable` objects.

If `recursive = FALSE`, the function will not recurse beyond the first level items in `x`.

Factors are treated specially. If all non-list elements of `x` are `factor` (or ordered factor) objects then the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result).

`x` can be an atomic vector, but then `unlist` does nothing useful, not even drop names.

By default, `unlist` tries to retain the naming information present in `x`. If `use.names = FALSE` all naming information is dropped.

Where possible the list elements are coerced to a common mode during the unlisting, and so the result often ends up as a character vector. Vectors will be coerced to the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`: pairlists are treated as lists.

A list is a (generic) vector, and the simplified vector might still be a list (and might be unchanged). Non-vector elements of the list (for example language elements such as names, formulas and calls) are not coerced, and so a list containing one or more of these remains a list. (The effect of unlisting an `lm` fit is a list which has individual residuals as components.) Note that `unlist(x)` now returns `x` unchanged also for non-vector `x`, instead of signalling an error in that case.

Value

`NULL` or an expression or a vector of an appropriate mode to hold the list components.

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`, after coercion of pairlists to lists.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`c`, `as.list`, `relist`.

Examples

```
unlist(options())
unlist(options(), use.names = FALSE)

l.ex <- list(a = list(1:5, LETTERS[1:5]), b = "Z", c = NA)
unlist(l.ex, recursive = FALSE)
unlist(l.ex, recursive = TRUE)

l1 <- list(a = "a", b = 2, c = pi+2i)
unlist(l1) # a character vector
l2 <- list(a = "a", b = as.name("b"), c = pi+2i)
unlist(l2) # remains a list

l1 <- list(as.name("sinc"), quote( a + b ), 1:10, letters, expression(1+x))
```

```
utils::str(l1)
for(x in l1)
  stopifnot(identical(x, unlist(x)))
```

unname	<i>Remove names or dimnames</i>
--------	---------------------------------

Description

Remove the `names` or `dimnames` attribute of an R object.

Usage

```
unname(obj, force = FALSE)
```

Arguments

<code>obj</code>	an R object.
<code>force</code>	logical; if true, the <code>dimnames</code> (names and row names) are removed even from <code>data.frames</code> .

Value

Object as `obj` but without `names` or `dimnames`.

Examples

```
require(graphics); require(stats)

## Answering a question on R-help (14 Oct 1999):
col3 <- 750+ 100*rt(1500, df = 3)
breaks <- factor(cut(col3, breaks = 360+5*(0:155)))
z <- table(breaks)
z[1:5] # The names are larger than the data ...
barplot(unname(z), axes = FALSE)
```

use	<i>Use Packages</i>
-----	---------------------

Description

Use packages in R scripts by loading their namespace and attaching a package environment including (a subset of) their exports to the search path.

Usage

```
use(package, include.only)
```

Arguments

`package` a character string given the name of a package.

`include.only` character vector of names of objects to include in the attached environment frame. If missing, all exports are included.

Details

This is a simple wrapper around `library` which always uses `attach.required = FALSE`, so that packages listed in the `Depends` clause of the `DESCRIPTION` file of the package to be used never get attached automatically to the search path.

This therefore allows to write R scripts with full control over what gets found on the search path. In addition, such scripts can easily be integrated as package code, replacing the calls to `use` by the corresponding `ImportFrom` directives in ‘NAMESPACE’ files.

Value

(invisibly) a logical indicating whether the package to be used is available.

Note

This functionality is still experimental: interfaces may change in future versions.

UseMethod	<i>Class Methods</i>
-----------	----------------------

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class(es) of the first argument to the generic function or of the object supplied as an argument to `UseMethod` or `NextMethod`.

Usage

```
UseMethod(generic, object)

NextMethod(generic = NULL, object = NULL, ...)
```

Arguments

`generic` a character string naming a function (and not a built-in operator). Required for `UseMethod`.

`object` for `UseMethod`: an object whose class will determine the method to be dispatched. Defaults to the first argument of the enclosing function.

`...` further arguments to be passed to the next method.

Details

An R object is a data object which has a `class` attribute (and this can be tested by `is.object`). A class attribute is a character vector giving the names of the classes from which the object *inherits*.

If the object does not have a class attribute, it has an *implicit class*. Matrices and arrays have class `"matrix"` or `"array"` followed by the class of the underlying vector. Most vectors have class the result of `mode(x)`, except that integer vectors have class `c("integer", "numeric")` and real vectors have class `c("double", "numeric")`. Function `.class2(x)` (since R 4.0.x) returns the full implicit (or explicit) class vector of `x`.

When a function calling `UseMethod("fun")` is applied to an object with class vector `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used, if it exists, or an error results.

Function `methods` can be used to find out about the methods for a particular generic function or class.

`UseMethod` is a primitive function but uses standard argument matching. It is not the only means of dispatch of methods, for there are [internal generic](#) and [group generic](#) functions. `UseMethod` currently dispatches on the implicit class even for arguments that are not objects, but the other means of dispatch do not.

`NextMethod` invokes the next method (determined by the class vector, either of the object supplied to the generic, or of the first argument to the function containing `NextMethod` if a method was invoked directly). Normally `NextMethod` is used with only one argument, `generic`, but if further arguments are supplied these modify the call to the next method.

`NextMethod` should not be called except in methods called by `UseMethod` or from internal generics (see [InternalGenerics](#)). In particular it will not work inside anonymous calling functions (e.g., `get("print.ts")` (`AirPassengers`)).

Namespaces can register methods for generic functions. To support this, `UseMethod` and `NextMethod` search for methods in two places: in the environment in which the generic function is called, and in the registration data base for the environment in which the generic is defined (typically a namespace). So methods for a generic function need to be available in the environment of the call to the generic, or they must be registered. (It does not matter whether they are visible in the environment in which the generic is defined.) As from R 3.5.0, the registration data base is searched after the top level environment (see [topenv](#)) of the calling environment (but before the parents of the top level environment).

Technical Details

Now for some obscure details that need to appear somewhere. These comments will be slightly different than those in Chambers (1992). (See also the draft of [The R Language Definition](#).) `UseMethod` creates a new function call with arguments matched as they came in to the generic. [Previously local variables defined before the call to `UseMethod` were retained; as of R 4.4.0 this is no longer the case.] Any statements after the call to `UseMethod` will not be evaluated as `UseMethod` does not return. `UseMethod` can be called with more than two arguments: a warning will be given and additional arguments ignored. (They are not completely ignored in S.) If it is called with just one argument, the class of the first argument of the enclosing function is used as `object`: unlike S this is the first actual argument passed and not the current value of the object of that name.

`NextMethod` works by creating a special call frame for the next method. If no new arguments are supplied, the arguments will be the same in number, order and name as those to the current method but their values will be promises to evaluate their name in the current method and environment.

Any arguments matched to `...` are handled specially: named arguments either replace existing arguments of the same name or are appended to the argument list, unnamed arguments are appended to the argument list. They are passed on as the promise that was supplied as an argument to the current environment. (S does this differently!) If they have been evaluated in the current (or a previous environment) they remain evaluated. (This is a complex area, and subject to change: see the draft of *The R Language Definition*.)

The search for methods for `NextMethod` is slightly different from that for `UseMethod`. Finding no `fun.default` is not necessarily an error, as the search continues to the generic itself. This is to pick up an *internal generic* like `[]` which has no separate default method, and succeeds only if the generic is a *primitive* function or a wrapper for a `.Internal` function of the same name. (When a primitive is called as the default method, argument matching may not work as described above due to the different semantics of primitives.)

You will see objects such as `.Generic`, `.Method`, and `.Class` used in methods. These are set in the environment within which the method is evaluated by the dispatch mechanism, which is as follows:

1. Find the context for the calling function (the generic): this gives us the unevaluated arguments for the original call.
2. Evaluate the object (usually an argument) to be used for dispatch, and find a method (possibly the default method) or throw an error.
3. Create an environment for evaluating the method and insert special variables (see below) into that environment. Also copy any variables in the environment of the generic that are not formal (or actual) arguments.
4. Fix up the argument list to be the arguments of the call matched to the formals of the method.

`.Generic` is a length-one character vector naming the generic function.

`.Method` is a character vector (normally of length one) naming the method function. (For functions in the group generic *Ops* it is of length two.)

`.Class` is a character vector of classes used to find the next method. `NextMethod` adds an attribute "previous" to `.Class` giving the `.Class` last used for dispatch, and shifts `.Class` along to that used for dispatch.

`.GenericCallEnv` and `.GenericDefEnv` are the environments of the call to be generic and defining the generic respectively. (The latter is used to find methods registered for the generic.)

Note that `.Class` is set when the generic is called, and is unchanged if the class of the dispatching argument is changed in a method. It is possible to change the method that `NextMethod` would dispatch by manipulating `.Class`, but ‘this is not recommended unless you understand the inheritance mechanism thoroughly’ (Chambers 1992, page 469).

Note

This scheme is called *S3* (S version 3). For new projects, it is recommended to use the more flexible and robust *S4* scheme provided in the **methods** package.

userhooks

Functions to Get and Set Hooks for Load, Attach, Detach and Unload

Description

These functions allow users to set actions to be taken before packages are attached/detached and namespaces are (un)loaded.

Usage

```
getHook(hookName)
setHook(hookName, value,
        action = c("append", "prepend", "replace"))

packageEvent(pkgname,
             event = c("onLoad", "attach", "detach", "onUnload"))
```

Arguments

<code>hookName</code>	character string: the hook name.
<code>pkgname</code>	character string: the package/namespace name.
<code>event</code>	character string: an event for the package. Can be abbreviated.
<code>value</code>	a function or a list of functions, or for <code>action = "replace"</code> , <code>NULL</code> .
<code>action</code>	the action to be taken. Can be abbreviated.

Details

`setHook` provides a general mechanism for users to register hooks, a list of functions to be called from system (or user) functions. The initial set of hooks was associated with events on packages/namespaces: these hooks are named via calls to `packageEvent`.

To remove a hook completely, call `setHook(hookName, NULL, "replace")`.

When an R package is attached by `library` or loaded by other means, it can call initialization code. See `.onLoad` for a description of the package hook functions called during initialization. Users can add their own initialization code via the hooks provided by `setHook()`, functions which will be called as `funname(pkgname, pkgpath)` inside a `try` call.

The sequence of events depends on which hooks are defined, and whether a package is attached or just loaded. In the case where all hooks are defined and a package is attached, the order of initialization events is as follows:

1. The package namespace is loaded.
2. The package's `.onLoad` function is run.
3. If S4 methods dispatch is on, any actions set by `setLoadAction` are run.
4. The namespace is sealed.

5. The user's "onLoad" hook is run.
6. The package is added to the search path.
7. The package's `.onAttach` function is run.
8. The package environment is sealed.
9. The user's "attach" hook is run.

A similar sequence (but in reverse) is run when a package is detached and its namespace unloaded:

1. The user's "detach" hook is run.
2. The package's `.Last.lib` function is run.
3. The package is removed from the search path.
4. The user's "onUnload" hook is run.
5. The package's `.onUnload` function is run.
6. The package namespace is unloaded.

Note that when an R session is finished, packages are not detached and namespaces are not unloaded, so the corresponding hooks will not be run.

Also note that some of the user hooks are run without the package being on the search path, so in those hooks objects in the package need to be referred to using the double (or triple) colon operator, as in the example.

If multiple hooks are added, they are normally run in the order shown by `getHook`, but the "detach" and "onUnload" hooks are run in reverse order so the default for package events is to add hooks 'inside' existing ones.

The hooks are stored in the environment `.userHooksEnv` in the base package, with 'mangled' names.

Value

For `getHook` function, a list of functions (possibly empty). For `setHook` function, no return value. For `packageEvent`, the derived hook name (a character string).

Note

Hooks need to be set before the event they modify: for standard packages this can be problematic as **methods** is loaded and attached early in the startup sequence. The usual place to set hooks such as the example below is in the `‘.Rprofile’` file, but that will not work for **methods**.

See Also

`library`, `detach`, `loadNamespace`.

See `::` for a discussion of the double and triple colon operators.

Other hooks may be added later: functions `plot.new` and `persp` already have them.

Examples

```
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::ps.options(horizontal = FALSE))
```

utf8Conversion

*Convert Integer Vectors to or from UTF-8-encoded Character Vectors***Description**

Conversion of UTF-8 encoded character vectors to and from integer vectors representing a UTF-32 encoding.

Usage

```
utf8ToInt(x)
intToUtf8(x, multiple = FALSE, allow_surrogate_pairs = FALSE)
```

Arguments

<code>x</code>	object to be converted.
<code>multiple</code>	logical: should the conversion be to a single character string or multiple individual characters?
<code>allow_surrogate_pairs</code>	logical: should interpretation of surrogate pairs be attempted? (See ‘Details’.) Only supported for <code>multiple = FALSE</code> .

Details

These will work in any locale, including on platforms that do not otherwise support multi-byte character sets.

Unicode defines a name and a number of all of the glyphs it encompasses: the numbers are called *code points*: since RFC3629 they run from 0 to 0x10FFFF (with about 5% being assigned by version 13.0 of the Unicode standard and 7% reserved for ‘private use’).

`intToUtf8` does not by default handle surrogate pairs: inputs in the surrogate ranges are mapped to NA. They might occur if a UTF-16 byte stream has been read as 2-byte integers (in the correct byte order), in which case `allow_surrogate_pairs = TRUE` will try to interpret them (with unmatched surrogate values still treated as NA).

Value

`utf8ToInt` converts a length-one character string encoded in UTF-8 to an integer vector of Unicode code points.

`intToUtf8` converts a numeric vector of Unicode code points either (default) to a single character string or a character vector of single characters. Non-integral numeric values are truncated to integers. For output to a single character string 0 is silently omitted: otherwise 0 is mapped to "". The [Encoding](#) of a non-NA return value is declared as "UTF-8".

Invalid and NA inputs are mapped to NA output.

Validity

Which code points are regarded as valid has changed over the lifetime of UTF-8. Originally all 32-bit unsigned integers were potentially valid and could be converted to up to 6 bytes in UTF-8. Since 2003 it has been stated that there will never be valid code points larger than 0x10FFFF, and so valid UTF-8 encodings are never more than 4 bytes.

The code points in the surrogate-pair range 0xD800 to 0xDFFF are prohibited in UTF-8 and so are regarded as invalid by `utf8ToInt` and by default by `intToUtf8`.

The position of ‘noncharacters’ (notably 0xFFFE and 0xFFFF) was clarified by ‘Corrigendum 9’ in 2013. These are valid but will never be given an official interpretation. (In some earlier versions of `R utf8ToInt` treated them as invalid.)

References

<https://www.rfc-editor.org/rfc/rfc3629>, the current standard for UTF-8.
<https://www.unicode.org/versions/corrigendum9.html> for non-characters.

Examples

```
## will only display in some locales and fonts
intToUtf8(0x03B2L) # Greek beta

utf8ToInt("bi\u00dfchen")
utf8ToInt("\xfa\xfb\xfc\xfd\xfe")

## A valid UTF-16 surrogate pair (for U+10437)
x <- c(0xD801, 0xDC37)
intToUtf8(x)
intToUtf8(x, TRUE)
(xx <- intToUtf8(x, , TRUE)) # will only display in some locales and fonts
charToRaw(xx)

## An example of how surrogate pairs might occur
x <- "\U10437"
charToRaw(x)
foo <- tempfile()
writeLines(x, file(foo, encoding = "UTF-16LE"))
## next two are OS-specific, but are mandated by POSIX
system(paste("od -x", foo)) # 2-byte units, correct on little-endian platforms
system(paste("od -t x1", foo)) # single bytes as hex
y <- readBin(foo, "integer", 2, 2, FALSE, endian = "little")
sprintf("%X", y)
intToUtf8(y, , TRUE)
```

UTF8filepaths

File Paths not in the Native Encoding

Description

Most modern file systems store file-path components (names of directories and files) in a character encoding of wide scope: usually UTF-8 on a Unix-alike and UCS-2/UTF-16 on Windows. However, this was not true when `R` was first developed and there are still exceptions amongst file systems, e.g. FAT32.

This was not something anticipated by the C and POSIX standards which only provide means to access files *via* file paths encoded in the current locale, for example those specified in Latin-1 in a Latin-1 locale.

Everything here apart from the specific section on Windows is about Unix-alikes.

Details

It is possible to mark character strings (elements of character vectors) as being in UTF-8 or Latin-1 (see [Encoding](#)). This allows file paths not in the native encoding to be expressed in R character vectors but there is almost no way to use them unless they can be translated to the native encoding. That is of course not a problem if that is UTF-8, so these details are really only relevant to the use of a non-UTF-8 locale (including a C locale) on a Unix-alike.

Functions to open a file such as `file`, `fifo`, `pipe`, `gzfile`, `bzfile`, `xzfile` and `unz` give an error for non-native filepaths. Where functions look at existence such as `file.exists`, `dir.exists`, `unlink`, `file.info` and `list.files`, non-native filepaths are treated as non-existent.

Many other functions use `file` or `gzfile` to open their files.

`file.path` allows non-native file paths to be combined, marking them as UTF-8 if needed.

`path.expand` only handles paths in the native encoding.

Windows

Windows provides proprietary entry points to access its file systems, and these gained ‘wide’ versions in Windows NT that allowed file paths in UCS-2/UTF-16 to be accessed from any locale.

Some R functions use these entry points when file paths are marked as Latin-1 or UTF-8 to allow access to paths not in the current encoding. These include `file`, `file.access`, `file.append`, `file.copy`, `file.create`, `file.exists`, `file.info`, `file.link`, `file.remove`, `file.rename`, `file.symlink` and `dir.create`, `dir.exists`, `normalizePath`, `path.expand`, `pipe`, `Sys.glob`, `Sys.junction`, `unlink` but not `gzfile`, `bzfile`, `xzfile` nor `unz`.

For functions using `gzfile` (including `load`, `readRDS`, `read.dcf` and `tar`), it is often possible to use a `gzcon` connection wrapping a `file` connection.

Other notable exceptions are `list.files`, `list.dirs`, `system` and file-path inputs for graphics devices.

Historical comment

Before R 4.0.0, file paths marked as being in Latin-1 or UTF-8 were silently translated to the native encoding using escapes such as ‘<e7>’ or ‘<U+00e7>’. This created valid file names but maybe not those intended.

Note

This document is still a work-in-progress.

validUTF8

Check if a Character Vector is Validly Encoded

Description

Check if each element of a character vector is valid in its implied encoding.

Usage

```
validUTF8(x)
validEnc(x)
```

Arguments

`x` a character vector.

Details

These use similar checks to those used by functions such as [grep](#).

`validUTF8` ignores any marked encoding (see [Encoding](#)) and so looks directly if the bytes in each string are valid UTF-8. (For the validity of ‘noncharacters’ see the help for [intToUtf8](#).)

`validEnc` regards character strings as validly encoded unless their encodings are marked as UTF-8 or they are unmarked and the R session is in a UTF-8 or other multi-byte locale. (The checks in other multi-byte locales depend on the OS and as with [iconv](#) not all invalid inputs may be detected.)

Value

A logical vector of the same length as `x`. NA elements are regarded as validly encoded.

Note

It would be possible to check for the validity of character strings in a Latin-1 encoding, but extensions such as CP1252 are widely accepted as ‘Latin-1’ and 8-bit encodings rarely need to be checked for validity.

Examples

```
x <-
  ## from example(text)
  c("Jetzt", "no", "chli", "z\xc3\xbcrit\xc3\xbc\xc3\xbctsch:",
    "(noch", "ein", "bi\xc3\x9fchen", "Z\xc3\xbc", "deutsch)",
    ## from a CRAN check log
    "\xfa\xbf\xbf\x9f")
validUTF8(x)
validEnc(x) # depends on the locale
Encoding(x) <-"UTF-8"
validEnc(x) # typically the last, x[10], is invalid

## Maybe advantageous to declare it "unknown":
G <- x ; Encoding(G[!validEnc(G)]) <- "unknown"
try( substr(x, 1,1) ) # gives 'invalid multibyte string' error in a UTF-8 locale
try( substr(G, 1,1) ) # works in a UTF-8 locale
nchar(G) # fine, too
## but it is not "more valid" typically:
all.equal(validEnc(x),
          validEnc(G)) # typically TRUE
```

Description

A *vector* in R is either an atomic vector i.e., one of the atomic types, see ‘Details’, or of type `(typeof)` or mode `list` or `expression`.

`vector` produces a ‘simple’ vector of the given length and mode, where a ‘simple’ vector has no attribute, i.e., fulfills `is.null(attributes(.))`.

`as.vector`, a generic, attempts to coerce its argument into a vector of mode `mode` (the default is to coerce to whichever vector mode is most convenient): if the result is atomic (`is.atomic`), all attributes are removed. For `mode="any"`, see ‘Details’.

`is.vector(x)` returns TRUE if `x` is a vector of the specified mode having no attributes *other than names*. For `mode="any"`, see ‘Details’.

Usage

```
vector(mode = "logical", length = 0)
as.vector(x, mode = "any")
is.vector(x, mode = "any")
```

Arguments

<code>mode</code>	character string naming an atomic mode or "list" or "expression" or (except for <code>vector</code>) "any". Currently, <code>is.vector()</code> allows any type (see <code>typeof</code>) for mode, and when mode is not "any", <code>is.vector(x, mode)</code> is almost the same as <code>typeof(x) == mode</code> .
<code>length</code>	a non-negative integer specifying the desired length. For a long vector , i.e., <code>length > .Machine\$integer.max</code> , it has to be of type "double". Supplying an argument of length other than one is an error.
<code>x</code>	an R object.

Details

The atomic modes are "logical", "integer", "numeric" (synonym "double"), "complex", "character" and "raw".

If `mode="any"`, `is.vector` may return TRUE for the atomic modes, `list` and `expression`. For any mode, it will return FALSE if `x` has any attributes except names. (This is incompatible with S.) On the other hand, `as.vector` removes *all* attributes including names for results of atomic mode.

For `mode="any"`, and atomic vectors `x`, `as.vector(x)` strips all `attributes` (including `names`), returning a simple atomic vector.

However, when `x` is of type "list" or "expression", `as.vector(x)` currently returns the argument `x` unchanged, unless there is an `as.vector` method for `class(x)`.

Note that factors are *not* vectors; `is.vector` returns FALSE and `as.vector` converts a factor to a character vector for `mode="any"`.

Value

For `vector`, a vector of the given length and mode. Logical vector elements are initialized to FALSE, numeric vector elements to 0, character vector elements to "", raw vector elements to nul bytes and list/expression elements to NULL.

For `as.vector`, a vector (atomic or of type list or expression). All attributes are removed from the result if it is of an atomic mode, but not in general for a list or expression result. The default method

handles 24 input types and 12 values of type: the details of most coercions are undocumented and subject to change.

For `is.vector`, TRUE or FALSE. `is.vector(x, mode = "numeric")` can be true for vectors of types "integer" or "double" whereas `is.vector(x, mode = "double")` can only be true for those of type "double".

Methods for `as.vector()`

Writers of methods for `as.vector` need to take care to follow the conventions of the default method. In particular

- Argument `mode` can be "any", any of the atomic modes, "list", "expression", "symbol", "pairlist" or one of the aliases "double" and "name".
- The return value should be of the appropriate mode. For `mode = "any"` this means an atomic vector or list or expression.
- Attributes should be treated appropriately: in particular when the result is an atomic vector there should be no attributes, not even names.
- `is.vector(as.vector(x, m), m)` should be true for any mode `m`, including the default "any".

Currently this is not fulfilled in R when `m == "any"` and `x` is of type `list` or `expression` with attributes in addition to `names` — typically the case for (S3 or S4) objects (see `is.object`) which are lists internally.

Note

`as.vector` and `is.vector` are quite distinct from the meaning of the formal class "vector" in the **methods** package, and hence `as(x, "vector")` and `is(x, "vector")`.

Note that `as.vector(x)` is not necessarily a null operation if `is.vector(x)` is true: any names will be removed from an atomic vector.

Non-vector modes "symbol" (synonym "name") and "pairlist" are accepted but have long been undocumented: they are used to implement `as.name` and `as.pairlist`, and those functions should preferably be used directly. None of the description here applies to those modes: see the help for the preferred forms.

Examples

```
df <- data.frame(x = 1:3, y = 5:7)
## Error:
try(as.vector(data.frame(x = 1:3, y = 5:7), mode = "numeric"))

x <- c(a = 1, b = 2)
is.vector(x)
as.vector(x)
all.equal(x, as.vector(x)) ## FALSE
```

```
###-- All the following are TRUE:
is.list(df)
! is.vector(df)
! is.vector(df, mode = "list")

is.vector(list(), mode = "list")
```

Vectorize

Vectorize a Scalar Function

Description

Vectorize creates a function wrapper that vectorizes the action of its argument FUN.

Usage

```
Vectorize(FUN, vectorize.args = arg.names, SIMPLIFY = TRUE,
          USE.NAMES = TRUE)
```

Arguments

FUN	function to apply, found via match.fun .
vectorize.args	a character vector of arguments which should be vectorized. Defaults to all arguments of FUN.
SIMPLIFY	logical or character string; attempt to reduce the result to a vector, matrix or higher dimensional array; see the simplify argument of sapply .
USE.NAMES	logical; use names if the first ... argument has names, or if it is a character vector, use that character vector as the names.

Details

The arguments named in the `vectorize.args` argument to `Vectorize` are the arguments passed in the ... list to [mapply](#). Only those that are actually passed will be vectorized; default values will not. See the examples.

`Vectorize` cannot be used with primitive functions as they do not have a value for [formals](#).

It also cannot be used with functions that have arguments named `FUN`, `vectorize.args`, `SIMPLIFY` or `USE.NAMES`, as they will interfere with the `Vectorize` arguments. See the `combn` example below for a workaround.

Value

A function with the same arguments as `FUN`, wrapping a call to [mapply](#).

Examples

```
# We use rep.int as rep is primitive
vrep <- Vectorize(rep.int)
vrep(1:4, 4:1)
vrep(times = 1:4, x = 4:1)

vrep <- Vectorize(rep.int, "times")
vrep(times = 1:4, x = 42)

f <- function(x = 1:3, y) c(x, y)
vf <- Vectorize(f, SIMPLIFY = FALSE)
f(1:3, 1:3)
vf(1:3, 1:3)
vf(y = 1:3) # Only vectorizes y, not x

# Nonlinear regression contour plot, based on nls() example
require(graphics)
SS <- function(Vm, K, resp, conc) {
  pred <- (Vm * conc)/(K + conc)
  sum((resp - pred)^2 / pred)
}
vSS <- Vectorize(SS, c("Vm", "K"))
Treated <- subset(Puromycin, state == "treated")

Vm <- seq(140, 310, length.out = 50)
K <- seq(0, 0.15, length.out = 40)
SSvals <- outer(Vm, K, vSS, Treated$rate, Treated$conc)
contour(Vm, K, SSvals, levels = (1:10)^2, xlab = "Vm", ylab = "K")

# combn() has an argument named FUN
combnV <- Vectorize(function(x, m, FUNV = NULL) combn(x, m, FUN = FUNV),
  vectorize.args = c("x", "m"))
combnV(4, 1:4)
combnV(4, 1:4, sum)
```

warning

Warning Messages

Description

Generates a warning message that corresponds to its argument(s) and (optionally) the expression or function from which it was called.

Usage

```
warning(..., call. = TRUE, immediate. = FALSE, noBreaks. = FALSE,
  domain = NULL)
suppressWarnings(expr, classes = "warning")
```

Arguments

... *either* zero or more objects which can be coerced to character (and which are pasted together with no separator) *or* a single [condition](#) object.

<code>call.</code>	logical, indicating if the call should become part of the warning message.
<code>immediate.</code>	logical, indicating if the warning should be output immediately, even if <code>getOption("warn") <= 0</code> . NB: this is not respected for condition objects.
<code>noBreaks.</code>	logical, indicating as far as possible the message should be output as a single line when <code>options(warn = 1)</code> .
<code>expr</code>	expression to evaluate.
<code>domain</code>	see <code>gettext</code> . If NA, messages will not be translated, see also the note in <code>stop</code> .
<code>classes</code>	character, indicating which classes of warnings should be suppressed.

Details

The result *depends* on the value of `options("warn")` and on handlers established in the executing code.

If a `condition` object is supplied it should be the only argument, and further arguments will be ignored, with a message. `options(warn = 1)` can be used to request an immediate report.

`warning` signals a warning condition by (effectively) calling `signalCondition`. If there are no handlers or if all handlers return, then the value of `warn = getOption("warn")` is used to determine the appropriate action. If `warn` is negative warnings are ignored; if it is zero they are stored and printed after the top-level function has completed; if it is one they are printed as they occur and if it is 2 (or larger) warnings are turned into errors. Calling `warning(immediate. = TRUE)` turns `warn <= 0` into `warn = 1` for this call only.

If `warn` is zero (the default), a read-only variable `last.warning` is created. It contains the warnings which can be printed via a call to `warnings`.

Warnings will be truncated to `getOption("warning.length")` characters, default 1000, indicated by `[... truncated]`.

While the warning is being processed, a `muffleWarning` restart is available. If this restart is invoked with `invokeRestart`, then `warning` returns immediately.

An attempt is made to coerce other types of inputs to `warning` to character vectors.

`suppressWarnings` evaluates its expression in a context that ignores all warnings.

Value

The warning message as `character` string, invisibly.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`stop` for fatal errors, `message` for diagnostic messages, `warnings`, and `options` with argument `warn=`.

`gettext` for the mechanisms for the automated translation of messages.

Examples

```
testit <- function() warning("testit")
testit() ## shows call
testit <- function() warning("problem in testit", call. = FALSE)
testit() ## no call
suppressWarnings(warning("testit"))
```

warnings

Print Warning Messages

Description

warnings and its print method print the variable `last.warning` in a pleasing form.

Usage

```
warnings(...)

## S3 method for class 'warnings'
summary(object, ...)

## S3 method for class 'warnings'
print(x, tags,
      header = ngettext(n, "Warning message:\n", "Warning messages:\n"),
      ...)
## S3 method for class 'summary.warnings'
print(x, ...)
```

Arguments

<code>...</code>	arguments to be passed to <code>cat</code> (for <code>warnings()</code>).
<code>object</code>	a "warnings" object as returned by <code>warnings()</code> .
<code>x</code>	a "warnings" or "summary.warnings" object.
<code>tags</code>	if not <code>missing</code> , a <code>character</code> vector of the same <code>length</code> as <code>x</code> , to "label" the messages. Defaults to <code>paste0(seq_len(n), ": ")</code> for $n \geq 2$ where $n \leftarrow \text{length}(x)$.
<code>header</code>	a character string <code>cat()</code> ed before the messages are printed.

Details

See the description of `options("warn")` for the circumstances under which there is a `last.warning` object and `warnings()` is used. In essence this is if `options(warn = 0)` and `warning` has been called at least once.

Note that the `length(last.warning)` is maximally `getOption("nwarnings")` (at the time the warnings are generated) which is 50 by default. To increase, use something like

```
options(nwarnings = 10000)
```

It is possible that `last.warning` refers to the last recorded warning and not to the last warning, for example if `options(warn)` has been changed or if a catastrophic error occurred.

Value

`warnings()` returns an object of S3 class "warnings", basically a named [list](#). In R versions before 4.4.0, it returned `NULL` when there were no warnings, contrary to the above documentation.

`summary(<warnings>)` returns a "summary.warnings" object which is basically the [list](#) of unique warnings (`unique(object)`) with a "counts" attribute, somewhat experimentally.

Warning

It is undocumented where `last.warning` is stored nor that it is visible, and this is subject to change.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[warning](#).

Examples

```
## NB this example is intended to be pasted in,
##      rather than run by example()
ow <- options("warn")
for(w in -1:1) {
  options(warn = w); cat("\n warn =", w, "\n")
  for(i in 1:3) { cat(i, "..\n"); m <- matrix(1:7, 3,4) }
  cat("-----\n")
}
## at the end prints all three warnings, from the 'option(warn = 0)' above
options(ow) # reset to previous, typically 'warn = 0'
tail(warnings(), 2) # see the last two warnings only (via '[' method)

## Often the most useful way to look at many warnings:
summary(warnings())

op <- options(nwarnings = 10000) ## <- get "full statistics"
x <- 1:36; for(n in 1:13) for(m in 1:12) A <- matrix(x, n,m) # There were 105 warnings ..
summary(warnings())
options(op) # revert to previous (keeping 50 messages by default)
```

weekdays

Extract Parts of a POSIXt or Date Object

Description

Extract the weekday, month or quarter, or the Julian time (days since some origin). These are generic functions: the methods for the internal date-time classes are documented here.

Usage

```

weekdays(x, abbreviate)
## S3 method for class 'POSIXt'
weekdays(x, abbreviate = FALSE)
## S3 method for class 'Date'
weekdays(x, abbreviate = FALSE)

months(x, abbreviate)
## S3 method for class 'POSIXt'
months(x, abbreviate = FALSE)
## S3 method for class 'Date'
months(x, abbreviate = FALSE)

quarters(x, abbreviate)
## S3 method for class 'POSIXt'
quarters(x, ...)
## S3 method for class 'Date'
quarters(x, ...)

julian(x, ...)
## S3 method for class 'POSIXt'
julian(x, origin = as.POSIXct("1970-01-01", tz = "GMT"), ...)
## S3 method for class 'Date'
julian(x, origin = as.Date("1970-01-01"), ...)

```

Arguments

<code>x</code>	an object inheriting from class "POSIXt" or "Date".
<code>abbreviate</code>	logical vector (possibly recycled). Should the names be abbreviated?
<code>origin</code>	an length-one object inheriting from class "POSIXt" or "Date".
<code>...</code>	arguments for other methods.

Value

`weekdays` and `months` return a character vector of names in the locale in use, i.e., `Sys.getlocale("LC_TIME")`.

`quarters` returns a character vector of "Q1" to "Q4".

`julian` returns the number of days (possibly fractional) since the origin, with the origin as a "origin" attribute. All time calculations in R are done ignoring leap-seconds.

Note

Other components such as the day of the month or the year are very easy to compute: just use `as.POSIXlt` and extract the relevant component. Alternatively (especially if the components are desired as character strings), use `strftime`.

See Also

`DateTimeClasses`, `Date`; `Sys.getlocale("LC_TIME")` crucially for `months()` and `weekdays()`.

Examples

```
## first two are locale dependent:
weekdays(.leap.seconds)
months    (.leap.seconds)
quarters(.leap.seconds)

## Show how easily you get month, day, year, day (of {month, week, yr}), ... :
## (remember to count from 0 (!): mon = 0..11, wday = 0..6, etc !!)

##' Transform (Time-)Date vector to convenient data frame :
dt2df <- function(dt, dName = deparse(substitute(dt))) {
  DF <- as.data.frame(unclass(as.POSIXlt( dt )))
  `names<-`(cbind(dt, DF, deparse.level=0L), c(dName, names(DF)))
}
## e.g.,
dt2df(.leap.seconds)      # date+time
dt2df(Sys.Date() + 0:9)  # date

##' Even simpler: Date -> Matrix - dropping time info {sec,min,hour, isdst}
d2mat <- function(x) simplify2array(unclass(as.POSIXlt(x))[4:7])
## e.g.,
d2mat(seq(as.Date("2000-02-02"), by=1, length.out=30)) # has R 1.0.0's release date

## Julian Day Number (JDN, https://en.wikipedia.org/wiki/Julian\_day)
## is the number of days since noon UTC on the first day of 4317 BCE.
## in the proleptic Julian calendar. To more recently, in
## 'Terrestrial Time' which differs from UTC by a few seconds
## See https://en.wikipedia.org/wiki/Terrestrial\_Time
julian(Sys.Date(), -2440588) # from a day
floor(as.numeric(julian(Sys.time())) + 2440587.5) # from a date-time
```

which

Which indices are TRUE?

Description

Give the TRUE indices of a logical object, allowing for array indices.

Usage

```
which(x, arr.ind = FALSE, useNames = TRUE)
arrayInd(ind, .dim, .dimnames = NULL, useNames = FALSE)
```

Arguments

<code>x</code>	a logical vector or array. NAs are allowed and omitted (treated as if FALSE).
<code>arr.ind</code>	logical; should array indices be returned when <code>x</code> is an array? Anything other than a single true value is treated as false.
<code>ind</code>	integer-valued index vector, as resulting from <code>which(x)</code> .
<code>.dim</code>	<code>dim(.)</code> integer vector.

<code>.dimnames</code>	optional list of character <code>dimnames(.)</code> . If <code>useNames</code> is true, to be used for constructing <code>dimnames</code> for <code>arrayInd()</code> (and hence, <code>which(*, arr.ind=TRUE)</code>). If <code>names(.dimnames)</code> is not empty, these are used as column names. <code>.dimnames[[1]]</code> is used as row names.
<code>useNames</code>	logical indicating if the value of <code>arrayInd()</code> should have (non-null) <code>dimnames</code> at all.

Value

If `arr.ind == FALSE` (the default), an integer vector, or a double vector if `x` is a *long vector*, with `length` equal to `sum(x)`, i.e., to the number of `TRUE`s in `x`.

Basically, the result is `(1:length(x))[x]` in typical cases; more generally, including when `x` has `NA`'s, `which(x)` is `seq_along(x)[!is.na(x) & x]` plus `names` when `x` has.

If `arr.ind == TRUE` and `x` is an *array* (has a `dim` attribute), the result is `arrayInd(which(x), dim(x), dimnames(x))`, namely a matrix whose rows each are the indices of one element of `x`; see Examples below.

Note

Unlike most other base R functions this does not coerce `x` to logical: only arguments with `typeof` logical are accepted and others give an error.

Author(s)

Werner Stahel and Peter Holzer (ETH Zurich) proposed the `arr.ind` option.

See Also

`Logic`, `which.min` for the index of the minimum or maximum, and `match` for the first index of an element in a vector, i.e., for a scalar `a`, `match(a, x)` is equivalent to `min(which(x == a))` but much more efficient.

Examples

```
which(LETTERS == "R")
which(11 <- c(TRUE, FALSE, TRUE, NA, FALSE, FALSE, TRUE)) #> 1 3 7
names(11) <- letters[seq(11)]
which(11)
which((1:12)%%2 == 0) # which are even?
which(1:10 > 3, arr.ind = TRUE)

( m <- matrix(1:12, 3, 4) )
div.3 <- m %% 3 == 0
which(div.3)
which(div.3, arr.ind = TRUE)
rownames(m) <- paste("Case", 1:3, sep = "_")
which(m %% 5 == 0, arr.ind = TRUE)

dim(m) <- c(2, 2, 3); m
which(div.3, arr.ind = FALSE)
which(div.3, arr.ind = TRUE)

vm <- c(m)
dim(vm) <- length(vm) #-- funny thing with length(dim(...)) == 1
```

```
which(div.3, arr.ind = TRUE)
```

which.min

Where is the Min() or Max() or first TRUE or FALSE ?

Description

Determines the location, i.e., index of the (first) minimum or maximum of a numeric (or logical) vector.

Usage

```
which.min(x)
which.max(x)
```

Arguments

x numeric (logical, integer or double) vector or an R object for which `xtfrm` or the internal coercion to `double` (the former if `x` has a class attribute) works, whose `min` or `max` is searched for.

Details

For compatibility with R < 4.6, `data frames` `x` are handled as if without a class attribute.

Value

Missing and NaN values are discarded.

an `integer` or on 64-bit platforms, if `length(x) == 2^31` an integer valued `double` of length 1 or 0 (iff `x` has no non-NA's), giving the index of the *first* minimum or maximum respectively of `x`.

If this extremum is unique (or empty), the results are the same as (but more efficient than) `which(x == min(x, na.rm = TRUE))` or `which(x == max(x, na.rm = TRUE))` respectively.

Logical `x` – First TRUE or FALSE

For a `logical` vector `x` with both FALSE and TRUE values, `which.min(x)` and `which.max(x)` return the index of the first FALSE or TRUE, respectively, as FALSE < TRUE. However, `match(FALSE, x)` or `match(TRUE, x)` are typically *preferred*, as they do indicate mismatches.

Author(s)

Martin Maechler

See Also

`which`, `max.col`, `max`, etc.

Use `arrayInd()`, if you need array/matrix indices instead of 1D vector ones.

`which.is.max` in package **nnet** differs in breaking ties at random (and having a ‘fuzz’ in the definition of ties).

Examples

```

x <- c(1:4, 0:5, 11)
which.min(x)
which.max(x)

## it *does* work with NAs present, by discarding them:
presidents[1:30]
range(presidents, na.rm = TRUE)
which.min(presidents) # 28
which.max(presidents) # 2

## Find the first occurrence, i.e. the first TRUE, if there is at least one:
x <- rpois(10000, lambda = 10); x[sample.int(50, 20)] <- NA
## where is the first value >= 20 ?
which.max(x >= 20)

## Also works for lists (which can be coerced to numeric vectors):
which.min(list(A = 7, pi = pi)) ## -> c(pi = 2L)

## Supports classes with methods for xtfrm() since R 4.6 (PR#18983):
(vv <- numeric_version(c("1.1.1", "1.1.1", "1.1", "1", "1")))
xtfrm(vv) # 4 4 3 1 1
stopifnot(identical(which.min(vv), 4L),
           identical(which.max(vv), 1L))

```

with

*Evaluate an Expression in a Data Environment***Description**

Evaluate an R expression in an environment constructed from data, possibly modifying (a copy of) the original data.

Usage

```

with(data, expr, ...)
within(data, expr, ...)
## S3 method for class 'list'
within(data, expr, keepAttrs = TRUE, ...)

```

Arguments

data	data to use for constructing an environment. For the default <code>with</code> method this may be an environment, a list, a data frame, or an integer as in <code>sys.call</code> . For <code>within</code> , it can be a list or a data frame.
expr	expression to evaluate; particularly for <code>within()</code> often a “compound” expression, i.e., of the form <pre> { a <- somefun() b <- otherfun() }</pre>

```

        rm(unused1, temp)
      }
keepAttrs    for the list method of within(), a logical specifying if the resulting
              list should keep the attributes from data and have its names in the same
              order. Often this is unneeded as the result is a named list anyway, and then
              keepAttrs = FALSE is more efficient.
...          arguments to be passed to (future) methods.

```

Details

`with` is a generic function that evaluates `expr` in a local environment constructed from `data`. The environment has the caller's environment as its parent. This is useful for simplifying calls to modeling functions. (Note: if `data` is already an environment then this is used with its existing parent.)

Note that assignments within `expr` take place in the constructed environment and not in the user's workspace.

`within` is similar, except that it examines the environment after the evaluation of `expr` and makes the corresponding modifications to a copy of `data` (this may fail in the data frame case if objects are created which cannot be stored in a data frame), and returns it. `within` can be used as an alternative to `transform`.

Value

For `with`, the value of the evaluated `expr`. For `within`, the modified object.

Note

For *interactive* use this is very effective and nice to read. For *programming* however, i.e., in one's functions, more care is needed, and typically one should refrain from using `with()`, as, e.g., variables in `data` may accidentally override local variables, see the reference.

Further, when using modeling or graphics functions with an explicit `data` argument (and typically using `formulas`), it is typically preferred to use the `data` argument of that function rather than to use `with(data, ...)`.

References

See Also

`evalq`, `attach`, `assign`, `transform`.

Examples

```

with(mtcars, mpg[cyl == 8 & disp > 350])
# is the same as, but nicer than
mtcars$mpg[mtcars$cyl == 8 & mtcars$disp > 350]

require(stats); require(graphics)

# examples from glm:
with(data.frame(u = c(5,10,15,20,30,40,60,80,100)),

```

```

      lot1 = c(118,58,42,35,27,25,21,19,18),
      lot2 = c(69,35,26,21,18,16,13,12,12)),
  list(summary(glm(lot1 ~ log(u), family = Gamma)),
        summary(glm(lot2 ~ log(u), family = Gamma)))

aq <- within(airquality, {      # Notice that multiple vars can be changed
  lOzone <- log(Ozone)
  Month <- factor(month.abb[Month])
  cTemp <- round((Temp - 32) * 5/9, 1) # From Fahrenheit to Celsius
  S.cT <- Solar.R / cTemp # using the newly created variable
  rm(Day, Temp)
})
head(aq)

# example from boxplot:
with(ToothGrowth, {
  boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
    subset = (supp == "VC"), col = "yellow",
    main = "Guinea Pigs' Tooth Growth",
    xlab = "Vitamin C dose mg",
    ylab = "tooth length", ylim = c(0, 35))
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
    subset = supp == "OJ", col = "orange")
  legend(2, 9, c("Ascorbic acid", "Orange juice"),
    fill = c("yellow", "orange"))
})

# alternate form that avoids subset argument:
with(subset(ToothGrowth, supp == "VC"),
  boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
    col = "yellow", main = "Guinea Pigs' Tooth Growth",
    xlab = "Vitamin C dose mg",
    ylab = "tooth length", ylim = c(0, 35)))
with(subset(ToothGrowth, supp == "OJ"),
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
    col = "orange"))
legend(2, 9, c("Ascorbic acid", "Orange juice"),
  fill = c("yellow", "orange"))

```

withVisible

Return both a Value and its Visibility

Description

This function evaluates an expression, returning it in a two element list containing its value and a flag showing whether it would automatically print.

Usage

```
withVisible(x)
```

Arguments

`x` an expression to be evaluated.

Details

The argument, *not* an [expression](#) object, rather an (unevaluated function) [call](#), is evaluated in the caller's context.

This is a [primitive](#) function.

Value

`value` The value of `x` after evaluation.

`visible` logical; whether the value would auto-print.

See Also

[invisible](#), [eval](#); [withAutoprint\(\)](#) calls [source\(\)](#) which itself uses [withVisible\(\)](#) in order to correctly “auto print”.

Examples

```
x <- 1
withVisible(x <- 1) # *$visible is FALSE
x
withVisible(x)      # *$visible is TRUE

# Wrap the call in evalq() for special handling

df <- data.frame(a = 1:5, b = 1:5)
evalq(withVisible(a + b), envir = df)
```

write

Write Data to a File

Description

Write data `x` to a file or other [connection](#).

As it simply calls [cat\(\)](#), less formatting happens than with [print\(\)](#)ing. If `x` is a matrix you need to transpose it (and typically set `ncolumns`) to get the columns in `file` the same as those in the internal representation.

Whereas atomic vectors ([numeric](#), [character](#), etc, including matrices) are written plainly, i.e., without any names, less simple vector-like objects such as `"factor"`, `"Date"`, or `"POSIXt"` may be [formatted](#) to character before writing.

Usage

```
write(x, file = "data",
      ncolumns = if(is.character(x)) 1 else 5,
      append = FALSE, sep = " ")
```

Arguments

x	the data to be written out.
file	a connection , or a character string naming the file to write to. If "", print to the standard output connection, i.e., "" is equivalent to <code>stdout()</code> here. When <code>.Platform\$OS.type != "windows"</code> , and it is " <code> cmd</code> ", the output is piped to the command given by ' <code>cmd</code> '.
ncolumns	the number of columns to write the data in.
append	if TRUE the data x are appended to the connection.
sep	a string used to separate columns. Using <code>sep = "\t"</code> gives tab delimited output; default is " ".

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

`write` is a wrapper for [cat](#), which gives further details on the format used.

[write.table](#) for matrix and data frame objects, [writeLines](#) for lines of text, and [scan](#) for reading data.

[saveRDS](#) and [save](#) are often preferable (for writing any R objects).

Examples

```
# Demonstrate default ncolumns, writing to the console
write(month.abb, "") # 1 element per line for "character"
write(stack.loss, "") # 5 elements per line for "numeric"

# Build a file with sequential calls
fil <- tempfile("data")
write("# Model settings", fil)
write(month.abb, fil, ncolumns = 6, append = TRUE)
write("\n# Initial parameter values", fil, append = TRUE)
write(sqrt(stack.loss), fil, append = TRUE)
if(interactive()) file.show(fil)
unlink(fil) # tidy up
```

writeLines

Write Lines to a Connection

Description

Write text lines to a connection.

Usage

```
writeLines(text, con = stdout(), sep = "\n", useBytes = FALSE)
```

Arguments

<code>text</code>	a character vector.
<code>con</code>	a connection object or a character string.
<code>sep</code>	character string. A string to be written to the connection after each line of text.
<code>useBytes</code>	logical. See ‘Details’.

Details

If the `con` is a character string, the function calls [file](#) to obtain a file connection which is opened for the duration of the function call. ([tilde expansion](#) of the file path is done by `file`.)

If the connection is open it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.

Normally `writeLines` is used with a text-mode connection, and the default separator is converted to the normal separator for that platform (LF on Unix/Linux, CRLF on Windows). For more control, open a binary connection and specify the precise value you want written to the file in `sep`. For even more control, use [writeChar](#) on a binary connection.

`useBytes` is for expert use. Normally (when false) character strings with marked encodings are converted to the current encoding before being passed to the connection (which might do further re-encoding). `useBytes = TRUE` suppresses the re-encoding of marked strings so they are passed byte-by-byte to the connection: this can be useful when strings have already been re-encoded by e.g. [iconv](#). (It is invoked automatically for strings with marked encoding "bytes".)

See Also

[connections](#), [writeChar](#), [writeBin](#), [readLines](#), [cat](#)

xtfrm

Auxiliary Function for Sorting and Ranking

Description

A generic auxiliary function that produces a numeric vector which will sort in the same order as `x`.

Usage

```
xtfrm(x)
```

Arguments

`x` an R object.

Details

This is a special case of ranking, but as a less general function than [rank](#) is more suitable to be made generic. The default method is similar to `rank(x, ties.method = "min", na.last = "keep")`, so NA values are given rank NA and all tied values are given equal integer rank.

The [factor](#) method extracts the codes.

The default method will unclass the object if `is.numeric(x)` is true but otherwise make use of `==` and `>` methods for the class of `x[i]` (for integers `i`), and the `is.na` method for the class of `x`, but might be rather slow when doing so.

This is an [internal generic primitive](#), so S3 or S4 methods can be written for it. Differently to other internal generics, the default method is called explicitly when no other dispatch has happened.

Value

A numeric (usually integer) vector of the same length as `x`.

See Also

[rank](#), [sort](#), [order](#).

zapsmall

Rounding of Numbers: Zapping Small Ones to Zero

Description

`zapsmall` determines a `digits` argument `dr` for calling `round(x, digits = dr)` such that values close to zero (compared with the maximal absolute value in the vector) are ‘zapped’, i.e., replaced by 0. `digits = Inf` keeps the full precision, returning `x` unchanged.

Usage

```
zapsmall(x, digits = getOption("digits"),
        mFUN = function(x, ina) max(abs(x[!ina])),
        min.d = 0L)
```

Arguments

<code>x</code>	a numeric or complex vector or any R number-like object which has a round method and basic arithmetic methods including log10() .
<code>digits</code>	integer indicating the precision to be used.
<code>mFUN</code>	a function (<code>x</code> , <code>ina</code>) of the numeric (or complex) <code>x</code> and the logical <code>ina := is.na(x)</code> returning a positive number in the order of magnitude of the maximal <code>abs(x)</code> value. The default is back compatible but not robust, and e.g., not very useful when <code>x</code> has infinite entries.
<code>min.d</code>	an integer specifying the minimal number of digits to use in the resulting round (<code>x</code> , <code>digits=*</code>) call when <code>mFUN(*) > 0</code> . Using <code>min.d = -324</code> or smaller provides scale invariance, whereas the default <code>min.d = 0</code> is back compatible with S and R versions before 4.4.0 where, it was implicitly hardwired to 0 with the intuition that e.g., 4 should never be zapped to 0.

References

Chambers JM (1998). *Programming with Data*. Springer, New York. ISBN 978-0-387-98503-9.

Examples

```

x2 <- pi * 100^(-2:2)/10
print( x2, digits = 4)
zapsmall( x2) # automatic digits
zapsmall( x2, digits = 4) # 0 0 0.3 ...
zapsmall(1e6*x2, digits = 4) # no zeros (*not* scale invariant)
zapsmall(1e6*x2, digits = 4, min.d = -324) # 0 0 .. *is* scale inv.
zapsmall(c(x2, Inf)) # round()s to integer, as min.d = 0
zapsmall(c(x2, Inf), min.d=-Inf) # 0 0 .. 0 Inf -- everything is small wrt Inf

(z <- exp(1i*0:4*pi/2))
zapsmall(z)

zapShow <- function(x, ...) rbind(orig = x, zapped = zapsmall(x, ...))
zapShow(x2)

## using a *robust* mFUN
mF_rob <- function(x, ina) boxplot.stats(x, do.conf=FALSE)$stats[5]
## a simpler robust one:
mF_Q3 <- function(x, ina) { x <- abs(x[is.finite(x)])
  if(length(x <- x[x > 0])) quantile(x, 3/4, names=FALSE) else 0 }
## at least "protect from Inf":
mF_mxF <- function(x, ina) max(abs(x[is.finite(x)]))
## with robust mFUN(), 'Inf' is no longer distorting the picture:
zapShow(c(x2, Inf), mFUN = mF_Q3) # no zapping
zapShow(c(x2, Inf), mFUN = mF_Q3, min.d = -5) # the same
zapShow(c(x2, Inf), mFUN = mF_Q3, min.d = -324) # same
zapShow(c(x2, 9999), mFUN = mF_Q3) # zap 1st
zapShow(c(x2, 9999), mFUN = mF_Q3, min.d = 3) # the same
zapShow(c(x2, 9999), mFUN = mF_Q3, min.d = -324) # ditto
zapShow(c(x2, 9999), mFUN = mF_Q3, min.d = 8) # no zap

zapShow(c(x2, Inf), mFUN = mF_mxF) # no zapping
zapShow(c(x2, Inf), mFUN = mF_mxF, min.d = -5) # the same
zapShow(c(x2, Inf), mFUN = mF_mxF, min.d = -324) # same
zapShow(c(x2, 9999), mFUN = mF_mxF)
zapShow(c(x2, 9999), mFUN = mF_mxF, min.d = 3) # the same
zapShow(c(x2, 9999), mFUN = mF_mxF, min.d = -324) # ditto
zapShow(c(x2, 9999), mFUN = mF_mxF, min.d = 8) # small diff

zapShow(c(x2, Inf), mFUN = mF_rob)
zapShow(c(x2, Inf), mFUN = mF_rob, min.d = -5) # the same
zapShow(c(x2, 9999), mFUN = mF_rob) # same *rounding* as w/ Inf
zapShow(c(x2, 9999), mFUN = mF_rob, min.d = 3) # the same
zapShow(c(x2, 9999), mFUN = mF_rob, min.d = 8) # small diff

```

Description

.packages returns information about package availability.

Usage

```
.packages(all.available = FALSE, lib.loc = NULL)
```

Arguments

`all.available`
logical; if TRUE return a character vector of all available packages in `lib.loc`.

`lib.loc`
a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to `.libPaths()`.

Details

`.packages()` returns the names of the currently attached packages *invisibly* whereas `.packages(all.available = TRUE)` gives (visibly) *all* packages available in the library location path `lib.loc`.

For a package to be regarded as being ‘available’ it must have valid metadata (and hence be an installed package). However, this will report a package as available if the metadata does not match the directory name: use `find.package` to confirm that the metadata match or `installed.packages` for a much slower but more comprehensive check of ‘available’ packages.

Value

A character vector of package base names, invisible unless `all.available = TRUE`.

Note

`.packages(all.available = TRUE)` is not a way to find out if a small number of packages are available for use: not only is it expensive when thousands of packages are installed, it is an incomplete test. See the help for `find.package` for why `require` should be used.

Author(s)

R core; Guido Masarotto for the `all.available = TRUE` part of `.packages`.

See Also

`library`, `.libPaths`, `installed.packages`.

Examples

```
(.packages()) # maybe just "base"
.packages(all.available = TRUE) # return all available as character vector
require(splines)
.packages() # "splines", too
detach("package:splines")
```

zutils*Miscellaneous Internal/Programming Utilities*

Description

Miscellaneous internal/programming utilities.

Usage

```
.standard_regexps()
```

Details

`.standard_regexps` returns a list of ‘standard’ regexps, including elements named `valid_package_name` and `valid_package_version` with the obvious meanings. The regexps are not anchored.

Chapter 2

The compiler package

compile

Byte Code Compiler

Description

These functions provide an interface to a byte code compiler for R.

Usage

```
cmpfun(f, options = NULL)
compile(e, env = .GlobalEnv, options = NULL, srcref = NULL)
cmpfile(infile, outfile, ascii = FALSE, env = .GlobalEnv,
         verbose = FALSE, options = NULL, version = NULL)
loadcmp(file, envir = .GlobalEnv, chdir = FALSE)
disassemble(code)
enableJIT(level)
compilePKGS(enable)
getCompilerOption(name, options)
setCompilerOptions(...)
```

Arguments

<code>f</code>	a closure.
<code>options</code>	list of named compiler options: see ‘Details’.
<code>env</code>	the top level environment for the compiling.
<code>srcref</code>	initial source reference for the expression.
<code>file, infile, outfile</code>	pathnames; <code>outfile</code> defaults to <code>infile</code> with a ‘.Rc’ extension in place of any existing extension.
<code>ascii</code>	logical; should the compiled file be saved in ascii format?
<code>verbose</code>	logical; should the compiler show what is being compiled?
<code>version</code>	the workspace format version to use. <code>NULL</code> specifies the current default format (3). Version 1 was the default from R 0.99.0 to R 1.3.1 and version 2 from R 1.4.0 to 3.5.0. Version 3 is supported from R 3.5.0.

<code>envir</code>	environment to evaluate loaded expressions in.
<code>chdir</code>	logical; change directory before evaluation?
<code>code</code>	byte code expression or compiled closure
<code>e</code>	expression to compile.
<code>level</code>	integer; the JIT level to use (0 to 3, or negative to <i>return</i> it).
<code>enable</code>	logical; enable compiling packages if TRUE.
<code>name</code>	character string; name of option to return.
<code>...</code>	named compiler options to set.

Details

The function `cmpfun` compiles the body of a closure and returns a new closure with the same formals and the body replaced by the compiled body expression.

`compile` compiles an expression into a byte code object; the object can then be evaluated with `eval`.

`cmpfile` parses the expressions in `infile`, compiles them, and writes the compiled expressions to `outfile`. If `outfile` is not provided, it is formed from `infile` by replacing or appending a `.Rc` suffix.

`loadcmp` is used to load compiled files. It is similar to `sys.source`, except that its default loading environment is the global environment rather than the base environment.

`disassemble` produces a printed representation of the code that may be useful to give a hint of what is going on.

`enableJIT` enables or disables just-in-time (JIT) compilation. JIT is disabled if the argument is 0. If `level` is 1 then larger closures are compiled before their first use. If `level` is 2, then some small closures are also compiled before their second use. If `level` is 3 then in addition all top level loops are compiled before they are executed. JIT level 3 requires the compiler option `optimize` to be 2 or 3. The JIT level can also be selected by starting R with the environment variable `R_ENABLE_JIT` set to one of these values. Calling `enableJIT` with a negative argument returns the current JIT level. The default JIT level is 3.

`compilePKGS` enables or disables compiling packages when they are installed. This requires that the package uses lazy loading as compilation occurs as functions are written to the lazy loading data base. This can also be enabled by starting R with the environment variable `_R_COMPILE_PKGS_` set to a positive integer value. This should not be enabled outside package installation, because it causes any serialized function to be compiled, which comes with time and space overhead. `R_COMPILE_PKGS` can be used, instead, to instruct `INSTALL` to enable/disable compilation of packages during installation.

Currently the compiler warns about a variety of things. It does this by using `cat` to print messages. Eventually this should use the condition handling mechanism.

The `options` argument can be used to control compiler operation. There are currently four options: `optimize`, `suppressAll`, `suppressUndefined`, and `suppressNoSuperAssignVar`. `optimize` specifies the optimization level, an integer from 0 to 3 (the current out-of-the-box default is 2). `suppressAll` should be a scalar logical; if TRUE no messages will be shown (this is the default). `suppressUndefined` can be TRUE to suppress all messages about undefined variables, or it can be a character vector of the names of variables for which messages should not be shown. `suppressNoSuperAssignVar` can be TRUE to suppress messages about super assignments to a variable for which no binding is visible at compile time. During compilation of packages, `suppressAll` is currently FALSE, `suppressUndefined` is TRUE and `suppressNoSuperAssignVar` is TRUE.

`getCompilerOption` returns the value of the specified option. The default value is returned unless a value is supplied in the `options` argument; the `options` argument is primarily for internal use. `setCompilerOption` sets the default option values. Options to set are identified by argument names, e.g. `setCompilerOptions(suppressAll = TRUE, optimize = 3)`. It returns a named list of the previous values.

Calling the compiler a byte code compiler is actually a bit of a misnomer: the external representation of code objects currently uses `int` operands, and when compiled with `gcc` the internal representation is actually threaded code rather than byte code.

Chapter 3

The datasets package

<code>datasets-package</code>	<i>The R Datasets Package</i>
-------------------------------	-------------------------------

Description

Base R datasets

Details

This package contains a variety of datasets. For a complete list, use `library(help = "datasets")`.

Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

<code>ability.cov</code>	<i>Ability and Intelligence Tests</i>
--------------------------	---------------------------------------

Description

Six tests were given to 112 individuals. The covariance matrix is given in this object.

Usage

`ability.cov`

Details

The tests are described as

general: a non-verbal measure of general intelligence using Cattell's culture-fair test.

picture: a picture-completion test

blocks: block design

maze: mazes

reading: reading comprehension

vocab: vocabulary

Bartholomew gives both covariance and correlation matrices, but these are inconsistent. Neither are in the original paper.

```

```
## Structural Time Series
ap <- log10(AirPassengers) - 2
(fit <- StructTS(ap, type = "BSM"))
par(mfrow = c(1, 2))
plot(cbind(ap, fitted(fit)), plot.type = "single")
plot(cbind(ap, tsSmooth(fit)), plot.type = "single")
```

airquality

New York Air Quality Measurements

Description

Daily air quality measurements in New York, May to September 1973.

Usage

```
airquality
```

Format

A data frame with 153 observations on 6 variables.

[, 1]	Ozone	numeric	Ozone (ppb)
[, 2]	Solar.R	numeric	Solar R (lang)
[, 3]	Wind	numeric	Wind (mph)
[, 4]	Temp	numeric	Temperature (degrees F)
[, 5]	Month	numeric	Month (1–12)
[, 6]	Day	numeric	Day of month (1–31)

Details

Daily readings of the following air quality values for May 1, 1973 (a Tuesday) to September 30, 1973.

- **Ozone:** Mean ozone in parts per billion from 1300 to 1500 hours at Roosevelt Island
- **Solar.R:** Solar radiation in Langleys in the frequency band 4000–7700 Angstroms from 0800 to 1200 hours at Central Park
- **Wind:** Average wind speed in miles per hour at 0700 and 1000 hours at LaGuardia Airport
- **Temp:** Maximum daily temperature in degrees Fahrenheit at LaGuardia Airport.

Source

The data were obtained from the New York State Department of Conservation (ozone data) and the National Weather Service (meteorological data).

par(op)
```

attenu

The Joyner–Boore Attenuation Data

Description

This data gives peak accelerations measured at various observation stations for 23 earthquakes in California. The data have been used by various workers to estimate the attenuating affect of distance on ground acceleration.

Usage

attenu

Format

A data frame with 182 observations on 5 variables.

[,1]	event	numeric	Event Number
[,2]	mag	numeric	Moment Magnitude
[,3]	station	factor	Station Number
[,4]	dist	numeric	Station-hypocenter distance (km)
[,5]	accel	numeric	Peak acceleration (g)

       data = attenu, panel = panel.smooth, show.given = FALSE)
```

attitude

The Chatterjee–Price Attitude Data

Description

From a survey of the clerical employees of a large financial organization, the data are aggregated from the questionnaires of the approximately 35 employees for each of 30 (randomly selected) departments. The numbers give the percent proportion of favourable responses to seven questions in each department.

Usage

```
attitude
```

Format

A data frame with 30 observations on 7 variables. The first column are the short names from the reference, the second one the variable names in the data frame:

Y	rating	numeric	Overall rating
X[1]	complaints	numeric	Handling of employee complaints
X[2]	privileges	numeric	Does not allow special privileges
X[3]	learning	numeric	Opportunity to learn
X[4]	raises	numeric	Raises based on performance
X[5]	critical	numeric	Too critical
X[6]	advance	numeric	Advancement

            mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
summary(fm2 <- lm(rating ~ complaints, data = attitude))
plot(fm2)
par(opar)
```

austres

Quarterly Time Series of the Number of Australian Residents

Description

Numbers (in thousands) of Australian residents measured quarterly from March 1971 to March 1994. The object is of class "ts".

Usage

```
austres
```

Source

Brockwell PJ, Davis RA (1996). *Introduction to Time Series and Forecasting*, series Springer Texts in Statistics. Springer, New York. doi:[10.1007/9781475725261](https://doi.org/10.1007/9781475725261).

beavers

Body Temperature Series of Two Beavers

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

```
beaver1
beaver2
```

Format

The `beaver1` data frame has 114 rows and 4 columns on body temperature measurements at 10 minute intervals.

The `beaver2` data frame has 100 rows and 4 columns on body temperature measurements at 10 minute intervals.

The variables are as follows:

`day` Day of observation (in days since the beginning of 1990), December 12–13 (`beaver1`) and November 3–4 (`beaver2`).

`time` Time of observation, in the form 0330 for 3:30am

`temp` Measured body temperature in degrees Celsius.

`activ` Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing in `beaver1`.

Source

Reynolds (1994)

References

Examples

```
require(graphics)
(yl <- range(beaver1$temp, beaver2$temp))

beaver.plot <- function(bdat, ...) {
  nam <- deparse(substitute(bdat))
  with(bdat, {
    # Hours since start of day:
    hours <- time %% 100 + 24*(day - day[1]) + (time %% 100)/60
    plot(hours, temp, type = "l", ...,
         main = paste(nam, "body temperature"))
    abline(h = 37.5, col = "gray", lty = 2)
    is.act <- activ == 1
    points(hours[is.act], temp[is.act], col = 2, cex = .8)
  })
}

op <- par(mfrow = c(2, 1), mar = c(3, 3, 4, 2), mgp = 0.9 * 2:0)
beaver.plot(beaver1, ylim = yl)
beaver.plot(beaver2, ylim = yl)
par(op)
```

BJsales

Sales Data with Leading Indicator

Description

The sales time series BJsales and leading indicator BJsales.lead each contain 150 observations. The objects are of class "ts".

Usage

```
BJsales
BJsales.lead
```

Source

The data are given in Box and Jenkins (1976, p. 537). Obtained from the Time Series Data Library at <https://robjhyndman.com/TSDL/>

BOD

Biochemical Oxygen Demand

Description

The BOD data frame has 6 rows and 2 columns giving the biochemical oxygen demand versus time in an evaluation of water quality.

Usage

```
BOD
```

Format

This data frame contains the following columns:

Time A numeric vector giving the time of the measurement (days).

demand A numeric vector giving the biochemical oxygen demand (mg/l).

ChickWeight

*Weight Versus Age of Chicks on Different Diets***Description**

The `ChickWeight` data frame has 578 rows and 4 columns from an experiment on the effect of diet on early growth of chicks.

Usage

```
ChickWeight
```

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

`weight` a numeric vector giving the body weight of the chick (gm).

`Time` a numeric vector giving the number of days since birth when the measurement was made.

`Chick` an ordered factor with levels '18' < ... < '48' giving a unique identifier for the chick. The ordering of the levels groups chicks on the same diet together and orders them according to their final weight (lightest to heaviest) within diet.

`Diet` a factor with levels '1', ..., '4' indicating which experimental diet the chick received.

Details

The body weights of the chicks were measured at birth and every second day thereafter until day 20. They were also measured on day 21. There were four groups of chicks on different protein diets.

This dataset was originally part of package **nlme**, and that has methods (including for `[, as.data.frame, plot` and `print`) for its grouped-data classes.

coplot(weight ~ Time | Chick, data = ChickWeight,
       type = "b", show.given = FALSE)
```

chickwts

Chicken Weights by Feed Type

Description

An experiment was conducted to measure and compare the effectiveness of various feed supplements on the growth rate of chickens.

Usage

```
chickwts
```

Format

A data frame with 71 observations on the following 2 variables.

`weight` a numeric variable giving the chick weight in grams.

`feed` a factor giving the feed type.

Details

Newly hatched chicks were randomly allocated into six groups, and each group was given a different feed supplement. Their weights in grams after six weeks are given along with feed types.

CO2

Carbon Dioxide Uptake in Grass Plants

Description

The CO2 data frame has 84 rows and 5 columns of data from an experiment on the cold tolerance of the grass species *Echinochloa crus-galli*.

Usage

CO2

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

Plant an ordered factor with levels `Qn1 < Qn2 < Qn3 < ... < Mc1` giving a unique identifier for each plant.

Type a factor with levels `Quebec Mississippi` giving the origin of the plant

Treatment a factor with levels `nonchilled chilled`

conc a numeric vector of ambient carbon dioxide concentrations (mL/L).

uptake a numeric vector of carbon dioxide uptake rates ($\mu\text{mol}/m^2 \text{ sec}$).

Details

The CO_2 uptake of six plants from Quebec and six plants from Mississippi was measured at several levels of ambient CO_2 concentration. Half the plants of each type were chilled overnight before the experiment was conducted.

This dataset was originally part of package **nlme** (Pinheiro and Bates 2000, Appendix A.5), and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

```
require(stats); require(graphics)

coplot(uptake ~ conc | Plant, data = CO2, show.given = FALSE, type = "b")
## fit the data for the first plant
fml <- nls(uptake ~ SSasym(conc, Asym, lrc, c0),
  data = CO2, subset = Plant == "Qn1")
summary(fml)
## fit each plant separately
fmlist <- list()
for (pp in levels(CO2$Plant)) {
  fmlist[[pp]] <- nls(uptake ~ SSasym(conc, Asym, lrc, c0),
    data = CO2, subset = Plant == pp)
}
## check the coefficients by plant
print(sapply(fmlist, coef), digits = 3)
```

co2

Mauna Loa Atmospheric CO2 Concentration

Description

Atmospheric concentrations of CO₂ are expressed in parts per million (ppm) and reported in the preliminary 1997 SIO manometric mole fraction scale.

Usage

```
co2
```

Format

A time series of 468 observations; monthly from 1959 to 1997.

Details

The values for February, March and April of 1964 were missing and have been obtained by interpolating linearly between the values for January and May of 1964.

plot(co2, ylab = expression("Atmospheric concentration of CO"[2]),
     las = 1)
title(main = "co2 data set")
```

crimtab

Student's 3000 Criminals Data

Description

Data of 3000 male criminals over 20 years old undergoing their sentences in the chief prisons of England and Wales.

Usage

```
crimtab
```

Format

A `table` object of `integer` counts, of dimension 42×22 with a total count, `sum(crimtab)` of 3000.

The 42 `rownames` ("9.4", "9.5", ...) correspond to midpoints of intervals of finger lengths whereas the 22 column names (`colnames`) ("142.24", "144.78", ...) correspond to (body) heights of 3000 criminals, see also below.

Details

Student is the pseudonym of William Sealy Gosset. In his 1908 paper he wrote (on page 13) at the beginning of section VI entitled *Practical Test of the forgoing Equations*:

“Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically. The material used was a correlation table containing the height and left middle finger measurements of 3000 criminals, from a paper by MacDonell (1902, p. 219). The measurements were written out on 3000 pieces of cardboard, which were then very thoroughly shuffled and drawn at random. As each card was drawn its numbers were written down in a book, which thus contains the measurements of 3000 criminals in a random order. Finally, each consecutive set of 4 was taken as a sample—750 in all—and the mean, standard deviation, and correlation of each sample determined. The difference between the mean of each sample and the mean of the population was then divided by the standard deviation of the sample, giving us the z of Section III.”

The table is in fact page 216 and not page 219 in MacDonell (1902). In the MacDonell table, the middle finger lengths were given in mm and the heights in feet/inches intervals, they are both converted into cm here. The midpoints of intervals were used, e.g., where MacDonell has $4'7''9/16 - 8''9/16$, we have 142.24 which is $2.54 * 56 = 2.54 * (4'8'')$.

MacDonell credited the source of data (page 178) as follows: “The data on which the memoir is based were obtained, through the kindness of Dr Garson, from the Central Metric Office, New Scotland Yard...” He pointed out on page 179 that : “The forms were drawn at random from the mass on the office shelves; we are therefore dealing with a random sampling.”

Source

References

Garson JG (1900). “The Metric System of Identification of Criminals, as Used in Great Britain and Ireland.” *The Journal of the Anthropological Institute of Great Britain and Ireland*, **30**, 161. doi:10.2307/2842627.

MacDonell WR (1902). “On Criminal Anthropometry and the Identification of Criminals.” *Biometrika*, **1**(2), 177–227. doi:10.1093/biomet/1.2.177.

Student (1908). “The Probable Error of a Mean.” *Biometrika*, **6**(1), 1. doi:10.2307/2331554.

Examples

```
require(stats)
dim(crimtab)
utils::str(crimtab)
## for nicer printing:
local({cT <- crimtab
      colnames(cT) <- substring(colnames(cT), 2, 3)
      print(cT, zero.print = " ")
})

## Repeat Student's experiment:

# 1) Reconstitute 3000 raw data for heights in inches and rounded to
#     nearest integer as in Student's paper:

(heIn <- round(as.numeric(colnames(crimtab)) / 2.54))
d.hei <- data.frame(height = rep(heIn, colSums(crimtab)))

# 2) shuffle the data:

set.seed(1)
d.hei <- d.hei[sample(1:3000), , drop = FALSE]

# 3) Make 750 samples each of size 4:

d.hei$sample <- as.factor(rep(1:750, each = 4))

# 4) Compute the means and standard deviations (n) for the 750 samples:

h.mean <- with(d.hei, tapply(height, sample, FUN = mean))
h.sd    <- with(d.hei, tapply(height, sample, FUN = sd)) * sqrt(3/4)
```

```
# 5) Compute the difference between the mean of each sample and
#     the mean of the population and then divide by the
#     standard deviation of the sample:

zobs <- (h.mean - mean(d.hei[, "height"])) / h.sd

# 6) Replace infinite values by +/- 6 as in Student's paper:

zobs[infZ <- is.infinite(zobs)] # none of them
zobs[infZ] <- 6 * sign(zobs[infZ])

# 7) Plot the distribution:

require(grDevices); require(graphics)
hist(x = zobs, probability = TRUE, xlab = "Student's z",
     col = grey(0.8), border = grey(0.5),
     main = "Distribution of Student's z score for 'crimtab' data")
```

discoveries

Yearly Numbers of Important Discoveries

Description

The numbers of “great” inventions and scientific discoveries in each year from 1860 to 1959.

Usage

```
discoveries
```

Format

A time series of 100 values.

Source

The World Almanac and Book of Facts, 1975 Edition, pages 315–318.

     las = 1)
title(main = "discoveries data set")
```

DNase

*Elisa assay of DNase***Description**

The `DNase` data frame has 176 rows and 3 columns of data obtained during development of an ELISA assay for the recombinant protein DNase in rat serum.

Usage

```
DNase
```

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

`Run` an ordered factor with levels `10 < ... < 3` indicating the assay run.

`conc` a numeric vector giving the known concentration of the protein.

`density` a numeric vector giving the measured optical density (dimensionless) in the assay. Duplicate optical density measurements were obtained.

Details

This dataset was originally part of package **nlme**, and that has methods (including for `[, as.data.frame, plot` and `print`) for its grouped-data classes.

```

euro

*Conversion Rates of Euro Currencies***Description**

Conversion rates between the various Euro currencies.

Usage

```
euro
euro.cross
```

Format

`euro` is a named vector of length 11, `euro.cross` a matrix of size 11 by 11, with `dimnames`.

Details

The data set `euro` contains the value of 1 Euro in all currencies participating in the European monetary union (Austrian Schilling ATS, Belgian Franc BEF, German Mark DEM, Spanish Peseta ESP, Finnish Markka FIM, French Franc FRF, Irish Punt IEP, Italian Lira ITL, Luxembourg Franc LUF, Dutch Guilder NLG and Portuguese Escudo PTE). These conversion rates were fixed by the European Union on December 31, 1998. To convert old prices to Euro prices, divide by the respective rate and round to 2 digits.

The data set `euro.cross` contains conversion rates between the various Euro currencies, i.e., the result of `outer(1 / euro, euro)`.

Examples

```

cbind(euro)

## These relations hold:
euro == signif(euro, 6) # [6 digit precision in Euro's definition]
all(euro.cross == outer(1/euro, euro))

## Convert 20 Euro to Belgian Franc
20 * euro["BEF"]
## Convert 20 Austrian Schilling to Euro
20 / euro["ATS"]
## Convert 20 Spanish Pesetas to Italian Lira

```

```

20 * euro.cross["ESP", "ITL"]

require(graphics)
dotchart(euro,
  main = "euro data: 1 Euro in currency unit")
dotchart(1/euro,
  main = "euro data: 1 currency unit in Euros")
dotchart(log(euro, 10),
  main = "euro data: log10(1 Euro in currency unit)")

```

eurodist

*Distances Between European Cities and Between US Cities***Description**

The eurodist gives the road distances (in km) between 21 cities in Europe. The data are taken from a table in *The Cambridge Encyclopaedia*.

UScitiesD gives “straight line” distances between 10 cities in the US.

Usage

```

eurodist
UScitiesD

```

Format

dist objects based on 21 and 10 objects, respectively. (You must have the **stats** package loaded to have the methods for this kind of object available).

Source

Crystal D (ed.) (1990). *The Cambridge Encyclopaedia*. Cambridge University Press, Cambridge. ISBN 0521395283.

The US cities distances were provided by Pierre Legendre.

EuStockMarkets

*Daily Closing Prices of Major European Stock Indices, 1991–1998***Description**

Contains the daily closing prices of major European stock indices: Germany DAX (Ibis), Switzerland SMI, France CAC, and UK FTSE. The data are sampled in business time, i.e., weekends and holidays are omitted.

Usage

```

EuStockMarkets

```

Format

A multivariate time series with 1860 observations on 4 variables. The object is of class "mts".

Source

The data were kindly provided by Erste Bank AG, Vienna, Austria.

faithful

Old Faithful Geyser Data

Description

Waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

Usage

```
faithful
```

Format

A data frame with 272 observations on 2 variables.

[,1]	eruptions	numeric	Eruption time in mins
[,2]	waiting	numeric	Waiting time to next eruption (in mins)

Details

A closer look at `faithful$eruptions` reveals that these are heavily rounded times originally in seconds, where multiples of 5 are more frequent than expected under non-human measurement. For a better version of the eruption times, see the example below.

There are many versions of this dataset around: Azzalini and Bowman (1990) use a more complete version.

Source

W. Härdle.

References

freeny

Freeny's Revenue Data

Description

Freeny's data on quarterly revenue and explanatory variables.

Usage

```
freeny
freeny.x
freeny.y
```

Format

There are three 'freeny' data sets.

`freeny.y` is a time series with 39 observations on quarterly revenue from (1962,2Q) to (1971,4Q).

`freeny.x` is a matrix of explanatory variables. The columns are `freeny.y` lagged 1 quarter, price index, income level, and market potential.

Finally, `freeny` is a data frame with variables `y`, `lag.quarterly.revenue`, `price.index`, `income.level`, and `market.potential` obtained from the above two data objects.

Source

```

```

mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)

```

gait

Hip and Knee Angle while Walking

Description

Hip and knee angle (in degrees) through a 20 point movement cycle for 39 boys.

Usage

```
gait
```

Format

A 3-dimensional array with dimensions `c(20, 39, 2)` giving the "Hip Angle" and "Knee Angle" (in degrees) for 39 repetitions of a 20 point gait cycle (over standardized gait times).

Details

The named components of `dimnames(gait)` are as follows:

Time `seq(from = 0.025, to = 0.975, by = 0.05)`

Subject `"boy1", "boy2", ..., "boy39"`

Variable `"Hip Angle" and "Knee Angle"`

Note

This is the version of the data as in the **fda** package and corresponding textbooks, but with named dimensions. One record appears to be duplicated from the original paper (Olshen, Biden, Wyatt, and Sutherland 1989), which analyses a sample of 38 boys. The `gait` dataset has 39 boys but `boy19` and `boy26` have identical measurements.

options(op)

```

HairEyeColor

Hair and Eye Color of Statistics Students

Description

Distribution of hair and eye color and sex in 592 statistics students.

Usage

```
HairEyeColor
```

Format

A 3-dimensional array resulting from cross-tabulating 592 observations on 3 variables. The variables and their levels are as follows:

No	Name	Levels
1	Hair	Black, Brown, Red, Blond
2	Eye	Brown, Blue, Hazel, Green
3	Sex	Male, Female

Details

The Hair $\times$ Eye table comes from a survey of students at the University of Delaware reported by Snee (1974). The split by Sex was added by Friendly (1992) for didactic purposes.

This data set is useful for illustrating various techniques for the analysis of contingency tables, such as the standard chi-squared test or, more generally, log-linear modelling, and graphical methods such as mosaic plots, sieve diagrams or association plots.

Source

<http://www.datavis.ca/sas/vcd/catdata/haireye.sas>

Snee (1974) gives the two-way table aggregated over Sex. The Sex split of the ‘Brown hair, Brown eye’ cell was changed to agree with that used by Friendly (2000).

Indometh

Pharmacokinetics of Indomethacin

Description

The Indometh data frame has 66 rows and 3 columns of data on the pharmacokinetics of indometacin (or, older spelling, 'indomethacin').

Usage

```
Indometh
```

Format

An object of class `c("nfGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

`Subject` an ordered factor containing the subject codes. The ordering is according to increasing maximum response.

`time` a numeric vector of times at which blood samples were drawn (hr).

`conc` a numeric vector of plasma concentrations of indometacin (mcg/ml).

Details

Each of the six subjects was given an intravenous injection of indometacin.

This dataset was originally part of package **nlme** (Pinheiro and Bates 2000, Appendix A.12), and that has methods (including for `[, as.data.frame, plot` and `print`) for its grouped-data classes.

iris	<i>Edgar Anderson’s Iris Data</i>
------	-----------------------------------

Description

This famous (Fisher’s or Anderson’s) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are *Iris setosa*, *versicolor*, and *virginica*.

Usage

```
iris
iris3
```

Format

iris is a data frame with 150 cases (rows) and 5 variables (columns) named Sepal.Length, Sepal.Width, Petal.Length, Petal.Width, and Species.

iris3 gives the same data arranged as a 3-dimensional array of size 50 by 4 by 3, as once provided by S-PLUS. The first dimension gives the case number within the species subsample, the second the measurements with names Sepal L., Sepal W., Petal L., and Petal W., and the third the species.

Source

Fisher (1936).

The data were collected by Anderson (1935).

References

LakeHuron*Level of Lake Huron 1875–1972*

Description

Annual measurements of the level, in feet, of Lake Huron 1875–1972.

Usage

LakeHuron

Format

A time series of length 98.

Source

Brockwell PJ, Davis RA (1991). *Time Series: Theory and Methods*, series Springer Series in Statistics, Second edition. Springer, New York. ISBN 9780387974293. Page 555.

Brockwell PJ, Davis RA (1996). *Introduction to Time Series and Forecasting*, series Springer Texts in Statistics. Springer, New York. doi:10.1007/9781475725261. Sections 5.1 and 7.6.

lh*Luteinizing Hormone in Blood Samples*

Description

A regular time series giving the luteinizing hormone in blood samples at 10 mins intervals from a human female, 48 samples.

Usage

lh

Source

Diggle PJ (1991). *Time Series: A Biostatistical Introduction*. Clarendon Press, Oxford. ISBN 0198522266. Table A.1, series 3.

LifeCycleSavings *Intercountry Life-Cycle Savings Data*

Description

Data on the savings ratio 1960–1970.

Usage

LifeCycleSavings

Format

A data frame with 50 observations on 5 variables.

[,1]	sr	numeric	aggregate personal savings
[,2]	pop15	numeric	% of population under 15
[,3]	pop75	numeric	% of population over 75
[,4]	dpi	numeric	real per-capita disposable income
[,5]	ddpi	numeric	% growth rate of dpi

Details

Under the life-cycle savings hypothesis as developed by Franco Modigliani, the savings ratio (aggregate personal saving divided by disposable income) is explained by per-capita disposable income, the percentage rate of change in per-capita disposable income, and two demographic variables: the percentage of population less than 15 years old and the percentage of the population over 75 years old. The data are averaged over the decade 1960–1970 to remove the business cycle or other short-term fluctuations.

Note

The dataset in R < 4.6.0 had a typo in the row name "Guatemala". The examples show how to recreate that version.

Source

The data were obtained from Belsley, Kuh, and Welsch (1980, pp. 41–42). They in turn obtained the data from Sterling (1977).

References

Belsley DA, Kuh E, Welsch RE (1980). *Regression Diagnostics: Identifying Influential Data and Sources of Collinearity*. John Wiley & Sons. doi:10.1002/0471725153.

```

Loblolly

Growth of Loblolly Pine Trees

Description

The `Loblolly` data frame has 84 rows and 3 columns of records of the growth of Loblolly pine trees.

Usage

```
Loblolly
```

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

`height` a numeric vector of tree heights (ft).

`age` a numeric vector of tree ages (yr).

`Seed` an ordered factor indicating the seed source for the tree. The ordering is according to increasing maximum height.

Details

This dataset was originally part of package **nlme**, and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

lines(age, predict(fml, list(age = age)))
```

longley

*Longley's Economic Regression Data***Description**

A macroeconomic data set which provides a well-known example for a highly collinear regression.

Usage

```
longley
```

Format

A data frame with 7 economical variables, observed yearly from 1947 to 1962 ($n = 16$).

GNP.deflator GNP implicit price deflator (1954 = 100)

GNP Gross National Product.

Unemployed number of unemployed.

Armed.Forces number of people in the armed forces.

Population 'noninstitutionalized' population ≥ 14 years of age.

Year the year (time).

Employed number of people employed.

The regression `lm(Employed ~ .)` is known to be highly collinear.

Source

morley

Michelson Speed of Light Data

Description

A classical data of Michelson (but not this one with Morley) on measurements done in 1879 on the speed of light. The data consists of five experiments, each consisting of 20 consecutive ‘runs’. The response is the speed of light measurement, suitably coded (km/sec, with 299000 subtracted).

Usage

morley

Format

A data frame with 100 observations on the following 3 variables.

Expt The experiment number, from 1 to 5.

Run The run number within each experiment.

Speed Speed-of-light measurement.

Details

The data is here viewed as a randomized block experiment with ‘experiment’ and ‘run’ as the factors. ‘run’ may also be considered a quantitative variate to account for linear (or polynomial) changes in the measurement over the course of a single experiment.

Note

This is the same dataset as `micelson` in package **MASS**.

Source

Michelson AA (1882). “Experimental Determination of the Velocity of Light: Made at the U.S. Naval Academy, Annapolis.” *Astronomical Papers*, **1**, 109–145. Provided by the SAO/NASA Astrophysics Data System, <https://ui.adsabs.harvard.edu/abs/1882USNAO...1..109M>.
(See Table 24.)

Stigler SM (1977). “Do Robust Estimators Work with Real Data?” *The Annals of Statistics*, **5**(6), 1055–1098. doi:10.1214/aos/1176343997.
(See Table 6.)

Weekes AJ (1986). *A Genstat Primer*. Hodder Arnold. ISBN 978-0713136074.

Examples

```
require(stats); require(graphics)
micelson <- transform(morley,
                      Expt = factor(Expt), Run = factor(Run))
xtabs(~ Expt + Run, data = micelson) # 5 x 20 balanced (two-way)
plot(Speed ~ Expt, data = micelson,
     main = "Speed of Light Data", xlab = "Experiment No.")
fm <- aov(Speed ~ Run + Expt, data = micelson)
summary(fm)
fm0 <- update(fm, . ~ . - Run)
anova(fm0, fm)
```

mtcars

Motor Trend Car Road Tests

Description

The data was extracted from the 1974 *Motor Trend* US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

Usage

```
mtcars
```

Format

A data frame with 32 observations on 11 (numeric) variables.

[, 1]	mpg	Miles/(US) gallon
[, 2]	cyl	Number of cylinders
[, 3]	disp	Displacement (cu.in.)
[, 4]	hp	Gross horsepower
[, 5]	drat	Rear axle ratio
[, 6]	wt	Weight (1000 lbs)
[, 7]	qsec	1/4 mile time
[, 8]	vs	Engine (0 = V-shaped, 1 = straight)
[, 9]	am	Transmission (0 = automatic, 1 = manual)
[,10]	gear	Number of forward gears
[,11]	carb	Number of carburetors

Note

Henderson and Velleman (1981) comment in a footnote to Table 1: ‘Hocking [original transcriber]’s noncrucial coding of the Mazda’s rotary engine as a straight six-cylinder engine and the Porsche’s flat engine as a V engine, as well as the inclusion of the diesel Mercedes 240D, have been retained to enable direct comparisons to be made with previous analyses.’

```

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

```
npk
```

Format

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

occupationalStatus *Occupational Status of Fathers and their Sons*

Description

Cross-classification of a sample of British males according to each subject's occupational status and his father's occupational status.

Usage

```
occupationalStatus
```

Format

A [table](#) of counts, with classifying factors `origin` (father's occupational status; levels 1 : 8) and `destination` (son's occupational status; levels 1 : 8).

Source

Goodman LA (1979). “Simple Models for the Analysis of Association in Cross-Classifications Having Ordered Categories.” *Journal of the American Statistical Association*, **74**(367), 537–552. doi:[10.1080/01621459.1979.10481650](https://doi.org/10.1080/01621459.1979.10481650).

The data set has been in package **gnm** and been provided by the package authors.

Examples

```
require(stats); require(graphics)

plot(occupationalStatus)

## Fit a uniform association model separating diagonal effects
Diag <- as.factor(diag(1:8))
Rscore <- scale(as.numeric(row(occupationalStatus)), scale = FALSE)

summary(modUnif)
plot(modUnif) # 4 plots, with warning about h_ii ~= 1
```

Orange

Growth of Orange Trees

Description

The Orange data frame has 35 rows and 3 columns of records of the growth of orange trees.

Usage

Orange

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

Tree an ordered factor indicating the tree on which the measurement is made. The ordering is according to increasing maximum diameter.

age a numeric vector giving the age of the tree (days since 1968/12/31)

circumference a numeric vector of trunk circumferences (mm). This is probably “circumference at breast height”, a standard measurement in forestry.

Details

This dataset was originally part of package **nlme**, and that has methods (including for `[, as.data.frame, plot` and `print`) for its grouped-data classes.

Pinheiro J, Bates DM (2000). *Mixed-Effects Models in S and S-PLUS*, series Statistics and Computing. Springer New York. ISBN 9780387989570.

Examples

```
require(stats); require(graphics)
coplot(circumference ~ age | Tree, data = Orange, show.given = FALSE)
fml <- nls(circumference ~ SSlogis(age, Asym, xmid, scal),
          data = Orange, subset = Tree == 3)
plot(circumference ~ age, data = Orange, subset = Tree == 3,
     xlab = "Tree age (days since 1968/12/31)",
     ylab = "Tree circumference (mm)", las = 1,
     main = "Orange tree data and fitted model (Tree 3 only)")
age <- seq(0, 1600, length.out = 101)
lines(age, predict(fml, list(age = age)))
```

OrchardSprays	Potency of Orchard Sprays
---------------	---------------------------

Description

An experiment was conducted to assess the potency of various constituents of orchard sprays in repelling honeybees, using a Latin square design.

Usage

```
OrchardSprays
```

Format

A data frame with 64 observations on 4 variables.

[,1]	rowpos	numeric	Row of the design
[,2]	colpos	numeric	Column of the design
[,3]	treatment	factor	Treatment level
[,4]	decrease	numeric	Response

Details

Individual cells of dry comb were filled with measured amounts of lime sulphur emulsion in sucrose solution. Seven different concentrations of lime sulphur ranging from a concentration of 1/100 to 1/1,562,500 in successive factors of 1/5 were used as well as a solution containing no lime sulphur. The responses for the different solutions were obtained by releasing 100 bees into the chamber for two hours, and then measuring the decrease in volume of the solutions in the various cells.

An 8 × 8 Latin square design was used and the treatments were coded as follows:

- A highest level of lime sulphur
- B next highest level of lime sulphur

```

.
.
.
G  lowest level of lime sulphur
H  no lime sulphur

```

penguins

Measurements of Penguins near Palmer Station, Antarctica

Description

Data on adult penguins covering three species found on three islands in the Palmer Archipelago, Antarctica, including their size (flipper length, body mass, bill dimensions), and sex.

The columns of `penguins` are a subset of the more extensive `penguins_raw` data frame, which includes nesting observations and blood isotope data. There are differences in the column names and data types. See the ‘Format’ section for details.

Usage

```

penguins
penguins_raw

```

Format

`penguins` is a data frame with 344 rows and 8 variables:

```

species factor, with levels Adelie, Chinstrap, and Gentoo
island  factor, with levels Biscoe, Dream, and Torgersen
bill_len numeric, bill length (millimeters)
bill_dep numeric, bill depth (millimeters)
flipper_len integer, flipper length (millimeters)
body_mass integer, body mass (grams)
sex     factor, with levels female and male
year    integer, study year: 2007, 2008, or 2009

```

`penguins_raw` is a data frame with 344 rows and 17 variables. 8 columns correspond to columns in `penguins`, though with different variable names and/or classes:

Species character

Island character

Culmen Length (mm) numeric, bill length

Culmen Depth (mm) numeric, bill depth

Flipper Length (mm) numeric, flipper length

Body Mass (g) numeric, body mass

Sex character

Date Egg [Date](#), when study nest observed with 1 egg. The year component is the year column in `penguins`

There are 9 further columns in `penguins_raw`:

studyName character, expedition during which the data was collected

Sample Number numeric, continuous numbering sequence for each sample

Region character, the region of Palmer LTER sampling grid

Stage character, denoting reproductive stage at sampling

Individual ID character, unique ID for each individual in dataset

Clutch Completion character, if the study nest was observed with a full clutch, i.e., 2 eggs

Delta 15 N (o/oo) numeric, the ratio of stable isotopes 15N:14N

Delta 13 C (o/oo) numeric, the ratio of stable isotopes 13C:12C

Comments character, additional relevant information

Details

Gorman, Williams, and Fraser (2014) used the data to study sex dimorphism separately for the three species.

Horst, Presmanes Hill, and Gorman (2022) popularized the data as an illustration for different statistical methods, as an alternative to the [iris](#) data.

Kaye, Turner, Gorman, Horst, and Presmanes Hill (2025) provide the scripts used to create these data sets from the original source data, and a notebook reproducing results from Gorman et al. (2014).

Note

These data sets are also available in the [palmerpenguins](#) package. See the [package website](#) for further details and resources.

The `penguins` data has some shorter variable names than the `palmerpenguins` version, for compact code and data display.

Source

Adélie penguins: Palmer Station Antarctica LTER, Gorman KB (2020). “Structural size measurements and isotopic signatures of foraging among adult male and female Adélie penguins (*Pygoscelis adeliae*) nesting along the Palmer Archipelago near Palmer Station, 2007-2009.” [doi:10.6073/pasta/98b16d7d563f265cb52372c8ca99e60f](https://doi.org/10.6073/pasta/98b16d7d563f265cb52372c8ca99e60f).

Gentoo penguins: Palmer Station Antarctica LTER, Gorman KB (2020). “Structural Size Measurements and Isotopic Signatures of Foraging among Adult Male and Female Gentoo Penguin (*Pygoscelis papua*) Nesting along the Palmer Archipelago near Palmer Station, 2007-2009.” doi:10.6073/pasta/7fca67fb28d56ee2ffa3d9370ebda689.

Chinstrap penguins: Palmer Station Antarctica LTER, Gorman KB (2020). “Structural Size Measurements and Isotopic Signatures of Foraging among Adult Male and Female Chinstrap Penguin (*Pygoscelis antarctica*) Nesting along the Palmer Archipelago near Palmer Station, 2007-2009.” doi:10.6073/pasta/c14dfcfada8ea13a17536e73eb6fbe9e.

The title naming convention for the source for the Gentoo and Chinstrap data is that same as for Adélie penguins.

Puromycin

Reaction Velocity of an Enzymatic Reaction

Description

The `Puromycin` data frame has 23 rows and 3 columns of the reaction velocity versus substrate concentration in an enzymatic reaction involving untreated cells or cells treated with Puromycin.

Usage

```
Puromycin
```

Format

This data frame contains the following columns:

```
conc a numeric vector of substrate concentrations (ppm)
rate a numeric vector of instantaneous reaction rates (counts/min/min)
state a factor with levels 'treated' and 'untreated'
```

Details

Data on the velocity of an enzymatic reaction were obtained by Treloar (1974). The number of counts per minute of radioactive product from the reaction was measured as a function of substrate concentration in parts per million (ppm) and from these counts the initial rate (or velocity) of the reaction was calculated (counts/min/min). The experiment was conducted once with the enzyme treated with Puromycin, and once with the enzyme untreated.

           algorithm = "plinear")
```

quakes

Locations of Earthquakes off Fiji

Description

The data set give the locations of 1000 seismic events of MB > 4.0. The events occurred in a cube near Fiji since 1964.

Usage

quakes

Format

A data frame with 1000 observations on 5 variables.

[,1]	lat	numeric	Latitude of event
[,2]	long	numeric	Longitude
[,3]	depth	numeric	Depth (km)
[,4]	mag	numeric	Richter Magnitude
[,5]	stations	numeric	Number of stations reporting

Details

There are two clear planes of seismic activity. One is a major plate junction; the other is the Tonga trench off New Zealand. These data constitute a subsample from a larger dataset of containing 5000 observations.

Source

This is one of the Harvard PRIM-H project data sets. They in turn obtained it from Dr. John Woodhouse, Dept. of Geophysics, Harvard University.

Examples

```
require(graphics)
pairs(quakes, main = "Fiji Earthquakes, N = 1000", cex.main = 1.2, pch = ".")
```

randu

Random Numbers from Congruential Generator RANDU

Description

400 triples of successive random numbers were taken from the VAX FORTRAN function RANDU running under VMS 1.5.

Usage

```
randu
```

Format

A data frame with 400 observations on 3 variables named x, y and z which give the first, second and third random number in the triple.

Details

In three dimensional displays it is evident that the triples fall on 15 parallel planes in 3-space. This can be shown theoretically to be true for all triples from the RANDU generator.

These particular 400 triples start 5 apart in the sequence, that is they are $((U[5i+1], U[5i+2], U[5i+3]), i = 0, \dots, 399)$, and they are rounded to 6 decimal places.

Under VMS versions 2.0 and higher, this problem has been fixed.

Source

David Donoho

Examples

```
## We could re-generate the dataset by the following R code
seed <- as.double(1)
RANDU <- function() {
  seed <- ((2^16 + 3) * seed) %% (2^31)
  seed / (2^31)
}
myrandu <- matrix(NA_real_, 400, 3, dimnames = list(NULL, c("x", "y", "z")))
for(i in 1:400) {
  U <- c(RANDU(), RANDU(), RANDU(), RANDU(), RANDU())
  myrandu[i,] <- round(U[1:3], 6)
}
stopifnot(all.equal(randu, as.data.frame(myrandu), tolerance = 1e-5))
```

rivers

Lengths of Major North American Rivers

Description

This data set gives the lengths (in miles) of 141 “major” rivers in North America, as compiled by the US Geological Survey.

Usage

```
rivers
```

Format

A vector containing 141 observations.

Source

World Almanac and Book of Facts, 1975, page 406.

McNeil D (1977). *Interactive Data Analysis: A Practical Primer*. John Wiley & Sons. ISBN 978-0471026310.

rock

Measurements on Petroleum Rock Samples

Description

Measurements on 48 rock samples from a petroleum reservoir.

Usage

```
rock
```

Format

A data frame with 48 rows and 4 numeric columns.

[,1]	area	area of pores space, in pixels out of 256 by 256
[,2]	peri	perimeter in pixels
[,3]	shape	perimeter/sqrt(area)
[,4]	perm	permeability in millidarcies

Details

Twelve core samples from petroleum reservoirs were sampled by 4 cross-sections. Each core sample was measured for permeability, and each cross-section has total area of pores, total perimeter of pores, and shape.

Source

Data from BP Research, image analysis by Ronit Katz, U. Oxford.

sleep

Student's Sleep Data

Description

Data which show the effect of two soporific drugs (increase in hours of sleep compared to control) on 10 patients.

Usage

```
sleep
```

Format

A data frame with 20 observations on 3 variables.

[, 1]	extra	numeric	increase in hours of sleep
[, 2]	group	factor	drug given
[, 3]	ID	factor	patient ID

Details

The group variable name may be misleading about the data: They represent measurements on 10 persons, not in groups.

```

stackloss

Brownlee's Stack Loss Plant Data

Description

Operational data of a plant for the oxidation of ammonia to nitric acid.

Usage

```
stackloss

stack.x
stack.loss
```

Format

stackloss is a data frame with 21 observations on 4 variables.

[,1]	Air Flow	Flow of cooling air
[,2]	Water Temp	Cooling Water Inlet Temperature
[,3]	Acid Conc.	Concentration of acid [per 1000, minus 500]

```
[,4]  stack.loss  Stack loss
```

For historical compatibility with S-PLUS, the data sets `stack.x`, a matrix with the first three (independent) variables of the data frame, and `stack.loss`, the numeric vector giving the fourth (dependent) variable, are also provided.

Details

“Obtained from 21 days of operation of a plant for the oxidation of ammonia (NH₃) to nitric acid (HNO₃). The nitric oxides produced are absorbed in a countercurrent absorption tower”. (Brownlee, cited by Dodge, slightly reformatted by MM.)

`Air Flow` represents the rate of operation of the plant. `Water Temp` is the temperature of cooling water circulated through coils in the absorption tower. `Acid Conc.` is the concentration of the acid circulating, minus 50, times 10: that is, 89 corresponds to 58.9 per cent acid. `stack.loss` (the dependent variable) is 10 times the percentage of the ingoing ammonia to the plant that escapes from the absorption column unabsorbed; that is, an (inverse) measure of the over-all efficiency of the plant.

```

Details

R currently contains the following “state” data sets. Note that all data are arranged according to alphabetical order of the state names.

`state.abb` character vector of 2-letter abbreviations for the state names.

`state.area` numeric vector of state areas (in square miles).

`state.center` list with components named `x` and `y` giving the approximate geographic center of each state in negative longitude and latitude. Alaska and Hawaii are placed just off the West Coast. See ‘Examples’ on how to “correct”.

`state.division` `factor` giving state divisions (New England, Middle Atlantic, South Atlantic, East South Central, West South Central, East North Central, West North Central, Mountain, and Pacific).

`state.name` character vector giving the full state names.

`state.region` `factor` giving the region (Northeast, South, North Central, West) that each state belongs to.

`state.x77` matrix with 50 rows and 8 columns giving the following statistics in the respective columns.

Population population estimate as of July 1, 1975

Income per capita income (1974)

Illiteracy illiteracy (1970, percent of population)

Life Exp life expectancy in years (1969–71)

Murder murder and non-negligent manslaughter rate per 100,000 population (1976)

HS Grad percent high-school graduates (1970)

Frost mean number of days with minimum temperature below freezing (1931–1960) in capital or large city

Area land area in square miles

Note that a square mile is by definition exactly $(\text{cm}(1760 * 3 * 12) / 100 / 1000)^2 \text{ km}^2$, i.e., $2.589988110336 \text{ km}^2$.

```

sunspot.month

Monthly Sunspot Data, from 1749 to "Present"

Description

Monthly numbers of sunspots, as from the World Data Center, aka SIDC. `sunspot.month` is the version of the data that will occasionally be updated when new counts become available (or the numbers are recalibrated). Note that around 2014–2015 there has been an international effort to recalibrate the sunspots numbers; since R 4.5.0 (2025), the recalibrated series is used.

The version in (too long) use from 2014 to 2024 is provided as `sunspot.m2014` for historical and reproducibility reasons. For strict reproducibility, hence use that, or [sunspots](#) instead of `sunspot.month`.

Usage

```
sunspot.month
sunspot.m2014
```

Format

The univariate time series `sunspot.year`, `sunspot.m2014` and `sunspot.month` contain 289, 3177, and currently 3310 observations, respectively, where the latter will increase over time. The objects are of class `"ts"`.

Author(s)

R Core Team.

Source

WDC-SILSO, Solar Influences Data Analysis Center (SIDC), Royal Observatory of Belgium, Av. Circulaire, 3, B-1180 BRUSSELS Currently at <https://www.sidc.be/SILSO/datafiles>

From around 2015, expert astronomers decided to recalibrate historical sunspot numbers, see the 'References'. This is *not yet* visible in current `sunspot.month` but may well change by the next release of R.

See Also

`sunspot.month` is a more up-to-date and hence also longer version of `sunspots`; the latter runs until 1983 and is kept fixed (for reproducibility as example dataset).

Examples

```
require(stats); require(graphics)
## Compare the monthly series
plot (sunspot.month,
      main="sunspot.month & sunspots [package 'datasets']", col=2)
lines(sunspots) # -> clear recalibration (to *larger* values)
at. <- seq(1750, 2030, by=10)
atyr <- at.[at. %% 50 != 0] ##
Axis(time(sunspot.month), at = atyr, side = 1,
      tck= -1/100, padj = -1.5, cex.axis = 3/4)

## Now look at the difference :
all(tsp(sunspots) [c(1,3)] ==
    tsp(sunspot.month)[c(1,3)]) ## Start & Periodicity are the same
n1 <- length(sunspots)
table(eq <- sunspots == sunspot.m2014[1:n1]) #> 143 are different !
i <- which(!eq)
rug(time(eq)[i])
s1 <- sunspots[i] ; s2 <- sunspot.m2014[i]
cbind(i = i, time = time(sunspots)[i], sunspots = s1, ss.month = s2,
      perc.diff = round(100*2*abs(s1-s2)/(s1+s2), 1))

## How to recreate the "old" sunspot.month (R <= 3.0.3) := sunspot.month.0
.sunspot.diff <- cbind(
  i = c(1202L, 1256L, 1258L, 1301L, 1407L, 1429L, 1452L, 1455L,
        1663L, 2151L, 2329L, 2498L, 2594L, 2694L, 2819L),
  res10 = c(1L, 1L, 1L, -1L, -1L, -1L, 1L, -1L,
            1L, 1L, 1L, 1L, 1L, 20L, 1L))
ssm0 <- sunspot.m2014[1:2988]
with(as.data.frame(.sunspot.diff), ssm0[i] <- ssm0[i] - res10/10)
```

```
sunspot.month.0 <- ts(ssm0, start = 1749, frequency = 12)
stopifnot(length(sunspot.month.0) == 2988)
```

sunspot.year	<i>Yearly Sunspot Data, 1700–1988</i>
--------------	---------------------------------------

Description

Yearly numbers of sunspots from 1700 to 1988 (rounded to one digit).

Note that monthly numbers are available as [sunspot.month](#), though starting slightly later.

Usage

```
sunspot.year
```

Format

The univariate time series `sunspot.year` contains 289 observations, and is of class `"ts"`.

Source

Tong H (1996). *Non-Linear Time Series*. Clarendon Press, Oxford. ISBN 0198523009. Page 471.

See Also

For *monthly* sunspot numbers, see [sunspot.month](#) and [sunspots](#).

Regularly updated yearly sunspot numbers are available from WDC-SILSO, Royal Observatory of Belgium, at <https://www.sidc.be/SILSO/datafiles>

Examples

```
utils::str(sm <- sunspots) # the monthly version we keep unchanged
utils::str(sy <- sunspot.year)
## The common time interval
(t1 <- c(max(start(sm), start(sy)), 1)) # Jan 1749
(t2 <- c(min(end(sm)[1], end(sy)[1]), 12)) # Dec 1983 (will not be updated!)
s.m <- window(sm, start=t1, end=t2)
s.y <- window(sy, start=t1, end=t2[1])
stopifnot(length(s.y) * 12 == length(s.m),
          ## The yearly series *is* close to the averages of the monthly one:
          all.equal(s.y, aggregate(s.m, FUN = mean), tolerance = 0.0020))
## NOTE: Strangely, correctly weighting the number of days per month
## (using 28.25 for February) is *not* closer than the simple mean:
ndays <- c(31, 28.25, rep(c(31, 30, 31, 30, 31), 2))
all.equal(s.y, aggregate(s.m, FUN = mean)) # 0.0013
all.equal(s.y, aggregate(s.m, FUN = weighted.mean, w = ndays)) # 0.0017
```

`sunspots`*Monthly Sunspot Numbers, 1749–1983*

Description

Monthly mean relative sunspot numbers from 1749 to 1983. Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory.

Usage`sunspots`**Format**

A time series of monthly data from 1749 to 1983.

Source

Andrews DF, Herzberg AM (1985). *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. Springer, New York, NY. ISBN 9781461250982. doi:[10.1007/978-1461250982](https://doi.org/10.1007/978-1461250982).

See Also

`sunspot.month` has a longer (and a bit different) series, `sunspot.year` is a much shorter one. See there for getting more current sunspot numbers.

Examples

```
require(graphics)
plot(sunspots, main = "sunspots data", xlab = "Year",
     ylab = "Monthly sunspot numbers")
```

`swiss`*Swiss Fertility and Socioeconomic Indicators (1888) Data*

Description

Standardized fertility measure and socioeconomic indicators for each of 47 French-speaking provinces of Switzerland at about 1888.

Usage`swiss`

Format

A data frame with 47 observations on 6 variables, *each* of which is in percent, i.e., in $[0, 100]$.

[,1]	Fertility	I_g , ‘common standardized fertility measure’
[,2]	Agriculture	% of males involved in agriculture as occupation
[,3]	Examination	% draftees receiving highest mark on army examination
[,4]	Education	% education beyond primary school for draftees.
[,5]	Catholic	% ‘catholic’ (as opposed to ‘protestant’).
[,6]	Infant.Mortality	live births who live less than 1 year.

All variables but `Fertility` give proportions of the population.

Details

(paraphrasing Mosteller and Tukey):

Switzerland, in 1888, was entering a period known as the *demographic transition*; i.e., its fertility was beginning to fall from the high level typical of underdeveloped countries.

The data collected are for 47 French-speaking “provinces” at about 1888.

Here, all variables are scaled to $[0, 100]$, where in the original, all but `Catholic` were scaled to $[0, 1]$.

Note

Files for all 182 districts in 1888 and other years have been available at <https://oprdata.princeton.edu/archive/pefp/switz.aspx>. While the OPR (Office of Population Research at Princeton University) does not seem to provide these anymore, a html-simplified copy of the information page is at https://www.r-project.org/doc/reports/OPR_DataArchive_switz.html.

They state that variables `Examination` and `Education` are averages for 1887, 1888 and 1889.

      col = 3 + (swiss$Catholic > 50))
summary(lm(Fertility ~ . , data = swiss))
```

Theoph

*Pharmacokinetics of Theophylline***Description**

The Theoph data frame has 132 rows and 5 columns of data from an experiment on the pharmacokinetics of theophylline.

Usage

```
Theoph
```

Format

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

`Subject` an ordered factor with levels '1', ..., '12' identifying the subject on whom the observation was made. The ordering is by increasing maximum concentration of theophylline observed.

`Wt` weight of the subject (kg).

`Dose` dose of theophylline administered orally to the subject (mg/kg).

`Time` time since drug administration when the sample was drawn (hr).

`conc` theophylline concentration in the sample (mg/L).

Details

Boeckmann, Sheiner, and Beal (1994) report data from a study by Dr. Robert Upton of the kinetics of the anti-asthmatic drug theophylline. Twelve subjects were given oral doses of theophylline then serum concentrations were measured at 11 time points over the next 25 hours.

These data are analyzed in Davidian and Giltinan (1995, page 145 in section 5.5 and page 176 in section 6.6) and Pinheiro and Bates (2000) using a two-compartment open pharmacokinetic model, for which a self-starting model function, `SSfol`, is available.

This dataset was originally part of package **nlme** (Pinheiro and Bates 2000, Appendix A.29), and that has methods (including for `[], as.data.frame, plot` and `print`) for its grouped-data classes.

```

Titanic

Survival of passengers on the Titanic

Description

This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner ‘Titanic’, summarized according to economic status (class), sex, age and survival.

Usage

Titanic

Format

A 4-dimensional array resulting from cross-tabulating 2201 observations on 4 variables. The variables and their levels are as follows:

No	Name	Levels
1	Class	1st, 2nd, 3rd, Crew
2	Sex	Male, Female
3	Age	Child, Adult
4	Survived	No, Yes

Details

The sinking of the Titanic is a famous event, and new books are still being published about it. Many well-known facts—from the proportions of first-class passengers to the ‘women and children first’ policy, and the fact that that policy was not entirely successful in saving the women and children in the third class—are reflected in the survival rates for various classes of passenger.

These data were originally collected by the British Board of Trade in their investigation of the sinking. Note that there is not complete agreement among primary sources as to the exact numbers on board, rescued, or lost.

Due in particular to the very successful film ‘Titanic’, the last years saw a rise in public interest in the Titanic. Very detailed data about the passengers is now available on the Internet, at sites such as *Encyclopedia Titanica* (<https://www.encyclopedia-titanica.org/>).

Source

Dawson RJM (1995). “The “Unusual Episode” Data Revisited.” *Journal of Statistics Education*, **3**(3). doi:10.1080/10691898.1995.11910499..

The source provides a data set recording class, sex, age, and survival status for each person on board of the Titanic, and is based on data originally collected by the British Board of Trade and reprinted in:

British Government (1990). *Report on the Loss of the SS Titanic*. Allan Sutton Publishing, Gloucester, UK. ISBN 978-0862997236.

Examples

```
require(graphics)
mosaicplot(Titanic, main = "Survival on the Titanic")
## Higher survival rates in children?
apply(Titanic, c(3, 4), sum)
## Higher survival rates in females?
apply(Titanic, c(2, 4), sum)
## Use loglm() in package 'MASS' for further analysis ...
```

ToothGrowth

The Effect of Vitamin C on Tooth Growth in Guinea Pigs

Description

The response is the length of odontoblasts (cells responsible for tooth growth) in 60 guinea pigs. Each animal received one of three dose levels of vitamin C (0.5, 1, and 2 mg/day) by one of two delivery methods, orange juice or ascorbic acid (a form of vitamin C and coded as VC).

Usage

ToothGrowth

Format

A data frame with 60 observations on 3 variables.

[,1]	len	numeric	Tooth length
[,2]	supp	factor	Supplement type (VC or OJ).
[,3]	dose	numeric	Dose in milligrams/day

Source

Bliss CI (1952). *The Statistics of Bioassay*. Academic Press, New York, NY. ISBN 9781483256627.

```
require(graphics)
coplot(len ~ dose | supp, data = ToothGrowth, panel = panel.smooth,
       xlab = "ToothGrowth data: length vs dose, given type of supplement")
```

treering	<i>Yearly Tree-Ring Data, -6000–1979</i>
----------	--

Description

Contains normalized tree-ring widths in dimensionless units.

Usage

```
treering
```

Format

A univariate time series with 7980 observations. The object is of class "`ts`".

Each tree ring corresponds to one year.

Details

The data were recorded by Donald A. Graybill, 1980, from Gt Basin Bristlecone Pine 2805M, 3726-11810 in Methuselah Walk, California.

Source

trees	<i>Diameter, Height and Volume for Black Cherry Trees</i>
-------	---

Description

This data set provides measurements of the diameter, height and volume of timber in 31 felled black cherry trees. Note that the diameter (in inches) is erroneously labelled Girth in the data. It is measured at 4 ft 6 in above the ground.

Usage

```
trees
```

Format

A data frame with 31 observations on 3 variables.

[,1]	Girth	numeric	Tree diameter (rather than girth, actually) in inches
[,2]	Height	numeric	Height in ft
[,3]	Volume	numeric	Volume of timber in cubic ft

step(fm2)
## i.e., Volume ~ c * Height * Girth^2 seems reasonable
```

UCBAdmissions

Student Admissions at UC Berkeley

Description

Aggregate data on applicants to graduate school at Berkeley for the six largest departments in 1973 classified by admission and sex.

Usage

```
UCBAdmissions
```

Format

A 3-dimensional array resulting from cross-tabulating 4526 observations on 3 variables. The variables and their levels are as follows:

No	Name	Levels
1	Admit	Admitted, Rejected
2	Gender	Male, Female

3 Dept A, B, C, D, E, F

Details

This data set is frequently used for illustrating Simpson's paradox, see Bickel, Hammel, and O'Connell (1975). At issue is whether the data show evidence of sex bias in admission practices. There were 2691 male applicants, of whom 1198 (44.5%) were admitted, compared with 1835 female applicants of whom 557 (30.4%) were admitted. This gives a sample odds ratio of 1.83, indicating that males were almost twice as likely to be admitted. In fact, graphical methods (as in the example below) or log-linear modelling show that the apparent association between admission and sex stems from differences in the tendency of males and females to apply to the individual departments (females used to apply *more* to departments with higher rejection rates).

This data set can also be used for illustrating methods for graphical display of categorical data, such as the general-purpose [mosaicplot](#) or the [fourfoldplot](#) for 2-by-2-by-*k* tables.

        outer = TRUE, cex = 1.5)
par(opar)
```

UKDriverDeaths

Road Casualties in Great Britain 1969–84

Description

UKDriverDeaths is a time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983. The effects of this intervention were analyzed by Harvey and Durbin (1986).

Seatbelts is more information on the same problem.

Usage

```
UKDriverDeaths
Seatbelts
```

Format

Seatbelts is a multiple time series, with columns

DriversKilled car drivers killed.

drivers same as UKDriverDeaths.

front front-seat passengers killed or seriously injured.

rear rear-seat passengers killed or seriously injured.

kms distance driven.

PetrolPrice petrol price.

VanKilled number of van ('light goods vehicle') drivers killed.

law 0/1: was the law in effect that month?

        lty = c(1, 3, 2, 2), col = c("black", "red", "blue", "blue"))

## now see the effect of the explanatory variables
X <- Seatbelts[, c("kms", "PetrolPrice", "law")]
X[, 1] <- log10(X[, 1]) - 4
arima(log10(Seatbelts[, "drivers"]), c(1, 0, 0),
      seasonal = list(order = c(1, 0, 0)), xreg = X)
```

UKgas

UK Quarterly Gas Consumption

Description

Quarterly UK gas consumption from 1960Q1 to 1986Q4, in millions of therms.

Usage

UKgas

Format

A quarterly time series of length 108.

Source

Durbin J, Koopman SJ (2001). *Time Series Analysis by State Space Methods*. Oxford University Press. ISBN 0198523548.

Data was available from the book website, now archived at <https://web.archive.org/web/20020304222057/http://www.ssfpack.com/dkbook/>.

Examples

```
## maybe str(UKgas) ; plot(UKgas) ...
```

UKLungDeaths

Monthly Deaths from Lung Diseases in the UK

Description

Three time series giving the monthly deaths from bronchitis, emphysema and asthma in the UK, 1974–1979, both sexes (ldeaths), males (mdeaths) and females (fdeaths).

Usage

```
ldeaths
fdeaths
mdeaths
```

Source

Diggle PJ (1991). *Time Series: A Biostatistical Introduction*. Clarendon Press, Oxford. ISBN 0198522266. Table A.3.

Examples

```
require(stats); require(graphics) # for time
plot(ldeaths)
plot(mdeaths, fdeaths)
## Better labels:
yr <- floor(tt <- time(mdeaths))
plot(mdeaths, fdeaths,
      xy.labels = paste(month.abb[12*(tt - yr)], yr-1900, sep = "'"))
```

USAccDeaths

*Accidental Deaths in the US 1973–1978***Description**

A time series giving the monthly totals of accidental deaths in the USA. The values for the first six months of 1979 are 7798 7406 8363 8460 9217 9316.

Usage

```
USAccDeaths
```

Source

Brockwell PJ, Davis RA (1991). *Time Series: Theory and Methods*, series Springer Series in Statistics, Second edition. Springer, New York. ISBN 9780387974293.

USArrests

*Violent Crime Rates by US State***Description**

This data set contains statistics, in arrests per 100,000 residents for assault, murder, and rape in each of the 50 US states in 1973. Also given is the percent of the population living in urban areas.

Usage

```
USArrests
```

Format

A data frame with 50 observations on 4 variables.

[,1]	Murder	numeric	Murder arrests (per 100,000)
[,2]	Assault	numeric	Assault arrests (per 100,000)
[,3]	UrbanPop	numeric	Percent urban population
[,4]	Rape	numeric	Rape arrests (per 100,000)

Note

USArrests contains the data as in McNeil's monograph. For the UrbanPop percentages, a review of the table (No. 21) in the Statistical Abstracts 1975 reveals a transcription error for Maryland (and that McNeil used the same "round to even" rule that R's `round()` uses), as found by Daniel S Coven (Arizona).

See the example below on how to correct the error and improve accuracy for the '<n>.5' percentages.

Source

World Almanac and Book of facts 1975. (Crime rates).

Statistical Abstracts of the United States 1975, p.20, (Urban rates), possibly available as <https://books.google.ch/books?id=z19qAAAAMAAJ&pg=PA20>.

The `state` data sets.

Examples

```
summary(USArrests)

require(graphics)
pairs(USArrests, panel = panel.smooth, main = "USArrests data")

## Difference between 'USArrests' and its correction
USArrests["Maryland", "UrbanPop"] # 67 -- the transcription error
UA.C <- USArrests
UA.C["Maryland", "UrbanPop"] <- 76.6

## also +/- 0.5 to restore the original <n>.5 percentages
s5u <- c("Colorado", "Florida", "Mississippi", "Wyoming")
s5d <- c("Nebraska", "Pennsylvania")
UA.C[s5u, "UrbanPop"] <- UA.C[s5u, "UrbanPop"] + 0.5
UA.C[s5d, "UrbanPop"] <- UA.C[s5d, "UrbanPop"] - 0.5

## ==> UA.C is now a *C*orrected version of USArrests
```

USJudgeRatings

Lawyers' Ratings of State Judges in the US Superior Court

Description

Lawyers' ratings of state judges in the US Superior Court.

Usage

```
USJudgeRatings
```

Format

A data frame containing 43 observations on 12 numeric variables.

[,1]	CONT	Number of contacts of lawyer with judge.
[,2]	INTG	Judicial integrity.
[,3]	DMNR	Demeanor.
[,4]	DILG	Diligence.
[,5]	CFMG	Case flow managing.
[,6]	DECI	Prompt decisions.
[,7]	PREP	Preparation for trial.
[,8]	FAMI	Familiarity with law.
[,9]	ORAL	Sound oral rulings.
[,10]	WRIT	Sound written rulings.
[,11]	PHYS	Physical ability.
[,12]	RTEN	Worthy of retention.

Source

New Haven Register, 14 January, 1977 (from John Hartigan).

Examples

```
require(graphics)
pairs(USJudgeRatings, main = "USJudgeRatings data")
```

USPersonalExpenditure
Personal Expenditure Data

Description

This data set consists of United States personal expenditures (in billions of dollars) in the categories; food and tobacco, household operation, medical and health, personal care, and private education for the years 1940, 1945, 1950, 1955 and 1960.

Usage

```
USPersonalExpenditure
```

Format

A matrix with 5 rows and 5 columns.

Source

The World Almanac and Book of Facts, 1962, page 756.

References

USPersonalExpenditure
medpolish(log10(USPersonalExpenditure))
```

 uspop

Populations Recorded by the US Census

Description

The population of the United States (in millions) at the 19 decennial censuses from 1790 to 1970.

Usage

```
uspop
```

Format

A time series of 19 values.

Source

McNeil D (1977). *Interactive Data Analysis: A Practical Primer*. John Wiley & Sons. ISBN 978-0471026310.

Examples

```
require(graphics)
plot(uspop, log = "y", main = "uspop data", xlab = "Year",
     ylab = "U.S. Population (millions)")
```

 VADeaths

Death Rates in Virginia (1940)

Description

Death rates per 1000 in Virginia in 1940.

Usage

```
VADeaths
```

Format

A matrix with 5 rows and 4 columns.

Details

The death rates are measured per 1000 population per year. They are cross-classified by age group (rows) and population group (columns). The age groups are: 50–54, 55–59, 60–64, 65–69, 70–74 and the population groups are Rural/Male, Rural/Female, Urban/Male and Urban/Female.

This provides a rather nice 3-way analysis of variance example.

d.VAD <- data.frame(
  Drate = dr,
  age = rep(ordered(rownames(VADeaths)), length.out = n),
  gender = gl(2, 5, n, labels = c("M", "F")),
  site = gl(2, 10, labels = c("rural", "urban")))
coplot(Drate ~ as.numeric(age) | gender * site, data = d.VAD,
  panel = panel.smooth, xlab = "VADeaths data - Given: gender")
summary(aov.VAD <- aov(Drate ~ .^2, data = d.VAD))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0))
plot(aov.VAD)
par(opar)
```

volcano

Topographic Information on Auckland's Maunga Whau Volcano

Description

Maunga Whau (Mt Eden) is one of about 50 volcanos in the Auckland volcanic field. This data set gives topographic information for Maunga Whau on a 10m by 10m grid.

Usage

```
volcano
```

Format

A matrix with 87 rows and 61 columns, rows corresponding to grid lines running east to west and columns to grid lines running south to north.

Source

Digitized from a topographic map by Ross Ihaka. These data should not be regarded as accurate.

See Also

[filled.contour](#) for a nice plot.

Examples

```
require(grDevices); require(graphics)
filled.contour(volcano, color.palette = terrain.colors, asp = 1)
title(main = "volcano data: filled contour map")
```

warpbreaks	<i>The Number of Breaks in Yarn during Weaving</i>
------------	--

Description

This data set gives the number of warp breaks per loom, where a loom corresponds to a fixed length of yarn.

Usage

```
warpbreaks
```

Format

A data frame with 54 observations on 3 variables.

[,1]	breaks	numeric	The number of breaks
[,2]	wool	factor	The type of wool (A or B)
[,3]	tension	factor	The level of tension (L, M, H)

There are measurements on 9 looms for each of the six types of warp (AL, AM, AH, BL, BM, BH).

anova(fm1)
```

women

Average Heights and Weights for American Women

Description

This data set gives the average heights and weights for American women aged 30–39.

Usage

```
women
```

Format

A data frame with 15 observations on 2 variables.

[, 1]	height	numeric	Height (in)
[, 2]	weight	numeric	Weight (lbs)

Details

The data set appears to have been taken from the American Society of Actuaries *Build and Blood Pressure Study* for some (unknown to us) earlier year.

The World Almanac notes: “The figures represent weights in ordinary indoor clothing and shoes, and heights with shoes”.

Source

The World Almanac and Book of Facts, 1975.

References

McNeil D (1977). *Interactive Data Analysis: A Practical Primer*. John Wiley & Sons. ISBN 978-0471026310.

Examples

```
require(graphics)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)",
     main = "women data: American women aged 30-39")
```

WorldPhones

The World's Telephones

Description

The number of telephones in various regions of the world (in thousands).

Usage

WorldPhones

Format

A matrix with 7 rows and 8 columns. The columns of the matrix give the figures for a given region, and the rows the figures for a year.

The regions are: North America, Europe, Asia, South America, Oceania, Africa, Central America.

The years are: 1951, 1956, 1957, 1958, 1959, 1960, 1961.

Source

McNeil D (1977). *Interactive Data Analysis: A Practical Primer*. John Wiley & Sons. ISBN 978-0471026310.

Examples

```
require(graphics)
matplot(rownames(WorldPhones), WorldPhones, type = "b", log = "y",
        xlab = "Year", ylab = "Number of telephones (1000's)")
legend(1951.5, 80000, colnames(WorldPhones), col = 1:6, lty = 1:5,
       pch = rep(21, 7))
title(main = "World phones data: log scale for response")
```

WWWusage

Internet Usage per Minute

Description

A time series of the numbers of users connected to the Internet through a server every minute.

Usage

WWWusage

Format

A time series of length 100.

Source

Chapter 4

The grDevices package

grDevices-package *The R Graphics Devices and Support for Colours and Fonts*

Description

Graphics devices and support for base and grid graphics

Details

This package contains functions which support both [base](#) and [grid](#) graphics.

For a complete list of functions, use `library(help = "grDevices")`.

Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

adjustcolor *Adjust Colors in One or More Directions Conveniently*

Description

Adjust or modify a vector of colors by “turning knobs” on one or more coordinates in (r, g, b, α) space, typically by up or down scaling them.

Usage

```
adjustcolor(col, alpha.f = 1, red.f = 1, green.f = 1, blue.f = 1,
            offset = c(0, 0, 0, 0),
            transform = diag(c(red.f, green.f, blue.f, alpha.f)))
```

Arguments

<code>col</code>	vector of colors, in any format that <code>col2rgb()</code> accepts
<code>alpha.f</code>	factor modifying the opacity alpha; typically in [0,1]
<code>red.f, green.f, blue.f</code>	factors modifying the “red-”, “green-” or “blue-”ness of the colors, respectively.
<code>offset</code>	numeric vector of length 4 to offset $x := c(r, g, b, \alpha)$, where x is the [0, 1]-scaled result of <code>col2rgb(col, alpha=TRUE)</code> .
<code>transform</code>	a 4x4 numeric matrix applied to $x + \text{offset}$.

Value

a color vector of the same length as `col`, effectively the result of `rgb()`.

See Also

`rgb`, `col2rgb`. For more sophisticated color constructions: `convertColor`

Examples

```
## Illustrative examples :
opal <- palette("default")
stopifnot(identical(adjustcolor(1:8, 0.75),
                        adjustcolor(palette(), 0.75)))
cbind(palette(), adjustcolor(1:8, 0.75))

## alpha = 1/2 * previous alpha --> opaque colors
x <- palette(adjustcolor(palette(), 0.5))

sines <- outer(1:20, 1:4, function(x, y) sin(x / 20 * pi * y))
matplot(sines, type = "b", pch = 21:23, col = 2:5, bg = 2:5,
        main = "Using an 'opaque ('translucent') color palette")

x. <- adjustcolor(x, offset = c(0.5, 0.5, 0.5, 0), # <- "more white"
                 transform = diag(c(.7, .7, .7, 0.6)))
cbind(x, x.)
op <- par(bg = adjustcolor("goldenrod", offset = -rep(.4, 4)), xpd = NA)
plot(0:9, 0:9, type = "n", axes = FALSE, xlab = "", ylab = "",
     main = "adjustcolor() -> translucent")
text(1:8, labels = paste0(x, "++"), col = x., cex = 8)
par(op)

## and

(M <- cbind( rbind( matrix(1/3, 3, 3), 0), c(0, 0, 0, 1)))
adjustcolor(x, transform = M)

## revert to previous palette: active
palette(opal)
```

as.graphicsAnnot *Coerce an Object for Graphics Annotation*

Description

Coerce an R object into a form suitable for graphics annotation.

Usage

```
as.graphicsAnnot(x)
```

Arguments

x an R object

Details

Expressions, calls and names (as used by [plotmath](#)) are passed through unchanged. All other objects with an explicit class (as determined by [is.object](#)) are coerced by [as.character](#) to character vectors.

All the **graphics** and **grid** functions which use this coerce calls and names to expressions internally.

Value

A language object or a character vector.

as.raster *Create a Raster Object*

Description

Functions to create a raster object (representing a bitmap image) and coerce other objects to a raster object.

Usage

```
is.raster(x)
as.raster(x, ...)

## S3 method for class 'matrix'
as.raster(x, max = 1, ...)
## S3 method for class 'array'
as.raster(x, max = 1, ...)

## S3 method for class 'logical'
as.raster(x, max = 1, ...)
## S3 method for class 'numeric'
as.raster(x, max = 1, ...)
## S3 method for class 'character'
as.raster(x, max = 1, ...)
## S3 method for class 'raw'
as.raster(x, max = 255L, ...)
```

Arguments

<code>x</code>	any R object.
<code>max</code>	number giving the maximum of the color values range.
<code>...</code>	further arguments passed to or from other methods.

Details

An object of class "raster" is a matrix of colour values as given by `rgb` representing a bitmap image.

It is not expected that the user will need to call these functions directly; functions to render bitmap images in graphics packages will make use of the `as.raster()` function to generate a raster object from their input.

The `as.raster()` function is (S3) generic so methods can be written to convert other R objects to a raster object.

The default implementation for numeric matrices interprets scalar values on black-to-white scale.

Raster objects can be subsetting like a matrix and it is possible to assign to a subset of a raster object.

There is a method for converting a raster object to a `matrix` (of colour strings).

Raster objects can be compared for equality or inequality (with each other or with a colour string).

There is a `is.na` method which returns a logical matrix of the same dimensions as the raster object. Note that NA values are interpreted as the fully transparent colour by some (but not all) graphics devices.

Value

For `as.raster()`, a raster object.

For `is.raster()`, a logical indicating whether `x` is a raster object.

Note

Raster images are internally represented row-first, which can cause confusion when trying to manipulate a raster object. The recommended approach is to coerce a raster to a matrix, perform the manipulation, then convert back to a raster.

Examples

```
# A red gradient
as.raster(matrix(hcl(0, 80, seq(50, 80, 10)),
                 nrow = 4, ncol = 5))

# Vectors are 1-column matrices ...
#   character vectors are color names ...
as.raster(hcl(0, 80, seq(50, 80, 10)))
#   numeric vectors are greyscale ...
as.raster(1:5, max = 5)
#   logical vectors are black and white ...
as.raster(1:10 %% 2 == 0)

# ... unless nrow/ncol are supplied ...
as.raster(1:10 %% 2 == 0, nrow = 1)

# Matrix can also be logical or numeric (or raw) ...
```

```

as.raster(matrix(c(TRUE, FALSE), nrow = 3, ncol = 2))
as.raster(matrix(1:3/4, nrow = 3, ncol = 4))

# An array can be 3-plane numeric (R, G, B planes) ...
as.raster(array(c(0:1, rep(0.5, 4)), c(2, 1, 3)))

# ... or 4-plane numeric (R, G, B, A planes)
as.raster(array(c(0:1, rep(0.5, 6)), c(2, 1, 4)))

# subsetting
r <- as.raster(matrix(colors()[1:100], ncol = 10))
r[, 2]
r[2:4, 2:5]

# assigning to subset
r[2:4, 2:5] <- "white"

# comparison
r == "white"

```

axisTicks

*Compute Pretty Axis Tick Scales***Description**

Compute pretty axis scales and tick mark locations, the same way as traditional R graphics do it. This is interesting particularly for log scale axes.

Usage

```

axisTicks(usr, log, axp = NULL, nint = 5)
.axisPars(usr, log = FALSE, nintLog = 5)

```

Arguments

usr	numeric vector of length 2, with <code>c(min, max)</code> axis extents. Corresponds to traditional graphics ' <code>par("usr")</code> , and hence for <code>log = TRUE</code> needs to use <code>log10()</code> transformed coordinates.
log	logical indicating if a log scale is (thought to be) in use.
axp	numeric vector of length 3, <code>c(mi, ma, n.)</code> , with identical meaning to <code>par("?axp")</code> (where ? is x or y), namely “pretty” axis extents, and an integer <i>code n.</i>
nint, nintLog	positive integer value indicating (<i>approximately</i>) the desired number of intervals. <code>nintLog</code> is used only for the case <code>log = TRUE</code> .

Details

`axisTicks(usr, *)` calls `.axisPars(usr, ..)` to set `axp` when that is missing or `NULL`.

Apart from that, `axisTicks()` just calls the C function `CreateAtVector()` in 'R/src/main/plot.c' which is also called by the base **graphics** package function `axis(side, *)` when its argument `at` is not specified.

Since R 4.1.0, the underlying C `CreateAtVector()` has been tuned to provide a considerably more balanced (symmetric) set of tick locations.

Value

`axisTicks()` returns a numeric vector of potential axis tick locations in case of `log=TRUE` in the original scale, of length approximately `nint+1`.

`.axisPars()` returns a **list** with components

`axp` numeric vector of length 2, `c(min., max.)`, of pretty axis extents.

`n` integer (code), with the same meaning as `par("?axp")[3]`.

See Also

`axTicks`, `axis`, and `par` all from the **graphics** package.

Examples

```
##--- Demonstrating correspondence between graphics'
##--- axis() and the graphics-engine agnostic axisTicks() :

require("graphics")
plot(10*(0:10)); (pu <- par("usr"))
aX <- function(side, at = at, labels = FALSE, lwd.ticks = 2, col.ticks = 2,
               tck = 0.05, ...)
  axis(side, at = at, labels = FALSE, lwd.ticks = 2, col.ticks = 2,
        tck = 0.05, ...)
aX(1, print(xa <- axisTicks(pu[1:2], log = FALSE))) # x axis
aX(2, print(ya <- axisTicks(pu[3:4], log = FALSE))) # y axis

axisTicks(pu[3:4], log = FALSE, nint = 10)

## ----- Log Scale -----
x <- c(10, 1000)
#
axisTicks(log10(x), log = TRUE) # 10 20 50 .... 1000

plot(10*(0:10), log = "y"); (pu <- par("usr")) # ... ... 0.96 2.04
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # 10 20 50 100 (y axis)

plot(2^(0:9), log = "y"); (pu <- par("usr"))
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # y axis
## 'usr' corresponds to log10(<range>) :
stopifnot(ya == axisTicks(log10(c(1, 512)), log=TRUE))
```

boxplot.stats	Box Plot Statistics
---------------	---------------------

Description

This function is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

Usage

```
boxplot.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE)
```

Arguments

<code>x</code>	a numeric vector for which the boxplot will be constructed (NAs and NaNs are allowed and omitted).
<code>coef</code>	this determines how far the plot ‘whiskers’ extend out from the box. If <code>coef</code> is positive, the whiskers extend to the most extreme data point which is no more than <code>coef</code> times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).
<code>do.conf, do.out</code>	logicals; if FALSE, the <code>conf</code> or <code>out</code> component respectively will be empty in the result.

Details

The two ‘hinges’ are versions of the first and third quartile, i.e., close to `quantile(x, c(1, 3)/4)`. The hinges equal the quartiles for odd n (where $n <- \text{length}(x)$) and differ for even n . Whereas the quartiles only equal observations for $n \% 4 == 1$ ($n \equiv 1 \pmod{4}$), the hinges do so *additionally* for $n \% 4 == 2$ ($n \equiv 2 \pmod{4}$), and are in the middle of two observations otherwise.

The notches (if requested) extend to $\pm 1.58 \text{ IQR} / \sqrt{n}$. This seems to be based on the same calculations as the formula with 1.57 in Chambers, Cleveland, Kleiner, and Tukey (1983, p. 62)), given in McGill, Tukey, and Larsen (1978, p. 16)). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.

Value

A list with named components as follows:

<code>stats</code>	a vector of length 5, containing the extreme of the lower whisker, the lower ‘hinge’, the median, the upper ‘hinge’ and the extreme of the upper whisker. For <code>coef = 0</code> , this vector is identical to <code>fivenum(x, na.rm = TRUE)</code> .
<code>n</code>	the number of non-NA observations in the sample.
<code>conf</code>	the lower and upper extremes of the ‘notch’ (if <code>do.conf</code>). See the details.
<code>out</code>	the values of any data points which lie beyond the extremes of the whiskers (if <code>do.out</code>).

Note that `stats` and `conf` are sorted in *increasing* order, unlike S, and that `n` and `out` include any $\pm \text{Inf}$ values.

Examples

```
require(stats)
x <- c(1:100, 1000)
(b1 <- boxplot.stats(x))
(b2 <- boxplot.stats(x, do.conf = FALSE, do.out = FALSE))
stopifnot(b1 $ stats == b2 $ stats) # do.out = FALSE is still robust
boxplot.stats(x, coef = 3, do.conf = FALSE)

## no outlier treatment:
(b3 <- boxplot.stats(x, coef = 0))
stopifnot(b3$stats == fivenum(x))

## missing values are ignored
stopifnot(identical(boxplot.stats(c(x, NA)), b1))
## ... infinite values are not:
(r <- boxplot.stats(c(x, -1:1/0)))
stopifnot(r$out == c(1000, -Inf, Inf))
```

bringToTop

Assign Focus to a Window

Description

Available only on Windows.

`bringToTop` brings the specified screen device’s window to the front of the window stack (and gives it focus). With first argument `-1` it brings the console to the top.

If `stay = TRUE`, the window is designated as a topmost window, i.e. it will stay on top of any regular window. `stay` may only be used when RGui is run in SDI mode. This corresponds to the “Stay on top” popup menu item in RGui.

Usage

```
bringToTop(which = dev.cur(), stay = FALSE)
```

Arguments

<code>which</code>	a device number, or <code>-1</code> .
<code>stay</code>	whether to make the window stay on top.

cairo

Cairographics-based SVG, PDF and PostScript Graphics Devices

Description

Graphics devices for SVG, PDF and PostScript graphics files using the cairo graphics API.

Usage

```
svg(filename = if(onefile) "Rplots.svg" else "Rplot%03d.svg",
     width = 7, height = 7, pointsize = 12,
     onefile = FALSE, family = "sans", bg = "white",
     antialias = c("default", "none", "gray", "subpixel"),
     symbolfamily)

cairo_pdf(filename = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
          width = 7, height = 7, pointsize = 12,
          onefile = TRUE, family = "sans", bg = "white",
          antialias = c("default", "none", "gray", "subpixel"),
          fallback_resolution = 300, symbolfamily)

cairo_ps(filename = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
         width = 7, height = 7, pointsize = 12,
         onefile = TRUE, family = "sans", bg = "white",
         antialias = c("default", "none", "gray", "subpixel"),
         fallback_resolution = 300, symbolfamily)
```

Arguments

<code>filename</code>	the file path of the output file(s). The page number is substituted if a C integer format is included in the character string, as in the default. (Depending on the platform, the result must be less than <code>PATH_MAX</code> characters long, and may be truncated if not. See pdf for further details.) Tilde expansion is performed where supported by the platform.
<code>width</code>	the width of the device in inches.
<code>height</code>	the height of the device in inches.
<code>pointsize</code>	the default pointsize of plotted text (in big points).

<code>onefile</code>	should all plots appear in one file or in separate files?
<code>family</code>	one of the device-independent font families, "sans", "serif" and "mono", or a character string specify a font family to be searched for in a system-dependent way. On unix-alikes (incl. macOS), see the 'Cairo fonts' section in the help for X11 .
<code>bg</code>	the initial background colour: can be overridden by setting <code>par("bg")</code> .
<code>antialias</code>	string, the type of anti-aliasing (if any) to be used; defaults to "default".
<code>fallback_resolution</code>	numeric: the resolution in dpi used when falling back to bitmap output.
<code>symbolfamily</code>	a length-one character string that specifies the font family to be used as the "symbol" font (e.g., for plotmath output).

Details

SVG (Scalar Vector Graphics) is a W3C standard for vector graphics. See <https://www.w3.org/groups/wg/svg/>. The output from `svg` is SVG version 1.1 for `onefile = FALSE` (the default), otherwise SVG 1.2. (SVG 1.2 never passed the draft stage. Few SVG viewers are capable of displaying multi-page SVG files, and they have been dropped from SVG 2.0 (still in draft).)

Note that unlike `pdf` and `postscript`, `cairo_pdf` and `cairo_ps` sometimes record *bitmaps* and not vector graphics. On the other hand, they can (on suitable platforms) include a much wider range of UTF-8 glyphs, and embed the fonts used.

The output produced by `cairo_ps(onefile = FALSE)` will be encapsulated postscript on a platform with `cairo >= 1.6`.

R can be compiled without support for any of these devices: this will be reported if you attempt to use them on a system where they are not supported.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in `filename` (or set `onefile = TRUE`) the file will contain the last page plotted.

There is full support of semi-transparency, but using this is one of the things liable to trigger bitmap output (and will always do so for `cairo_ps`).

Value

A plot device is opened: nothing is returned to the R interpreter.

Anti-aliasing

Anti-aliasing is applied to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for `image` plots, and so is never used for fills.

`antialias = "default"` is in principle platform-dependent, but seems most often equivalent to `antialias = "gray"`.

Conventions

This section describes the implementation of the conventions for graphics devices set out in [R Internals](#).

- The default device size is in pixels (`svg`) or inches.
- Font sizes are in big points.

- The default font family is Helvetica.
- Line widths are multiples of 1/96 inch.
- Circle radii have a minimum of 1/72 inch.
- Colours are interpreted by the viewing application.

Warning

Support for all these devices are optional, so in packages they should be used conditionally after checking `capabilities("cairo")`.

Note

In principle these devices are independent of X11 (as is seen by their presence on Windows). But on a Unix-alike the cairo libraries may be distributed as part of the X11 system and hence that (for example, on macOS, XQuartz) may need to be installed.

See Also

`Devices`, `dev.print`, `pdf`, `postscript`
`capabilities` to see if cairo is supported.

cairoSymbolFont	<i>Specify a Symbol Font</i>
-----------------	------------------------------

Description

Specify a symbol font for a Cairo-based graphics device. This function provides the opportunity to specify whether the font supports Private Use Area code points.

Usage

```
cairoSymbolFont(family, usePUA = TRUE)
```

Arguments

family	A character vector giving the symbol font family name.
usePUA	Does the font support Private Use Area code points?

Details

On Cairo-based graphics devices, when drawing with a symbol font (e.g., `plotmath`), Adobe Symbol Encoding characters are converted to UTF-8 code points. This conversion can use Private Use Area code points or not. It is useful to be able to specify this option because some fonts (e.g., the OpenSymbol font that is included in LibreOffice) have glyphs mapped to the Private Use Area and some fonts (e.g., Nimbus Sans L, the URW Fonts equivalent of Helvetica) do not.

Value

An object of class "CairoSymbolFont".

See Also

[cairo_pdf.](#)

Examples

```
## Not run:
## If a font uses PUA, we can just specify the font name ...
cairo_pdf(symbolfamily="OpenSymbol")
dev.off()
## ... or equivalently ...
cairo_pdf(symbolfamily=cairoSymbolFont("OpenSymbol"))
dev.off()

## If a font does not use PUA, we must indicate that ...
cairo_pdf(symbolfamily=cairoSymbolFont("Nimbus Sans", usePUA=FALSE))
dev.off()

## End(Not run)
```

check.options

Set Options with Consistency Checks

Description

Utility function for setting options with some consistency checks. The [attributes](#) of the new settings in `new` are checked for consistency with the *model* (often default) list in `name.opt`.

Usage

```
check.options(new, name.opt, reset = FALSE, assign.opt = FALSE,
              envir = .GlobalEnv,
              check.attributes = c("mode", "length"),
              override.check = FALSE)
```

Arguments

<code>new</code>	a <i>named</i> list
<code>name.opt</code>	character with the name of R object containing the default list.
<code>reset</code>	logical; if TRUE, reset the options from <code>name.opt</code> . If there is more than one R object with name <code>name.opt</code> , remove the first one in the search() path.
<code>assign.opt</code>	logical; if TRUE, assign the ...
<code>envir</code>	the environment used for get and assign .
<code>check.attributes</code>	character containing the attributes which <code>check.options</code> should check.
<code>override.check</code>	logical vector of length <code>length(new)</code> (or 1 which entails recycling). For those <code>new[i]</code> where <code>override.check[i] == TRUE</code> , the checks are overridden and the changes made anyway.

Value

A list of components with the same names as the one called `name.opt`. The values of the components are changed from the `new` list, as long as these pass the checks (when these are not overridden according to `override.check`).

Note

Option "names" is exempt from all the checks or warnings, as in the application it can be `NULL` or a variable-length character vector.

Author(s)

Martin Maechler

See Also

[ps.options](#) and [pdf.options](#), which use `check.options`.

Examples

```
(L1 <- list(a = 1:3, b = pi, ch = "CH"))
check.options(list(a = 0:2), name.opt = "L1")
check.options(NULL, reset = TRUE, name.opt = "L1")
```

`chull`*Compute Convex Hull of a Set of Points*

Description

Computes the subset of points which lie on the convex hull of the set of points specified.

Usage

```
chull(x, y = NULL)
```

Arguments

`x, y` coordinate vectors of points. This can be specified as two vectors `x` and `y`, a 2-column matrix `x`, a list `x` with two components, etc, see [xy.coords](#).

Details

[xy.coords](#) is used to interpret the specification of the points. Infinite, missing and `NaN` values are not allowed.

The algorithm is that given by Eddy (1977a); Eddy (1977b).

Value

An integer vector giving the indices of the unique points lying on the convex hull, in clockwise order. (The first will be returned for duplicate points.)

See Also

`xy.coords`, `polygon`

Examples

```
X <- matrix(stats::rnorm(2000), ncol = 2)
chull(X)

plot(X, cex = 0.5)
polygon(X[chull(X), ], )
```

cm

Unit Transformation

Description

Translates from inches to cm (centimeters).

Usage

```
cm(x)
```

Arguments

`x` numeric vector (in inches)

Value

$2.54 * x$, in centimeters.

Examples

```
cm(1) # = 2.54

## Translate *from* cm *to* inches:

10 / cm(1) # -> 10cm are 3.937 inches
```

col2rgb*Color to RGB Conversion*

Description

R color to RGB (red/green/blue) conversion.

Usage

```
col2rgb(col, alpha = FALSE)
```

Arguments

col	vector of any of the three kinds of R color specifications, i.e., either a color name (as listed by <code>colors()</code>), a hexadecimal string (see Details), or a positive integer <code>i</code> meaning <code>palette()[i]</code> .
alpha	logical value indicating whether the alpha channel (opacity) values should be returned.

Details

`NA` (as integer or character) and `"NA"` mean transparent, which can also be specified as `"transparent"`.

Values of `col` not of one of these types are coerced: real vectors are coerced to integer and other types to character. (factors are coerced to character: in all other cases the class is ignored when doing the coercion.)

Hexadecimal string colors can be in the long hexadecimal form (e.g., `"#rrggbb"` or `"#rrggbbbaa"`) or the short form (e.g., `"#rgb"` or `"#rgba"`). The short form is expanded to the long form by replicating digits (not by adding zeroes), e.g., `"#rgb"` becomes `"#rrggbb"`.

Zero and negative values of `col` are an error.

Value

An integer matrix with three or four (for `alpha = TRUE`) rows and number of columns the length of `col`. If `col` has names these are used as the column names of the return value.

Author(s)

Martin Maechler and the R core team.

See Also

`rgb`, `colors`, `palette`, etc.

The newer, more flexible interface, `convertColor()`.

Examples

```

col2rgb("peachpuff")
col2rgb(c(blu = "royalblue", reddish = "tomato")) # note: colnames

col2rgb(1:8) # the ones from the palette() (if the default)

col2rgb(paste0("gold", 1:4))

col2rgb("#08a0ff")
## all three kinds of color specifications:
col2rgb(c(red = "red", hex = "#abcdef"))
col2rgb(c(palette = 1:3))

# long and short form of hexadecimal notation
col2rgb(c(long = "#559955", short = "#595"))
# with alpha
col2rgb(c(long = "#559955BB", short = "#595B"), alpha = TRUE)

##-- NON-INTRODUCTORY examples --

grC <- col2rgb(paste0("gray", 0:100))
table(print(diff(grC["red",]))) # '2' or '3': almost equidistant
## The 'named' grays are in between {"slate gray" is not gray, strictly}
col2rgb(c(g66 = "gray66", darkg = "dark gray", g67 = "gray67",
          g74 = "gray74", gray = "gray", g75 = "gray75",
          g82 = "gray82", light = "light gray", g83 = "gray83"))

crgb <- col2rgb(cc <- colors())
colnames(crgb) <- cc
t(crgb) # The whole table

## How many names are 'aliases' of each other?
ccodes <- c(256^(2:0) %**% crgb)
cl <- split(cc, ccodes)
length(cl) # 502 distinct colors
table(tcc <- lengths(cl))
## All the multiply named colors:
clmult <- cl[tcc >= 2]
names(clmult) <- sapply(clmult, function(x) paste(crgb[,x[1]], collapse = ","))
utils::str(clmult)

## Look at the color cube:
tc <- t(crgb[, !duplicated(ccodes)])
cNms <- rownames(tc)
if(requireNamespace("lattice", quietly = TRUE))
  lattice::cloud(blue ~ red + green, data = as.data.frame(tc), col = cNms)
## The 8 corners of the color cube:
isC <- rowSums(tc == 0 | tc == 255) == 3
cNms[isC] # "white" "black" "blue" "cyan" "green" "magenta" "red" "yellow"

table(is.gray <- tc[,1] == tc[,2] & tc[,2] == tc[,3]) # (397, 105)

## Not run: ## Look at the color cube dynamically:
if(require("rgl")) {
  open3d(windowRect = c(50,50, 950, 950)) # large, so we see details
  plot3d(tc, col = cNms, size = 11) # --> rotate w/ mouse; enlarged corners:

```

```

points3d(tc[isC,], col = cNms[isC], size=22)
bg3d("darkgray") # (to "see more"); rotate around gray-axis:
play3d(spin3d(axis = c(1, 1, 1), rpm = 2), duration = 30)
if(FALSE) # add all names {zoom in with 2nd mouse button!}
  text3d(tc[!is.gray,], texts = cNms[!is.gray],
         col = cNms[!is.gray], adj=-1/4, cex = 1/2)
if(FALSE) { ## next version of {rgl}
  hover3d(tc, labels = cNms)
  message("Move mouse over plot to identify points.")
} else { ## click on blob to see colors() ' name:
  identify3d(tc, labels=cNms)
}
}

## End(Not run)

```

colorRamp

Color interpolation

Description

These functions return functions that interpolate a set of given colors to create new color palettes (like [topo.colors](#)) and color ramps, functions that map the interval [0, 1] to colors (like [grey](#)).

Usage

```

colorRamp(colors, bias = 1, space = c("rgb", "Lab"),
          interpolate = c("linear", "spline"), alpha = FALSE)
colorRampPalette(colors, ...)

```

Arguments

colors	colors to interpolate; must be a valid argument to col2rgb() .
bias	a positive number. Higher values give more widely spaced colors at the high end.
space	a character string; interpolation in RGB or CIE Lab color spaces.
interpolate	use spline or linear interpolation.
alpha	logical: should alpha channel (opacity) values be returned? It is an error to give a true value if <code>space</code> is specified.
...	arguments to pass to colorRamp .

Details

The CIE Lab color space is approximately perceptually uniform, and so gives smoother and more uniform color ramps. On the other hand, palettes that vary from one hue to another via white may have a more symmetrical appearance in RGB space.

The conversion formulas in this function do not appear to be completely accurate and the color ramp may not reach the extreme values in Lab space. Future changes in the R color model may change the colors produced with `space = "Lab"`.

Value

colorRamp returns a [function](#) with argument a vector of values between 0 and 1 that are mapped to a numeric matrix of RGB color values with one row per color and 3 or 4 columns.

colorRampPalette returns a function that takes an integer argument (the required number of colors) and returns a character vector of colors (see [rgb](#)) interpolating the given sequence (similar to [heat.colors](#) or [terrain.colors](#)).

See Also

Good starting points for interpolation are the “sequential” and “diverging” ColorBrewer palettes in the [RColorBrewer](#) package.

[splinefun](#) or [approxfun](#) are used for interpolation.

Examples

```
## Both return a *function* :
colorRamp(c("red", "green"))( (0:4)/4 ) ## (x) , x in [0,1]
colorRampPalette(c("blue", "red"))( 4 ) ## (n)
## a ramp in opacity of blue values
colorRampPalette(c(rgb(0,0,1,1), rgb(0,0,1,0)), alpha = TRUE)(8)

require(graphics)

## Here space="rgb" gives palettes that vary only in saturation,
## as intended.
## With space="Lab" the steps are more uniform, but the hues
## are slightly purple.
filled.contour(volcano,
               color.palette =
                 colorRampPalette(c("red", "white", "blue")),
               asp = 1)
filled.contour(volcano,
               color.palette =
                 colorRampPalette(c("red", "white", "blue"),
                                   space = "Lab"),
               asp = 1)

## Interpolating a 'sequential' ColorBrewer palette
YlOrBr <- c("#FFFFD4", "#FED98E", "#FE9929", "#D95F0E", "#993404")
filled.contour(volcano,
               color.palette = colorRampPalette(YlOrBr, space = "Lab"),
               asp = 1)
filled.contour(volcano,
               color.palette = colorRampPalette(YlOrBr, space = "Lab",
                                                 bias = 0.5),
               asp = 1)

## 'jet.colors' is "as in Matlab"
## (and hurting the eyes by over-saturation)
jet.colors <-
  colorRampPalette(c("#00007F", "blue", "#007FFF", "cyan",
                      "#7FFF7F", "yellow", "#FF7F00", "red", "#7F0000"))
filled.contour(volcano, color.palette = jet.colors, asp = 1)

## space="Lab" helps when colors don't form a natural sequence
```

```

m <- outer(1:20,1:20,function(x,y) sin(sqrt(x*y)/3))
rgb.palette <- colorRampPalette(c("red", "orange", "blue"),
                               space = "rgb")
Lab.palette <- colorRampPalette(c("red", "orange", "blue"),
                               space = "Lab")
filled.contour(m, col = rgb.palette(20))
filled.contour(m, col = Lab.palette(20))

```

colors

Color Names

Description

Returns the built-in color names which R knows about.

Usage

```

colors (distinct = FALSE)
colours(distinct = FALSE)

```

Arguments

`distinct` logical indicating if the colors returned should all be distinct; e.g., "snow" and "snow1" are effectively the same point in the $(0 : 255)^3$ RGB space.

Details

These color names can be used with a `col=` specification in graphics functions.

An even wider variety of colors can be created with primitives `rgb`, `hsv` and `hcl`, or the derived `rainbow`, `heat.colors`, etc.

"transparent" is not a color and so not listed, but it is accepted as a color specification.

Value

A character vector containing all the built-in color names.

See Also

[palette](#) for setting the 'palette' of colors for `col=index` specifications.

[rgb](#), [hsv](#), [hcl](#), [gray](#); [rainbow](#) for a nice example; and [heat.colors](#), [topo.colors](#) for images.

[col2rgb](#) for translating to RGB numbers and extended examples.

Examples

```

cl <- colors()
length(cl); cl[1:20]

length(cl. <- colors(TRUE))
## only 502 of the 657 named ones

## ----- Show all named colors and more:
demo("colors")
## -----

```

contourLines

Calculate Contour Lines

Description

Calculate contour lines for a given set of data.

Usage

```
contourLines(x = seq(0, 1, length.out = nrow(z)),
             y = seq(0, 1, length.out = ncol(z)),
             z, nlevels = 10,
             levels = pretty(range(z, na.rm = TRUE), nlevels))
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a <code>list</code> , its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively. If the list has component <code>z</code> this is used for <code>z</code> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>nlevels</code>	number of contour levels desired iff <code>levels</code> is not supplied.
<code>levels</code>	numeric vector of levels at which to draw contour lines.

Details

`contourLines` draws nothing, but returns a set of contour lines.

There is currently no documentation about the algorithm. The source code is in [‘R_HOME/src/main/plot3d.c’](#).

Value

A `list` of contours, each itself a `list` with elements:

<code>level</code>	The contour level.
<code>x</code>	The x-coordinates of the contour.
<code>y</code>	The y-coordinates of the contour.

See Also

`options("max.contour.segments")` for the maximal complexity of a single contour line.
[contour](#): Its ‘Examples’ demonstrate how `contourLines()` can be drawn and are the same (as those from `contour()`).

Examples

```
x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
cl <- contourLines(x, y, volcano)
## summarize the sizes of each the contour lines :
cbind(lev = vapply(cl, `[`, .5, "level"),
      n = vapply(cl, function(l) length(l$x), 1))

z <- outer(-9:25, -9:25)
pretty(range(z), 10) # -300 -200 ... 600 700
utils::str(c2 <- contourLines(z))
# no segments for {-300, 700};
# 2 segments for {-200, -100, 0}
# 1 segment for 100:600
```

 convertColor

Convert between Colour Spaces

Description

Convert colours between their representations in standard colour spaces.

Usage

```
convertColor(color, from, to, from.ref.white, to.ref.white,
             scale.in = 1, scale.out = 1, clip = TRUE)
```

Arguments

color	A matrix whose rows specify colors. The function will also accept a data frame, but will silently convert to a matrix internally.
from,to	Input and output color spaces. See ‘Details’ below.
from.ref.white,to.ref.white	Reference whites or NULL if these are built in to the definition, as for RGB spaces. D65 is the default, see ‘Details’ for others.
scale.in,scale.out	Input is divided by scale.in, output is multiplied by scale.out. Use NULL to suppress scaling when input or output is not numeric.
clip	If TRUE, truncate RGB output to [0,1], FALSE return out-of-range RGB, NA set out of range colors to NaN.

Details

Color spaces are specified by objects of class `colorConverter`, created by `colorConverter` or `make.rgb`. Built-in color spaces may be referenced by strings: "XYZ", "sRGB", "Apple RGB", "CIE RGB", "Lab", "Luv". The converters for these colour spaces are in the object `colorspaces`.

The "sRGB" color space is that used by standard PC monitors. "Apple RGB" is used by Apple monitors. "Lab" and "Luv" are approximately perceptually uniform spaces standardized by the Commission Internationale d'Eclairage. XYZ is a 1931 CIE standard capable of representing all visible colors (and then some), but not in a perceptually uniform way.

The Lab and Luv spaces describe colors of objects, and so require the specification of a reference 'white light' color. Illuminant D65 is a standard indirect daylight, Illuminant D50 is close to direct sunlight, and Illuminant A is the light from a standard incandescent bulb. Other standard CIE illuminants supported are B, C, E and D55. RGB colour spaces are defined relative to a particular reference white, and can be only approximately translated to other reference whites. The von Kries chromatic adaptation algorithm is used for this. Prior to R 3.6, color conversions involving color spaces created with `make.rgb` were carried out assuming a D65 illuminant, irrespective of the actual illuminant used in the creation of the color space. This affected the built-in "CIE RGB" color space.

The RGB color spaces are specific to a particular class of display. An RGB space cannot represent all colors, and the `clip` option controls what is done to out-of-range colors.

For the named color spaces `color` must be a matrix of values in the `from` color space: in particular opaque colors.

Value

A 3-column matrix whose rows specify the colors.

srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=60")

Lab <- cbind(L = 80, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
clipped <- attr(na.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), ncol = 26), col = cols,
      xlab = "a", ylab = "b", main = "Lab: L=80")

cols <- t(col2rgb(palette())); rownames(cols) <- palette(); cols
zapsmall(lab <- convertColor(cols, from = "sRGB", to = "Lab", scale.in = 255))
stopifnot(all.equal(cols, # converting back.. getting the original:
  round(convertColor(lab, from = "Lab", to = "sRGB", scale.out = 255)),
  check.attributes = FALSE))

```

densCols

Colors for Smooth Density Plots

Description

`densCols` produces a vector containing colors which encode the local densities at each point in a scatterplot.

Usage

```

densCols(x, y = NULL, nbin = 128, bandwidth,
         colramp = colorRampPalette(blues9[-(1:3)]))
blues9

```

Arguments

<code>x, y</code>	the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates of the points. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details. If supplied separately, they must be of the same length.
<code>nbin</code>	numeric vector of length one (for both directions) or two (for <code>x</code> and <code>y</code> separately) specifying the number of equally spaced grid points for the density estimation; directly used as <code>gridsize</code> in bkde2D() .
<code>bandwidth</code>	numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. <code>bandwidth</code> is subsequently passed to function bkde2D .
<code>colramp</code>	function accepting an integer <code>n</code> as an argument and returning <code>n</code> colors.

Details

`densCols` computes and returns the set of colors that will be used in plotting, calling [bkde2D](#) (`*`, `bandwidth`, `gridsize = nbin`, ...) from package **KernSmooth**.

`blues9` is a set of 9 color shades of blue used as the default in plotting.

Value

`densCols` returns a vector of length `nrow(x)` that contains colors to be used in a subsequent scatterplot. Each color represents the local density around the corresponding point.

Author(s)

Florian Hahne at FHCRC, originally

See Also

`bkde2D` from package **KernSmooth**; further, `smoothScatter()` (package **graphics**) which builds on the same computations as `densCols`.

Examples

```
x1 <- matrix(rnorm(1e3), ncol = 2)
x2 <- matrix(rnorm(1e3, mean = 3, sd = 1.5), ncol = 2)
x  <- rbind(x1, x2)

dcols <- densCols(x)
graphics::plot(x, col = dcols, pch = 20, main = "n = 1000")
```

dev

Control Multiple Devices

Description

These functions provide control over multiple graphics devices.

Usage

```
dev.cur()
dev.list()
dev.next(which = dev.cur())
dev.prev(which = dev.cur())
dev.off(which = dev.cur())
dev.set(which = dev.next())
dev.new(..., noRStudioGD = FALSE)
graphics.off()
```

Arguments

<code>which</code>	An integer specifying a device number.
<code>...</code>	arguments to be passed to the device selected.
<code>noRStudioGD</code>	Do not use the RStudio graphics device even if specified as the default device: it does not accept arguments such as <code>width</code> and <code>height</code> .

Details

Only one device is the ‘active’ device: this is the device in which all graphics operations occur. There is a “null device” which is always open but is really a placeholder: any attempt to use it will open a new device specified by `getOption("device")`.

Devices are associated with a name (e.g., “X11” or “postscript”) and a number in the range 1 to 63; the “null device” is always device 1. Once a device has been opened the null device is not considered as a possible active device. There is a list of open devices, and this is considered as a circular list not including the null device. `dev.next` and `dev.prev` select the next open device in the appropriate direction, unless no device is open.

`dev.off` shuts down the specified (by default the current) device. If the current device is shut down and any other devices are open, the next open device is made current. It is an error to attempt to shut down device 1. `graphics.off()` shuts down all open graphics devices. Normal termination of a session runs the internal equivalent of `graphics.off()`.

`dev.set` makes the specified device the active device. If there is no device with that number, it is equivalent to `dev.next`. If `which = 1` it opens a new device and selects that.

`dev.new` opens a new device. Normally R will open a new device automatically when needed, but this enables you to open further devices in a platform-independent way. (For which device is used see `getOption("device")`.) Note that care is needed with file-based devices such as `pdf` and `postscript` and in that case file names such as ‘Rplots.pdf’, ‘Rplots1.pdf’, ..., ‘Rplots999.pdf’ are tried in turn. Only named arguments are passed to the device, and then only if they match the argument list of the device. Even so, care is needed with the interpretation of e.g. `width`, and for the standard bitmap devices `units = "in"`, `res = 72` is forced if neither is supplied but both `width` and `height` are.

Value

`dev.cur` returns a length-one named integer vector giving the number and name of the active device, or 1, the null device, if none is active.

`dev.list` returns the numbers of all open devices, except device 1, the null device. This is a numeric vector with a `names` attribute giving the device names, or `NULL` if there is no open device.

`dev.next` and `dev.prev` return the number and name of the next / previous device in the list of devices. This will be the null device if and only if there are no open devices.

`dev.off` returns the number and name of the new active device (after the specified device has been shut down).

`dev.set` returns the number and name of the new active device.

`dev.new` returns the return value of the device opened, usually invisible `NULL`.

[layout](#) and its links for setting up plotting regions on the current device.

Examples

```
## Not run: ## Unix-specific example
x11()
plot(1:10)
x11()
plot(rnorm(10))
dev.set(dev.prev())
```

```
abline(0, 1) # through the 1:10 points
dev.set(dev.next())
abline(h = 0, col = "gray") # for the residual plot
dev.set(dev.prev())
dev.off(); dev.off() #- close the two X devices

## End(Not run)
```

dev.capabilities *Query Capabilities of the Current Graphics Device*

Description

Query the capabilities of the current graphics device.

Usage

```
dev.capabilities(what = NULL)
```

Arguments

what	a character vector partially matching the names of the components listed in section ‘Value’, or NULL which lists all available capabilities.
------	--

Details

The capabilities have to be specified by the author of the graphics device, unless they can be deduced from missing hooks. Thus they will often be returned as NA, and may reflect the maximal capabilities of the underlying device where several output formats are supported by one device.

Most recent devices support semi-transparent colours provided the graphics format does (which PostScript does not). On the other hand, relatively few graphics formats support (fully or semi-) transparent backgrounds: generally the latter is found only in PDF and PNG plots.

Value

A named list with some or all of the following components, any of which may take value NA:

semiTransparency	logical: Does the device support semi-transparent colours?
transparentBackground	character: Does the device support (semi)-transparent backgrounds? Possible values are "no", "fully" (only full transparency) and "semi" (semi-transparent background colours are supported).
rasterImage	character: To what extent does the device support raster images as used by rasterImage and grid.raster ? Possible values "no", "yes" and "non-missing" (support only for arrays without any missing values).
capture	logical: Does the current device support raster capture as used by grid.cap ?
locator	logical: Does the current device support locator and identify ?
events	character: Which events can be generated on this device? Currently this will be a subset of <code>c("MouseDown", "MouseMove", "MouseUp", "Keybd", "Idle")</code> , but other events may be supported in the future.

patterns	character: Does the device support pattern fills? One or more of <code>c("LinearGradient", "RadialGradient", "TilingPattern")</code> May also be FALSE.
clippingPaths	logical: Does the device support clipping paths?
masks	character: Does the device support masks? One or more of <code>c("alpha", "luminance")</code> May also be FALSE.
compositing	character: Does the device support compositing operators? There are many possible operators and devices may support any subset. For example the pdf device supports a set of “blend modes” whereas Cairo-based devices support Porter-Duff operators as well. May also be FALSE.
transformations	logical: Does the devices support affine transformations ?
paths	logical: Does the device support stroking and filling paths?
glyphs	logical: Does the device support rendering glyphs?

See Also

See [getGraphicsEvent](#) for details on interactive events.

Examples

```
dev.capabilities()
```

dev.capture	<i>Capture device output as a raster image</i>
-------------	--

Description

`dev.capture` captures the current contents of a graphics device as a raster (bitmap) image.

Usage

```
dev.capture(native = FALSE)
```

Arguments

native	Logical. If FALSE the result is a matrix of R color names, if TRUE the output is returned as a <code>nativeRaster</code> object which is more efficient for plotting, but not portable.
--------	---

Details

Not all devices support capture of the output as raster bitmaps. Typically, only image-based devices do and even not all of them.

Value

NULL if the device does not support capture, otherwise a matrix of color names (for `native = FALSE`) or a `nativeRaster` object (for `native = TRUE`).

dev.flush

Hold or Flush Output on an On-Screen Graphics Device

Description

This gives a way to hold/flush output on certain on-screen devices, and is ignored by other devices.

Usage

```
dev.hold(level = 1L)
dev.flush(level = 1L)
```

Arguments

`level` Integer ≥ 0 . The amount by which to change the hold level. Negative values will be silently replaced by zero.

Details

Devices which implement this maintain a stack of hold levels: calling `dev.hold` increases the level and `dev.flush` decreases it. Calling `dev.hold` when the hold level is zero increases the hold level and inhibits graphics display. When calling `dev.flush` clears all pending holds the screen display is refreshed and normal operation is resumed.

This is implemented for the cairo-based X11 types with buffering. When the hold level is positive the ‘watch’ cursor is set on the device’s window.

It is available on the `quartz` device on macOS.

This is implemented for the `windows` device with buffering selected (the default). When the hold level is positive the ‘busy’ cursor is set on the device’s window.

Value

The current level after the change, invisibly. This is 0 on devices where hold levels are not supported.

dev.interactive

Is the Current Graphics Device Interactive?

Description

Test if the current graphics device (or that which would be opened) is interactive.

Usage

```
dev.interactive(orNone = FALSE)

deviceIsInteractive(name = NULL)
```

Arguments

orNone	logical; if TRUE, the function also returns TRUE when <code>.Device == "null device"</code> and <code>getOption("device")</code> is among the known interactive devices.
name	one or more device names as a character vector, or NULL to give the existing list.

Details

The X11 (Unix), windows (Windows) and quartz (macOS, on-screen types only) are regarded as interactive, together with JavaGD (from the package of the same name) and CairoWin and CairoX11 (from package **Cairo**). Packages can add their devices to the list by calling `deviceIsInteractive`.

Value

`dev.interactive()` returns a logical, TRUE if and only if an interactive (screen) device is in use.

`deviceIsInteractive` returns the updated list of known interactive devices, invisibly unless `name = NULL`.

See Also

[Devices](#) for the available devices on your platform.

Examples

```
dev.interactive()
print(deviceIsInteractive(NULL))
```

dev.size

Find Size of Device Surface

Description

Find the dimensions of the device surface of the current device.

Usage

```
dev.size(units = c("in", "cm", "px"))
```

Arguments

units	the units in which to return the value – inches, cm, or pixels (device units).
-------	--

Value

A two-element numeric vector giving width and height of the current device; a new device is opened if there is none, similarly to `dev.new()`.

See Also

The size information in inches can be obtained by `par("din")`, but this provides a way to access it independent of the graphics sub-system in use. Note that `par("din")` is only updated when a new plot is started, whereas `dev.size` tracks the size as an on-screen device is resized.

Examples

```
dev.size("cm")
```

dev2

Copy Graphics Between Multiple Devices

Description

`dev.copy` copies the graphics contents of the current device to the device specified by `which` or to a new device which has been created by the function specified by `device` (it is an error to specify both `which` and `device`). (If recording is off on the current device, there are no contents to copy: this will result in no plot or an empty plot.) The device copied to becomes the current device.

`dev.print` copies the graphics contents of the current device to a new device which has been created by the function specified by `device` and then shuts the new device.

`dev.copy2eps` is similar to `dev.print` but produces an EPSF output file in portrait orientation (`horizontal = FALSE`). `dev.copy2pdf` is the analogue for PDF output.

`dev.control` allows the user to control the recording of graphics operations in a device. If `displaylist` is "inhibit" ("enable") then recording is turned off (on). It is only safe to change this at the beginning of a plot (just before or just after a new page). Initially recording is on for screen devices, and off for print devices.

Usage

```
dev.copy(device, ..., which = dev.next())
dev.print(device = postscript, ...)
dev.copy2eps(...)
dev.copy2pdf(..., out.type = "pdf")
dev.control(displaylist = c("inhibit", "enable"))
```

Arguments

<code>device</code>	A device function (e.g., <code>x11</code> , <code>postscript</code> , ...)
<code>...</code>	Arguments to the device function above: for <code>dev.copy2eps</code> arguments to <code>postscript</code> and for <code>dev.copy2pdf</code> , arguments to <code>pdf</code> . For <code>dev.print</code> , this includes <code>which</code> and by default any <code>postscript</code> arguments.
<code>which</code>	A device number specifying the device to copy to.
<code>out.type</code>	The name of the output device: can be "pdf", or "quartz" (some macOS builds) or "cairo" (Windows and some Unix-alikes, see <code>cairo_pdf</code>).
<code>displaylist</code>	A character string: the only valid values are "inhibit" and "enable".

Details

Note that these functions copy the *device region* and not a plot: the background colour of the device surface is part of what is copied. Most screen devices default to a transparent background, which is probably not what is needed when copying to a device such as `png`.

For `dev.copy2eps` and `dev.copy2pdf`, `width` and `height` are taken from the current device unless otherwise specified. If just one of `width` and `height` is specified, the other is adjusted to preserve the aspect ratio of the device being copied. The default file name is `Rplot.eps` or `Rplot.pdf`, and can be overridden by specifying a `file` argument.

Copying to devices such as `pdf` and `postscript` which need font families pre-specified needs extra care – R is unaware of which families were used in a plot and so they will need to manually specified by the `fonts` argument passed as part of `...`. Similarly, if the device to be copied from was opened with a `family` argument, a suitable `family` argument will need to be included in `...`.

The default for `dev.print` is to produce and print a postscript copy. This will not work unless `options("printcmd")` is set suitably and you have a PostScript printing system: see `postscript` for how to set this up. Windows users may prefer to use `dev.print(win.print)`.

`dev.print` is most useful for producing a postscript print (its default) when the following applies. Unless `file` is specified, the plot will be printed. Unless `width`, `height` and `pointsize` are specified the plot dimensions will be taken from the current device, shrunk if necessary to fit on the paper. (`pointsize` is rescaled if the plot is shrunk.) If `horizontal` is not specified and the plot can be printed at full size by switching its value this is done instead of shrinking the plot region.

If `dev.print` is used with a specified device (even `postscript`) it sets the width and height in the same way as `dev.copy2eps`. This will not be appropriate unless the device specifies dimensions in inches, in particular not for `png`, `jpeg`, `tiff` and `bmp` unless `units = "inches"` is specified.

Value

`dev.copy` returns the name and number of the device which has been copied to.

`dev.print`, `dev.copy2eps` and `dev.copy2pdf` return the name and number of the device which has been copied from.

Note

Most devices (including all screen devices) have a display list which records all of the graphics operations that occur in the device. `dev.copy` copies graphics contents by copying the display list from one device to another device. Also, automatic redrawing of graphics contents following the resizing of a device depends on the contents of the display list.

After the command `dev.control("inhibit")`, graphics operations are not recorded in the display list so that `dev.copy` and `dev.print` will not copy anything and the contents of a device will not be redrawn automatically if the device is resized.

The recording of graphics operations is relatively expensive in terms of memory so the command `dev.control("inhibit")` can be useful if memory usage is an issue.

See Also

`dev.cur` and other `dev.xxx` functions.

Examples

```
## Not run:
x11() # on a Unix-alike
plot(rnorm(10), main = "Plot 1")
dev.copy(device = x11)
mtext("Copy 1", 3)
dev.print(width = 6, height = 6, horizontal = FALSE) # prints it
dev.off(dev.prev())
dev.off()

## End(Not run)
```

dev2bitmap

Graphics Device for Bitmap Files via Ghostscript

Description

bitmap generates a graphics file. dev2bitmap copies the current graphics device to a file in a graphics format.

Usage

```
bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
       units = "in", pointsize, taa = NA, gaa = NA, ...)

dev2bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
          units = "in", pointsize, ...,
          method = c("postscript", "pdf"), taa = NA, gaa = NA)
```

Arguments

file	The output file name, with an appropriate extension.
type	The type of bitmap.
width,height	Dimensions of the display region.
res	Resolution, in dots per inch.
units	The units in which height and width are given. Can be in (inches), px (pixels), cm or mm.
pointsize	The pointsize to be used for text: defaults to something reasonable given the width and height
...	Other parameters passed to postscript or pdf .
method	Should the plot be done by postscript or pdf ?
taa,gaa	Number of bits of antialiasing for text and for graphics respectively. Usually 4 (for best effect) or 2. Not supported on all types.

Details

dev2bitmap works by copying the current device to a `postscript` or `pdf` device, and post-processing the output file using `ghostscript`. `bitmap` works in the same way using a `postscript` device and post-processing the output as 'printing'.

You will need `ghostscript`: the full path to the executable can be set by the environment variable `R_GSCMD`. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike `gs` is used, and on Windows the setting of the environment variable `GSC` is used, otherwise commands `"gswi64c.exe"` then `"gswin32c.exe"` are tried.

The types available will depend on the version of `ghostscript`, but are likely to include `"jpeg"`, `"jpegcmymk"`, `"jpeggray"`, `"tiffcrle"`, `"tiffg3"`, `"tiffg32d"`, `"tiffg4"`, `"tiffgray"`, `"tiffllzw"`, `"tiffpack"`, `"tiff12nc"`, `"tiff24nc"`, `"tiff32nc"`, `"png16"`, `"png16m"`, `"png256"`, `"png48"`, `"pngmono"`, `"pnggray"`, `"pngalpha"`, `"bmp16"`, `"bmp16m"`, `"bmp256"`, `"bmp32b"`, `"bmpgray"`, `"bmpmono"`.

The default type, `"png16m"`, supports 24-bit colour and anti-aliasing. Type `"png256"` uses a palette of 256 colours and could give a more compact representation. Monochrome graphs can use `"pngmono"`, or `"pnggray"` if anti-aliasing is desired. Plots with a transparent background and varying degrees of transparency should use `"pngalpha"`.

Note that for a colour TIFF image you probably want `"tiff24nc"`, which is 8-bit per channel RGB (the most common TIFF format). None of the listed TIFF types support transparency. `"tiff32nc"` uses 8-bit per channel CMYK, which printers might require.

For formats which contain a single image, a file specification like `Rplots%03d.png` can be used: this is interpreted by Ghostscript.

For `dev2bitmap` if just one of `width` and `height` is specified, the other is chosen to preserve the aspect ratio of the device being copied. The main reason to prefer `method = "pdf"` over the default would be to allow semi-transparent colours to be used.

For graphics parameters such as `"cra"` that need to work in pixels, the default resolution of 72dpi is always used.

On Windows only, paths for `file` and `R_GSCMD` which contain spaces are mapped to short names via `shortPathName`.

Value

None.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*. These devices follow the underlying device, so when viewed at the stated `res`:

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is (for the standard Ghostscript setup) URW Nimbus Sans.
- Line widths are as a multiple of 1/96 inch, with no minimum.
- Circle of any radius are allowed.
- Colours are interpreted by the viewing/printing application.

Note

On Windows, Use of `bitmap` will leave a temporary file (with file name starting `Rbit`).

Although using `type = "pdfwrite"` will work for simple plots, it is not recommended. Either use `pdf` to produce PDF directly, or call `ps2pdf -dAutoRotatePages=/None` on the output of `postscript`: that command is optimized to do the conversion to PDF in ways that these functions are not.

See Also

`savePlot`, which for windows and X11 (`type = "cairo"`) provides a simple way to record a PNG record of the current plot.

`postscript`, `pdf`, `png`, `jpeg`, `tiff` and `bmp`.

To display an array of data, see `image`.

devAskNewPage

Prompt before New Page

Description

This function can be used to control (for the current device) whether the user is prompted before starting a new page of output.

Usage

```
devAskNewPage(ask = NULL)
```

Arguments

<code>ask</code>	NULL or a logical value. If <code>TRUE</code> , the user will in future be prompted before a new page of output is started.
------------------	---

Details

If the current device is the null device, this will open a graphics device.

The default argument just returns the current setting and does not change it.

The default value when a device is opened is taken from the setting of `options("device.ask.default")`.

The precise circumstances when the user will be asked to confirm a new page depend on the graphics subsystem. Obviously this needs to be an interactive session. In addition ‘recording’ needs to be in operation, so only when the display list is enabled (see `dev.control`) which it usually is only on a screen device.

Value

The current prompt setting *before* any new setting is applied. Invisibly if `ask` is logical.

See Also

`plot.new`, `grid.newpage`

Description

The following graphics devices are currently available:

windows: On Windows only, the graphics device for Windows (on screen, to printer and to Windows metafile).

pdf: Write PDF graphics commands to a file.

postscript: Writes PostScript graphics commands to a file.

xfig: Device for XFig graphics file format. (Of historical interest only, deprecated in R 4.4.0.)

bitmap: bitmap pseudo-device via Ghostscript (if available).

pictex: Writes TeX/PicTeX graphics commands to a file (of historical interest only, deprecated in R 4.4.0).

The following devices will be functional if R was compiled to use them (they exist but will return with a warning on other systems):

cairo_pdf, **cairo_ps**: PDF and PostScript devices based on cairo graphics.

svg: SVG device based on cairo graphics

png: PNG bitmap device

jpeg: JPEG bitmap device

bmp: BMP bitmap device

tiff: TIFF bitmap device

On Unix-alikes (including macOS) only:

X11: The graphics device for the X11 windowing system

quartz: The graphics device for the macOS native Quartz 2d graphics system. (This is only functional on macOS where it can be used from the R .app GUI and from the command line: but it will display on the local screen even for a remote session.)

Details

If no device is open, calling any high-level graphics function will cause a device to be opened. Which device is determined by `options("device")` which is initially set as the most appropriate for each platform: a screen device for most interactive use and `pdf` (or the setting of `R_DEFAULT_DEVICE`) otherwise. The exception is interactive use under Unix if no screen device is known to be available, when `pdf()` is used.

It is possible for an R package (or an R front-end such as RStudio) to provide further graphics devices and several packages on CRAN do so. These include devices outputting SVG (**svglite** and PGF/TikZ (**tikzDevice**, TeX-based graphics, see <https://pgf.sourceforge.net/>).

```
## Not run:
## open the default screen device on this platform if no device is
## open
if(dev.cur() == 1) dev.new()

## End(Not run)
```

embedFonts

Embed Fonts in PostScript and PDF

Description

Runs Ghostscript to process a PDF or PostScript file and embed all fonts in the file.

Use `embedGlyphs()` if you have drawn typeset glyphs (see [glyphInfo](#)), which is only relevant for PDF files.

Usage

```
embedFonts(file, format, outfile = file,
           fontpaths = character(), options = character())

embedGlyphs(file, glyphInfo, outfile = file, options = character())
```

Arguments

<code>file</code>	a character string giving the name of the original file.
<code>format</code>	the format for the new file (with fonts embedded) given as the name of a Ghostscript output device. If not specified, it is guessed from the suffix of <code>file</code> .
<code>outfile</code>	the name of the new file (with fonts embedded).
<code>fontpaths</code>	a character vector giving directories that Ghostscript will search for fonts.
<code>options</code>	a character vector containing further options to Ghostscript.
<code>glyphInfo</code>	typeset glyph information produced by <code>glyphInfo()</code> , or a list of the same.

Details

This function is not necessary if you just use the standard default fonts for PostScript and PDF output.

If you use a special font, this function is useful for embedding that font in your PostScript or PDF document so that it can be shared with others without them having to install your special font (provided the font licence allows this).

If the special font is not installed for Ghostscript, you will need to tell Ghostscript where the font is, using something like `options="-sFONTPATH=path/to/font"`.

You will need `ghostscript`: the full path to the executable can be set by the environment variable `R_GSCMD`. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike `"gs"` is used, and on Windows the setting of the environment variable `GSC` is used, otherwise commands `"gswi64c.exe"` then `"gswin32c.exe"` are tried.

The format is by default `"ps2write"`, when the original file has a `.ps` or `.eps` suffix, or `"pdfwrite"` when the original file has a `.pdf` suffix. For versions of Ghostscript before 9.10, `format = "pswrite"` or `format = "epswrite"` can be used: as from 9.14 `format = "eps2write"` is also available. If an invalid device is given, the error message will list the available devices.

Note that Ghostscript may do font substitution, so the font embedded may differ from that specified in the original file.

Some other options which can be useful (see your Ghostscript documentation) are `'-dMaxSubsetPct=100'`, `'-dSubsetFonts=true'` and `'-dEmbedAllFonts=true'`.

`embedGlyphs()` is recommended for `pdf()` files that contain typeset glyphs (see [glyphInfo](#)), but it will only work for TrueType fonts.

Value

The shell command used to invoke Ghostscript is returned invisibly. This may be useful for debugging purposes as you can run the command by hand in a shell to look for problems.

extendrange

Extend a Numerical Range by a Small Percentage

Description

Extends a numerical range by a small percentage, i.e., fraction, *on both sides*.

Usage

```
extendrange(x, r = range(x, na.rm = TRUE), f = 0.05)
```

Arguments

<code>x</code>	numeric vector; not used if <code>r</code> is specified.
<code>r</code>	numeric vector of length 2; defaults to the <code>range</code> of <code>x</code> .
<code>f</code>	positive number(s) specifying the fraction by which the range should be extended. If longer than one, <code>f[1]</code> is used on the left, and <code>f[2]</code> on the right.

Value

A numeric vector of length 2, $r + c(-f1, f2) * \text{diff}(r)$, where `f1` is `f[1]` and `f2` is `f[2]` or `f` if it is of length one.

See Also

`range`; `pretty` which can be considered a sophisticated extension of `extendrange`.

Examples

```
x <- 1:5
(r <- range(x))           # 1      5
extendrange(x)            # 0.8    5.2
extendrange(x, f= 0.01)  # 0.96   5.04

## extend more to the right:
extendrange(x, f=c(.01,.03)) # 0.96 5.12

## Use 'r' if you have it already:
stopifnot(identical(extendrange(r = r),
                    extendrange(x)))
```

<code>getGraphicsEvent</code>	<i>Wait for a mouse or keyboard event from a graphics window</i>
-------------------------------	--

Description

This function waits for input from a graphics window in the form of a mouse or keyboard event.

Usage

```
getGraphicsEvent(prompt = "Waiting for input",
                 onMouseDown = NULL, onMouseMove = NULL,
                 onMouseUp = NULL, onKeybd = NULL,
                 onIdle = NULL,
                 consolePrompt = prompt)
setGraphicsEventHandlers(which = dev.cur(), ...)
getGraphicsEventEnv(which = dev.cur())
setGraphicsEventEnv(which = dev.cur(), env)
```

Arguments

<code>prompt</code>	prompt to be displayed to the user in the graphics window
<code>onMouseDown</code>	a function to respond to mouse clicks
<code>onMouseMove</code>	a function to respond to mouse movement
<code>onMouseUp</code>	a function to respond to mouse button releases
<code>onKeybd</code>	a function to respond to key presses
<code>onIdle</code>	a function to call when no events are pending
<code>consolePrompt</code>	prompt to be displayed to the user in the console
<code>which</code>	which graphics device does the call apply to?
<code>...</code>	items including handlers to be placed in the event environment
<code>env</code>	an environment to be used as the event environment

Details

These functions allow user input from some graphics devices (currently only the `windows()`, `X11(type = "Xlib")` and `X11(type = "cairo")` screen displays in base R). Event handlers may be installed to respond to events involving the mouse or keyboard.

The functions are related as follows. If any of the first six arguments to `getGraphicsEvent` are given, then it uses those in a call to `setGraphicsEventHandlers` to replace any existing handlers in the current device. This is for compatibility with pre-2.12.0 R versions. The current normal way to set up event handlers is to set them using `setGraphicsEventHandlers` or `setGraphicsEventEnv` on one or more graphics devices, and then use `getGraphicsEvent()` with no arguments to retrieve event data. `getGraphicsEventEnv()` may be used to save the event environment for use later.

The names of the arguments in `getGraphicsEvent` are special. When handling events, the graphics system will look through the event environment for functions named `onMouseDown`, `onMouseMove`, `onMouseUp`, `onKeybd`, and `onIdle`, and use them as event handlers. It will use `prompt` for a label on the graphics device. Two other special names are `which`, which will identify the graphics device, and `result`, where the result of the last event handler will be stored before being returned by `getGraphicsEvent()`.

The mouse event handlers should be functions with header `function(buttons, x, y)`. The coordinates `x` and `y` will be passed to mouse event handlers in device independent coordinates (i.e., the lower left corner of the window is `(0, 0)`, the upper right is `(1, 1)`). The `buttons` argument will be a vector listing the buttons that are pressed at the time of the event, with 0 for left, 1 for middle, and 2 for right.

The keyboard event handler should be a function with header `function(key)`. A single element character vector will be passed to this handler, corresponding to the key press. Shift and other modifier keys will have been processed, so `shift-a` will be passed as `"A"`. The following special keys may also be passed to the handler:

- Control keys, passed as `"Ctrl-A"`, etc.
- Navigation keys, passed as one of `"Left"`, `"Up"`, `"Right"`, `"Down"`, `"PgUp"`, `"PgDn"`, `"End"`, `"Home"`
- Edit keys, passed as one of `"Ins"`, `"Del"`
- Function keys, passed as one of `"F1"`, `"F2"`, ...

The idle event handler `onIdle` should be a function with no arguments. If the function is undefined or `NULL`, then R will typically call a system function which (efficiently) waits for the next event to appear on a file handle. Otherwise, the idle event handler will be called whenever the event queue of the graphics device was found to be empty, i.e. in an infinite loop. This feature is intended to allow animations to respond to user input, and could be CPU-intensive. Currently, `onIdle` is only implemented for `X11()` devices.

Note that calling `Sys.sleep()` is not recommended within an idle handler - `Sys.sleep()` removes pending graphics events in order to allow users to move, close, or resize windows while it is executing. Events such as mouse and keyboard events occurring during `Sys.sleep()` are lost, and currently do not trigger the event handlers registered via `getGraphicsEvent` or `setGraphicsEventHandlers`.

The event handlers are standard R functions, and will be executed as though called from the event environment.

In an interactive session, events will be processed until

- one of the event handlers returns a non-`NULL` value which will be returned as the value of `getGraphicsEvent`, or
- the user interrupts the function from the console.

Value

When run interactively, `getGraphicsEvent` returns a non-`NULL` value returned from one of the event handlers. In a non-interactive session, `getGraphicsEvent` will return `NULL` immediately. It will also return `NULL` if the user closes the last window that has graphics handlers.

`getGraphicsEventEnv` returns the current event environment for the graphics device, or `NULL` if none has been set.

`setGraphicsEventEnv` and `setGraphicsEventHandlers` return the previous event environment for the graphics device.

par(savepar)

## End(Not run)

```

glyphInfo

Describe a Set of Typeset Glyphs

Description

Create an object that contains information about typeset glyphs. This includes glyph identifiers, glyph locations, font, colour and rotation information, and metric information.

Usage

```
glyphInfo(id, x, y, font, size, fontList,
```

```

width, height, hAnchor, vAnchor,
col=NA, rot=0)

glyphFont(file, index, family, weight, style, PSname=NA, variations=NULL)
glyphFontVariation(...)
glyphFontList(...)
glyphAnchor(value, label)
glyphWidth(w, label="width", left="left")
glyphHeight(h, label="height", bottom="bottom")
glyphWidthLeft(w, label)
glyphHeightBottom(h, label)
glyphJust(just, ...)
## S3 method for class 'GlyphJust'
glyphJust(just, ...)
## S3 method for class 'character'
glyphJust(just, ...)
## S3 method for class 'numeric'
glyphJust(just, which=NULL, ...)

```

Arguments

<code>id</code>	Numeric vector of glyph identifiers (index of glyph within font file).
<code>x, y</code>	Numeric locations of glyphs in (big) points (1/72 inches).
<code>font</code>	Integer index into <code>fontList</code> .
<code>size</code>	Numeric size of glyphs (in points).
<code>fontList</code>	List of glyph fonts, as generated by <code>glyphFont()</code> .
<code>width</code>	Overall width of glyphs. Can be a single numeric value, but can also be the result from a call to <code>glyphWidth()</code> .
<code>height</code>	Overall height of glyphs. Can be a single numeric value, but can also be the result from a call to <code>glyphHeight()</code> .
<code>hAnchor</code>	Horizontal anchors for justifying glyphs relative to the (x, y) location. Can be a single numeric value (against which to "left" justify), but can also be result from a call to <code>glyphAnchor()</code> .
<code>vAnchor</code>	Vertical anchors for justifying glyphs relative to the (x, y) location. Can be a single numeric value (against which to "bottom" justify), but can also be result from a call to <code>glyphAnchor()</code> .
<code>col</code>	An R colour value for each glyph. Can be NA.
<code>rot</code>	The angle to rotate each glyph.
<code>file</code>	Character path to font file.
<code>index</code>	Numeric index of font within font file.
<code>family</code>	Character name of font family.
<code>weight</code>	Numeric weight of glyphs (400 is normal, 700 is bold).
<code>style</code>	Character style of glyphs ("normal", "italic", or "oblique").
<code>PSname</code>	The PostScript name for each font. Can be NA.
<code>variations</code>	Axis coordinate settings for variable fonts. Either NULL, or a call to <code>glyphFontVariation()</code> , or a named vector, or a named list.
<code>value, w, h</code>	A numeric value.

<code>label, left, bottom</code>	A character value.
<code>just</code>	A justification value. Either a character value like "left" or a numeric value like 0.
<code>which</code>	When <code>x</code> is numeric, a character value identifying which width metric the numeric value is relative to.
<code>...</code>	For <code>glyphFontList()</code> , one or more <code>glyphFont()</code> s. For <code>glyphFontVar()</code> , one or more named numeric values (see Details). Otherwise, further arguments passed to other methods.

Details

Multiple anchors can be specified so as to allow different character-based justifications of the glyphs relative to the (x, y) location. Horizontal anchors with labels "left", "centre", and "right" are required. It is possible to specify a single numeric `hAnchor`, which is treated as the "left" anchor, or a single anchor with label "left", in which case the other required anchors will be calculated based on the required width of the glyphs (see below). Vertical anchors with labels "bottom", "centre", and "top" are required. It is possible to specify a single numeric `vAnchor`, which is treated as the "bottom" anchor, or a single anchor with label "bottom", in which case the other required anchors will be calculated based on the required height of the glyphs (see below). An example of a non-required anchor is a vertical anchor with the label "baseline" so that the glyphs can be placed with their baseline at the `y` location.

Multiple widths and heights can be specified so as to allow different numeric-based justifications of the glyphs relative to the (x, y) location, e.g., 0 for left-justification and 1 for right-justification, but with any value in between or even outside those limits also possible. A width with label "width", relative to the "left" horizontal anchor, is required, but if a single numeric value is given, that is assumed to be the required width. A height with label "height", relative to the "bottom" vertical anchor is required, but if a single numeric value is given, that is assumed to be the required height. An example of a non-required width is a "tight" width that is relative to a "left-bearing" horizontal anchor, so that the glyphs can be justified relative to a bounding box around the glyph ink, rather than a bounding box that includes left and right bearings.

`glyphWidthLeft()` and `glyphWidthHeight()` provide an API for code that needs to access the relevant anchors for width and height metrics.

`glyphFontVariation()` accepts arguments of the form `wght=100`. Every argument should be named, each name should be 4 ASCII characters long, each name should be either one of the standard axes (`wght`, `slnt`, `wdth`, `ital`, `opsz`), in lowercase, otherwise (if a custom axis) in uppercase. Every argument value should be numeric.

Value

The result from `glyphInfo()` is an "RGlyphInfo" object, essentially a data frame with each row containing `id`, `location`, `font`, `colour` and `rotation` for a glyph. The metric information (widths and anchors) are stored as attributes of the data frame.

`glyphAnchor()`, `glyphWidth()`, and `glyphHeight()` return values that can be used to specify `width`, `height`, `hAnchor`, and `vAnchor` values to `glyphInfo()`.

Warning

Any glyph with NA in any of `id`, `x`, `y`, `size` or `rot` is silently dropped.

gray

Gray Level Specification

Description

Create a vector of colors from a vector of gray levels.

Usage

```
gray(level, alpha)
grey(level, alpha)
```

Arguments

level	a vector of desired gray levels between 0 and 1; zero indicates "black" and one indicates "white".
alpha	the opacity, if specified.

Details

The values returned by `gray` can be used with a `col=` specification in graphics functions or in [par](#).

`grey` is an alias for `gray`.

Value

A vector of colors of the same length as `level`.

See Also

[rainbow](#), [hsv](#), [hcl](#), [rgb](#).

Examples

```
gray(0:8 / 8)
```

gray.colors

Gray Color Palette

Description

Create a vector of `n` gamma-corrected gray colors.

Usage

```
gray.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha, rev = FALSE)
grey.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha, rev = FALSE)
```

Arguments

n	the number of gray colors (≥ 1) to be in the palette.
start	starting gray level in the palette (should be between 0 and 1 where zero indicates "black" and one indicates "white").
end	ending gray level in the palette.
gamma	the gamma correction.
alpha	the opacity, if specified.
rev	logical indicating whether the ordering of the colors should be reversed.

Details

The function `gray.colors` chooses a series of n gamma-corrected gray levels between `start` and `end`: `seq(start^gamma, end^gamma, length = n)^(1/gamma)`. The returned palette contains the corresponding gray colors. This palette is used in `barplot.default`.

`grey.colors` is an alias for `gray.colors`.

Value

A vector of n gray colors.

See Also

`gray`, `rainbow`, `palette`.

Examples

```
require(graphics)

pie(rep(1, 12), col = gray.colors(12))
barplot(1:12, col = gray.colors(12))
```

Description

Report versions of third-party graphics software available on the current platform for R's graphics.

Usage

```
grSoftVersion()
```

Value

A named character vector containing at least the elements

<code>cairo</code>	the version of <code>cairographics</code> in use, or "" if <code>cairographics</code> is not available.
<code>cairoFT</code>	the FreeType/FontConfig versions if <code>cairographics</code> is using those libraries directly (not <i>via</i> <code>pango</code>); otherwise, "". Earlier versions of R returned "yes" rather than the versions. The FontConfig version is determined when R is built.
<code>pango</code>	the version of <code>pango</code> in use, or "" if <code>pango</code> is not available.

It may also contain the versions of third-party software used by the standard (on Windows), or X11-based (on Unix-alikes) bitmap devices:

<code>libpng</code>	the version of <code>libpng</code> in use, or "" if not available.
<code>jpeg</code>	the version of the JPEG headers used for compilation, or "" if JPEG support was not compiled in.
<code>libtiff</code>	the version of <code>libtiff</code> in use, or "" if not available.

It is conceivable but unlikely that the `cairo`-based bitmap devices will use different versions linked *via* `cairographics`, especially `png (type = "cairo-png")`.

On macOS, if available, the Quartz-based devices will use the system versions of these libraries rather than those reported here.

Unless otherwise stated the reported version is that of the (possibly dynamically-linked) library in use at runtime.

Note that `libjpeg-turbo` as used on some Linux distributions reports its version as "6.2", the IJG version from which it forked.

See Also

[extSoftVersion](#) for versions of non-graphics software.

Examples

```
grSoftVersion()
```

HCL Color Specification

Description

Create a vector of colors from vectors specifying hue, chroma and luminance.

Usage

```
hcl(h = 0, c = 35, l = 85, alpha, fixup = TRUE)
```

Arguments

<code>h</code>	The hue of the color specified as an angle in the range [0,360]. 0 yields red, 120 yields green 240 yields blue, etc.
<code>c</code>	The chroma of the color. The upper bound for chroma depends on hue and luminance.
<code>l</code>	A value in the range [0,100] giving the luminance of the colour. For a given combination of hue and chroma, only a subset of this range is possible.
<code>alpha</code>	numeric vector of values in the range [0, 1] for alpha transparency channel (0 means transparent and 1 means opaque).
<code>fixup</code>	a logical value which indicates whether the resulting RGB values should be corrected to ensure that a real color results. if <code>fixup</code> is <code>FALSE</code> RGB components lying outside the range [0,1] will result in an NA value.

Details

This function corresponds to polar coordinates in the CIE-LUV color space. Steps of equal size in this space correspond to approximately equal perceptual changes in color. Thus, `hcl` can be thought of as a perceptually based version of `hsv`.

The function is primarily intended as a way of computing colors for filling areas in plots where area corresponds to a numerical value (pie charts, bar charts, mosaic plots, histograms, etc). Choosing colors which have equal chroma and luminance provides a way of minimising the irradiation illusion which would otherwise produce a misleading impression of how large the areas are.

The default values of chroma and luminance make it possible to generate a full range of hues and have a relatively pleasant pastel appearance.

The RGB values produced by this function correspond to the sRGB color space used on most PC computer displays. There are other packages which provide more general color space facilities.

Semi-transparent colors ($0 < \text{alpha} < 1$) are supported only on some devices: see `rgb`.

Value

A vector of character strings which can be used as color specifications by R graphics functions.

Missing or infinite values of any of `h`, `c`, `l` result in NA: such values of `alpha` are taken as 1 (opaque).

Note

At present there is no guarantee that the colours rendered by R graphics devices will correspond to their sRGB description. It is planned to adopt sRGB as the standard R color description in future.

# Single Color
hist(stats::rnorm(1000), col = hcl(240))

## Exploring the hcl() color space {in its mapping to R's sRGB colors}:
demo(hclColors)
```

Description

If the `family` graphical parameter (see `par`) has been set to one of the Hershey fonts (see ‘Details’) Hershey vector fonts are used to render text.

When using the `text` and `contour` functions Hershey fonts may be selected via the `vfont` argument, which is a character vector of length 2 (see ‘Details’ for valid values). This allows Cyrillic to be selected, which is not available via the font families.

Usage

```
Hershey
```

Details

The Hershey fonts have two advantages:

1. vector fonts describe each character in terms of a set of points; R renders the character by joining up the points with straight lines. This intimate knowledge of the outline of each character means that R can arbitrarily transform the characters, which can mean that the vector fonts look better for rotated text.
2. this implementation was adapted from the GNU libplot library which provides support for non-ASCII and non-English fonts. This means that it is possible, for example, to produce weird plotting symbols and Japanese characters.

Drawback:

You cannot use mathematical expressions (`plotmath`) with Hershey fonts.

The Hershey characters are organised into a set of fonts. A particular font is selected by specifying one of the following font families via `par(family)` and specifying the desired font face (`plain`, `bold`, `italic`, `bold-italic`) via `par(font)`.

family	faces available
"HersheySerif"	plain, bold, italic, bold-italic
"HersheySans"	plain, bold, italic, bold-italic
"HersheyScript"	plain, bold
"HersheyGothicEnglish"	plain
"HersheyGothicGerman"	plain
"HersheyGothicItalian"	plain
"HersheySymbol"	plain, bold, italic, bold-italic
"HersheySansSymbol"	plain, italic

In the `vfont` specification for the `text` and `contour` functions, the Hershey font is specified by a `typeface` (e.g., `serif` or `sans serif`) and a `fontindex` or ‘style’ (e.g., `plain` or `italic`). The first element of `vfont` specifies the `typeface` and the second element specifies the `fontindex`. The first table produced by `demo(Hershey)` shows the character a produced by each of the different fonts.

The available `typeface` and `fontindex` values are available as list components of the variable `Hershey`. The allowed pairs for (`typeface`, `fontindex`) are:

<code>serif</code>	<code>plain</code>
<code>serif</code>	<code>italic</code>

serif	bold
serif	bold italic
serif	cyrillic
serif	oblique cyrillic
serif	EUC
sans serif	plain
sans serif	italic
sans serif	bold
sans serif	bold italic
script	plain
script	italic
script	bold
gothic englisho	plain
gothic german	plain
gothic italian	plain
serif symbol	plain
serif symbol	italic
serif symbol	bold
serif symbol	bold italic
sans serif symbol	plain
sans serif symbol	italic

and the indices of these are available as `Hershey$allowed`.

Escape sequences: The string to be drawn can include escape sequences, which all begin with a ‘\’. When `R` encounters a ‘\’, rather than drawing the ‘\’, it treats the subsequent character(s) as a coded description of what to draw.

One useful escape sequence (in the current context) is of the form: ‘\123’. The three digits following the ‘\’ specify an octal code for a character. For example, the octal code for `p` is 160 so the strings “`p`” and “\160” are equivalent. This is useful for producing characters when there is not an appropriate key on your keyboard.

The other useful escape sequences all begin with ‘\\’. These are described below. Remember that backslashes have to be doubled in `R` character strings, so they need to be entered with *four* backslashes.

Symbols: an entire string of Greek symbols can be produced by selecting the `HersheySymbol` or `HersheySansSymbol` family or the `Serif Symbol` or `Sans Serif Symbol` typeface. To allow Greek symbols to be embedded in a string which uses a non-symbol typeface, there are a set of symbol escape sequences of the form ‘\\ab’. For example, the escape sequence ‘*a’ produces a Greek alpha. The second table in `demo(Hershey)` shows all of the symbol escape sequences and the symbols that they produce.

ISO Latin-1: further escape sequences of the form ‘\\ab’ are provided for producing ISO Latin-1 characters. Another option is to use the appropriate octal code. The (non-ASCII) ISO Latin-1 characters are in the range 241...377. For example, ‘\366’ produces the character `o` with an umlaut. The third table in `demo(Hershey)` shows all of the ISO Latin-1 escape sequences. These characters can be used directly. (Characters not in Latin-1 are replaced by a dot.)

Several characters are missing, `c-cedilla` has no cedilla and ‘sharp `s`’ (‘U+00DF’, also known as ‘esszett’) is rendered as `ss`.

Special Characters: a set of characters are provided which do not fall into any standard font. These can only be accessed by escape sequence. For example, ‘\\LI’ produces the zodiac sign for Libra, and ‘\\JU’ produces the astronomical sign for Jupiter. The fourth table in `demo(Hershey)` shows all of the special character escape sequences.

Cyrillic Characters: cyrillic characters are implemented according to the K018-R encoding, and can be used directly in such a locale using the Serif typeface and Cyrillic (or Oblique Cyrillic) fontindex. Alternatively they can be specified via an octal code in the range 300 to 337 for lower case characters or 340 to 377 for upper case characters. The fifth table in `demo(Hershey)` shows the octal codes for the available Cyrillic characters.

Cyrillic has to be selected via a `("serif", fontindex)` pair rather than via a font family.

Japanese Characters: 83 Hiragana, 86 Katakana, and 603 Kanji characters are implemented according to the EUC-JP (Extended Unix Code) encoding. Each character is identified by a unique hexadecimal code. The Hiragana characters are in the range 0x2421 to 0x2473, Katakana are in the range 0x2521 to 0x2576, and Kanji are (scattered about) in the range 0x3021 to 0x6d55.

When using the Serif typeface and EUC fontindex, these characters can be produced by a *pair* of octal codes. Given the hexadecimal code (e.g., 0x2421), take the first two digits and add 0x80 and do the same to the second two digits (e.g., 0x21 and 0x24 become 0xa4 and 0xa1), then convert both to octal (e.g., 0xa4 and 0xa1 become 244 and 241). For example, the first Hiragana character is produced by `'\244\241'`.

It is also possible to use the hexadecimal code directly. This works for all non-EUC fonts by specifying an escape sequence of the form `'\\#J1234'`. For example, the first Hiragana character is produced by `'\\#J2421'`.

The Kanji characters may be specified in a third way, using the so-called "Nelson Index", by specifying an escape sequence of the form `'\\#N1234'`. For example, the (obsolete) Kanji for 'one' is produced by `'\\#N0001'`.

`demo(Japanese)` shows the available Japanese characters.

Raw Hershey Glyphs: all of the characters in the Hershey fonts are stored in a large array. Some characters are not accessible in any of the Hershey fonts. These characters can only be accessed via an escape sequence of the form `'\\#H1234'`. For example, the fleur-de-lys is produced by `'\\#H0746'`. The sixth and seventh tables of `demo(Hershey)` shows all of the available raw glyphs.

Examples

```
Hershey
```

```
## for tables of examples, see demo(Hershey)
```

Description

Create a vector of colors from vectors specifying hue, saturation and value.

Usage

```
hsv(h = 1, s = 1, v = 1, alpha)
```

Arguments

<code>h, s, v</code>	numeric vectors of values in the range $[0, 1]$ for ‘hue’, ‘saturation’ and ‘value’ to be combined to form a vector of colors. Values in shorter arguments are recycled.
<code>alpha</code>	numeric vector of values in the range $[0, 1]$ for alpha transparency channel (0 means transparent and 1 means opaque).

Details

Semi-transparent colors ($0 < \text{alpha} < 1$) are supported only on some devices: see [rgb](#).

Value

This function creates a vector of colors corresponding to the given values in HSV space. The values returned by `hsv` can be used with a `col=` specification in graphics functions or in `par`.

See Also

[hcl](#) for a perceptually based version of `hsv()`, [rgb](#) and [rgb2hsv](#) for RGB to HSV conversion; [rainbow](#), [gray](#).

Examples

```
require(graphics)

hsv(.5, .5, .5)

## Red tones:
n <- 20; y <- -sin(3*pi*((1:n)-1/2)/n)
op <- par(mar = rep(1.5, 4))
plot(y, axes = FALSE, frame.plot = TRUE,
      xlab = "", ylab = "", pch = 21, cex = 30,
      bg = rainbow(n, start = .85, end = .1),
      main = "Red tones")
par(op)
```

Description

The implementation of Hershey vector fonts provides a large number of Japanese characters (Hiragana, Katakana, and Kanji).

Details

Without keyboard support for typing Japanese characters, the only way to produce these characters is to use special escape sequences: see [Hershey](#).

For example, the Hiragana character for the sound ‘ka’ is produced by ‘\\#J242b’ and the Katakana character for this sound is produced by ‘\\#J252b’. The Kanji ideograph for "one" is produced by ‘\\#J306c’ or ‘\\#N0001’.

The output from `demo(Japanese)` shows tables of the escape sequences for the available Japanese characters.

text(8, 6, "Kanji")
text(8, 8, "English")
```

make.rgb

Create colour spaces

Description

These functions specify colour spaces for use in [convertColor](#).

Usage

```
make.rgb(red, green, blue, name = NULL, white = "D65",
         gamma = 2.2)
```

```
colorConverter(toXYZ, fromXYZ, name, white = NULL, vectorized = FALSE)
```

Arguments

<code>red, green, blue</code>	Chromaticity (xy or xyY) of RGB primaries
<code>name</code>	Name for the colour space
<code>white</code>	Character string specifying the reference white (see 'Details').
<code>gamma</code>	Display gamma (nonlinearity). A positive number or the string "sRGB"
<code>fromXYZ</code>	Function to convert from XYZ tristimulus coordinates to this space
<code>toXYZ</code>	Function to convert from this space to XYZ tristimulus coordinates.
<code>vectorized</code>	Whether <code>fromXYZ</code> and <code>toXYZ</code> are vectorized internally to handle input color matrices.

Details

An RGB colour space is defined by the chromaticities of the red, green and blue primaries. These are given as vectors of length 2 or 3 in xyY coordinates (the Y component is not used and may be omitted). The chromaticities are defined relative to a reference white, which must be one of the CIE standard illuminants: "A", "B", "C", "D50", "D55", "D60", "E" (usually "D65").

The display gamma is most commonly 2.2, though 1.8 is used for Apple RGB. The sRGB standard specifies a more complicated function that is close to a gamma of 2.2; `gamma = "sRGB"` uses this function.

Colour spaces other than RGB can be specified directly by giving conversions to and from XYZ tristimulus coordinates. The functions should take two arguments. The first is a vector giving the coordinates for one colour. The second argument is the reference white. If a specific reference white is included in the definition of the colour space (as for the RGB spaces) this second argument should be ignored and may be . . .

As of R 3.6.0 the built in color converters along with `convertColor` were vectorized to process three column color matrices in one call, instead of row by row via `apply`. In order to maintain backwards compatibility, `colorConverter` wraps `fromXYZ` and `toXYZ` in a `apply` loop in case they do not also support matrix inputs. If the `fromXYZ` and `toXYZ` functions you are using operate correctly on the whole color matrix at once instead of row by row, you can set `vectorized=TRUE` for a performance improvement.

Value

An object of class `colorConverter`

(cc <- round(convertColor(as.matrix(hex), from = hexcolor, to = "sRGB",
  scale.in = NULL, scale.out = 255)))
stopifnot(cc == cols)

## Internally vectorized version of hexcolor, notice the use
## of `vectorized = TRUE`:

hexcolorv <- colorConverter(toXYZ = function(hex, ...) {
  rgb <- t(col2rgb(hex))/255
  colorspace$sRGB$toXYZ(rgb, ...) },
  fromXYZ = function(xyz, ...) {
    rgb <- colorspace$sRGB$fromXYZ(xyz, ...)
    rgb <- round(rgb, 5)
    oob <- pmin(rgb[,1], rgb[,2], rgb[,3]) < 0 |
      pmax(rgb[,1], rgb[,2], rgb[,3]) > 0
    res <- rep(NA_character_, nrow(rgb))
    res[!oob] <- rgb(rgb[!oob,,drop=FALSE]),
    white = "D65", name = "#rrgbbb",
    vectorized=TRUE)
(ccv <- round(convertColor(as.matrix(hex), from = hexcolor, to = "sRGB",
  scale.in = NULL, scale.out = 255)))
stopifnot(ccv == cols)
```

msgWindow

Manipulate a Window

Description

On Windows, only, msgWindow sends a message to manipulate the specified screen device's window. With argument which = -1 it applies to the GUI console (which only accepts the first three actions).

Usage

```
msgWindow(type = c("minimize", "restore", "maximize",
  "hide", "recordOn", "recordOff"),
  which = dev.cur())
```

Arguments

type	action to be taken.
which	a device number, or -1.

See Also

n2mfrow

Compute Default mfrow From Number of Plots

Description

Easy setup for plotting multiple figures (in a rectangular layout) on one page. This computes a sensible default for [par](#)(mfrow).

Usage

```
n2mfrow(nr.plots, asp = 1)
```

Arguments

nr.plots	integer; the number of plot figures you'll want to draw.
asp	positive number; the target aspect ratio (columns / rows) in the output. Was implicitly hardwired to 1; because of that and back compatibility, there is a somewhat discontinuous behavior when varying asp around 1, for nr.plots <= 12.

Value

A length-two integer vector (nr, nc) giving the positive number of rows and columns, fulfilling $nr * nc \geq nr.plots$, and currently, for $asp = 1$, $nr \geq nc \geq 1$.

Note

Conceptually, this is a quadratic integer optimization problem, with inequality constraints $nr \geq 1$, $nc \geq 1$, and $nr.plots \geq nr * nc$ (and possibly $nr \geq asp * nc$), and *two* objective functions which would have to be combined via a tuning weight, say w , to, e.g., $(nr.plots - nr * nc) + w|nr/nc - asp|$.

The current algorithm is simple and not trying to solve one of these optimization problems.

Author(s)

Martin Maechler; suggestion of asp by Michael Chirico.

```
require(graphics)

n2mfrow(8) # 3 x 3

n <- 5 ; x <- seq(-2, 2, length.out = 51)
## suppose now that 'n' is not known {inside function}
op <- par(mfrow = n2mfrow(n))
for (j in 1:n)
  plot(x, x^j, main = substitute(x^ exp, list(exp = j)), type = "l",
       col = "blue")

sapply(1:14, n2mfrow)
sapply(1:14, n2mfrow, asp=16/9)
```

nclass

Compute the Number of Classes for a Histogram

Description

Compute the number of classes for a histogram, notably `hist()`.

Usage

```
nclass.Sturges(x)
nclass.scott(x)
nclass.FD(x, digits = 5)
```

Arguments

<code>x</code>	a data vector.
<code>digits</code>	number of <i>significant</i> digits to keep when rounding <code>x</code> before the IQR computation; see ‘Details’ below.

Details

`nclass.Sturges` uses Sturges’ formula, implicitly basing bin sizes on the range of the data.

`nclass.scott` uses Scott’s choice for a normal distribution based on the estimate of the standard error, unless that is zero where it returns 1.

`nclass.FD` uses the Freedman-Diaconis choice based on the inter-quartile range ([IQR](#)(`signif(x, digits)`)) unless that’s zero where it uses increasingly more extreme symmetric quantiles up to `c(1,511)/512` and if that difference is still zero, reverts to using Scott’s choice. The default of `digits = 5` was chosen after a few experiments, but may be too low for some situations, see [PR#17274](#).

Value

The suggested number of classes.

onePt <- rep(1, 11)
NC(onePt) # no longer gives NaN
```

palette

Set or View the Graphics Palette

Description

View or manipulate the color palette which is used when `col=` has a numeric index and supporting functions.

Usage

```
palette(value)
palette.pals()
palette.colors(n = NULL, palette = "Okabe-Ito", alpha, recycle = FALSE,
  names = FALSE)
```

Arguments

<code>value</code>	an optional character vector specifying a new palette (see Details).
<code>n</code>	the number of colors to select from a palette. The default <code>NULL</code> selects all colors of the given palette.
<code>palette</code>	a valid palette name (one of <code>palette.pals()</code>). The name is matched to the list of available palettes, ignoring upper vs. lower case, spaces, dashes, etc. in the matching.
<code>alpha</code>	an alpha-transparency level in the range <code>[0,1]</code> (0 means transparent and 1 means opaque).
<code>recycle</code>	logical indicating what happens in case <code>n > length(palette())</code> . By default (<code>recycle = FALSE</code>), the result is as for <code>n = NULL</code> , but with a warning.
<code>names</code>	logical indicating whether a named vector of colors should be returned or not (provided that the palette has any names for its colors).

Details

The `palette()` function gets or sets the current palette, the `palette.pals()` function lists the available predefined palettes, and the `palette.colors()` function selects colors from the predefined palettes.

The color palette and referring to colors by number (see e.g. `par`) was provided for compatibility with S. R extends and improves on the available set of palettes.

If `value` has length 1, it is taken to be the name of a built-in color palette. The available palette names are returned by `palette.pals()`. It is also possible to specify "default".

If `value` has length greater than 1 it is assumed to contain a description of the colors which are to make up the new palette. The maximum size for a palette is 1024 entries.

If `value` is omitted, no change is made to the current palette.

There is only one palette setting for all devices in an R session. If the palette is changed, the new palette applies to all subsequent plotting.

The current palette also applies to re-plotting (for example if an on-screen device is resized or `dev.copy` or `replayPlot` is used). The palette is recorded on the display list at the start of each page and when it is changed.

Value

`palette()` returns a character vector giving the colors from the palette which *was* in effect. This is `invisible` unless the argument is omitted.

`palette.pals()` returns a character vector giving the names of predefined palettes.

`palette.colors()` returns a vector of R colors. By default (if `names = FALSE` the vector has no names. If `names = TRUE`, the function attempts to return a named vector if possible, i.e., for those palettes that provide names for their colors (e.g., "Okabe-Ito", "Tableau 10", or "Alphabet").

See Also

`colors` for the vector of built-in named colors; `hsv`, `gray`, `hcl.colors`, ... to construct colors. `adjustcolor`, e.g., for tweaking existing palettes; `colorRamp` to interpolate colors, making custom palettes; `col2rgb` for translating colors to RGB 3-vectors.

Examples

```

require(graphics)

palette() # obtain the current palette
palette("R3");palette() # old default palette
palette("ggplot2") # ggplot2-style palette
palette()

palette(hcl.colors(8, "viridis"))

(palette(gray(seq(0,.9,length.out = 25)))) # gray scales; print old palette
matplot(outer(1:100, 1:30), type = "l", lty = 1,lwd = 2, col = 1:30,
        main = "Gray Scales Palette",
        sub = "palette(gray(seq(0, .9, len=25)))")
palette("default") # reset back to the default

## on a device where alpha transparency is supported,
## use 'alpha = 0.3' transparency with the default palette :
mycols <- adjustcolor(palette(), alpha.f = 0.3)
opal <- palette(mycols)
x <- rnorm(1000); xy <- cbind(x, 3*x + rnorm(1000))
plot (xy, lwd = 2,
      main = "Alpha-Transparency Palette\n alpha = 0.3")
xy[,1] <- -xy[,1]
points(xy, col = 8, pch = 16, cex = 1.5)
palette("default")

## List available built-in palettes
palette.pals()

## Demonstrate the colors 1:8 in different palettes using a custom matplot()

{
  cols <- sapply(palette, palette.colors, n = n, recycle = TRUE)
  ncol <- ncol(cols)
  nswatch <- min(ncol, nrow)
  op <- par(mar = rep(0.1, 4),

```

```

        mfrow = c(1, min(5, ceiling(ncol/nrow))),
        cex = cex, ...)
    on.exit(par(op))
    while (length(palette)) {
      subset <- seq_len(min(nrow, ncol(cols)))
      plot.new()
      plot.window(c(0, n), c(0.25, nrow + 0.25))
      y <- rev(subset)
      text(0, y + 0.1, palette[subset], adj = c(0, 0))
      y <- rep(y, each = n)
      rect(rep(0:(n-1), n), y, rep(1:n, n), y - 0.5,
            col = cols[, subset], border = border)
      palette <- palette[-subset]
      cols <- cols[, -subset, drop = FALSE]
    }

palette.swatch()

palette.swatch(n = 26) # show full "Alphabet"; recycle most others

```

Palettes

Color Palettes

Description

Create a vector of n contiguous colors.

Usage

```

hcl.colors(n, palette = "viridis", alpha = NULL, rev = FALSE, fixup = TRUE)
hcl.pals(type = NULL)

rainbow(n, s = 1, v = 1, start = 0, end = max(1, n - 1)/n,
        alpha, rev = FALSE)
heat.colors(n, alpha, rev = FALSE)
terrain.colors(n, alpha, rev = FALSE)
topo.colors(n, alpha, rev = FALSE)
cm.colors(n, alpha, rev = FALSE)

```

Arguments

<code>n</code>	the number of colors (≥ 1) to be in the palette.
<code>palette</code>	a valid palette name (one of <code>hcl.pals()</code>). The name is matched to the list of available palettes, ignoring upper vs. lower case, spaces, dashes, etc. in the matching.
<code>alpha</code>	an alpha-transparency level in the range [0,1] (0 means transparent and 1 means opaque), see argument <code>alpha</code> in <code>hsv</code> and <code>hcl</code> , respectively. A <i>missing</i> , i.e., not explicitly specified <code>alpha</code> is equivalent to <code>alpha = NULL</code> , which does <i>not</i> add opacity codes ("FF") to the individual color hex codes.
<code>rev</code>	logical indicating whether the ordering of the colors should be reversed.

<code>fixup</code>	logical indicating whether the resulting color should be corrected to RGB coordinates in [0,1], see hcl .
<code>type</code>	the type of palettes to list: "qualitative", "sequential", "diverging", or "divergingx". NULL lists all palettes.
<code>s, v</code>	the 'saturation' and 'value' to be used to complete the HSV color descriptions.
<code>start</code>	the (corrected) hue in [0,1] at which the rainbow begins.
<code>end</code>	the (corrected) hue in [0,1] at which the rainbow ends.

Details

All of these functions (except the helper function `hcl.pals`) create a vector of `n` contiguous colors, either based on the HSV color space (rainbow, heat, terrain, topography, and cyan-magenta colors) or the perceptually-based HCL color space.

HSV (hue-saturation-value) is a simple transformation of the RGB (red-green-blue) space which was therefore a convenient choice for color palettes in many software systems (see also [hsv](#)). However, HSV colors capture the perceptual properties hue, colorfulness/saturation/chroma, and lightness/brightness/luminance/value only poorly and consequently the corresponding palettes are typically not a good choice for statistical graphics and data visualization.

In contrast, HCL (hue-chroma-luminance) colors are much more suitable for capturing human color perception (see also [hcl](#)) and better color palettes can be derived based on HCL coordinates. Conceptually, three types of palettes are often distinguished:

- **Qualitative:** For coding categorical information, i.e., where no particular ordering of categories is available and every color should receive the same perceptual weight.
- **Sequential:** For coding ordered/numeric information, i.e., where colors go from high to low (or vice versa).
- **Diverging:** Designed for coding numeric information around a central neutral value, i.e., where colors diverge from neutral to two extremes.

The `hcl.colors` function provides a basic and lean implementation of the pre-specified palettes in the **colorspace** package. In addition to the types above, the functions distinguish “diverging” palettes where the two arms are restricted to be rather balanced as opposed to flexible “divergingx” palettes that combine two sequential palettes without any restrictions. The latter group also includes the *cividis* palette as it is based on two different hues (blue and yellow) but it is actually a sequential palette (going from dark to light).

The names of all available HCL palettes can be queried with the `hcl.pals` function and they are also visualized by color swatches in the examples. Many of the palettes closely approximate palettes of the same name from various other packages (including **RColorBrewer**, **rcartocolor**, **viridis**, **scico**, among others).

The default HCL palette is the widely used *viridis* palette which is a sequential palette with relatively high chroma throughout so that it also works reasonably well as a qualitative palette. However, while *viridis* is a rather robust default palette, more suitable HCL palettes are available for most visualizations.

For example, "Dark 3" works well for shading points or lines in up to five groups, "YlGnBu" is a sequential palette similar to "viridis" but with aligned chroma/luminance, and "Green-Brown" or "Blue-Red 3" are colorblind-safe diverging palettes.

Further qualitative palettes are provided in the `palette.colors` function. While the qualitative palettes in `hcl.colors` are always based on the same combination of chroma and luminance, the `palette.colors` vary in chroma and luminance up to a certain degree. The advantage of fixing chroma/luminance is that the perceptual weight of the resulting colors is more balanced. The

advantage of allowing variation is that more distinguishable colors can be obtained, especially for viewers with color vision deficiencies.

Note that the `rainbow` function implements the (in-)famous rainbow (or jet) color palette that was used very frequently in many software packages but has been widely criticized for its many perceptual problems. It is specified by a `start` and `end` hue with red = 0, yellow = $\frac{1}{6}$, green = $\frac{2}{6}$, cyan = $\frac{3}{6}$, blue = $\frac{4}{6}$, and magenta = $\frac{5}{6}$. However, these are very flashy and unbalanced with respect to both chroma and luminance which can lead to various optical illusions. Also, the hues that are equispaced in RGB space tend to cluster at the red, green, and blue primaries. Therefore, it is recommended to use a suitable palette from `hcl.colors` instead of `rainbow`.

Value

A character vector `cv` containing either palette names (for `hcl.pals`) or `n` hex color codes (for all other functions). The latter can be used either to create a user-defined color palette for subsequent graphics by `palette(cv)`, a `col` = specification in graphics functions or in `par`.

```

Description

pdf starts the graphics device driver for producing PDF graphics.

Usage

```
pdf(file = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
    width, height, onefile, family, title, fonts, version,
    paper, encoding, bg, fg, pointsize, pagecentre, colormodel,
    useDingbats, useKerning, fillOddEven, compress,
    timestamp, producer, author)
```

Arguments

file	a character string giving the file path. See the section ‘File specifications’ for further details.
width,height	the width and height of the graphics region in inches. The default values are 7.
onefile	logical: if true (the default) allow multiple figures in one file. If false, generate a file with name containing the page number for each page. Defaults to TRUE, and forced to true if file is a pipe.
family	the initial font family to be used, normally as a character string. See the section ‘Families’. Defaults to "Helvetica".
title	title string to embed as the ‘/Title’ field in the document metadata. Defaults to "R Graphics Output"; use an empty string (" ") to omit the field.
fonts	a character vector specifying R graphics font family names for additional fonts which will be included in the PDF file. Defaults to NULL.
version	a string describing the PDF version that will be required to view the output. This is a minimum, and will be increased (with a warning) if necessary. Defaults to "1.4", but see ‘Details’.
paper	the target paper size. The choices are "a4", "letter", "legal" (or "us") and "executive" (and these can be capitalized), or "a4r" and "USr" for rotated (‘landscape’). The default is "special", which means that the width and height specify the paper size. A further choice is "default"; if this is selected, the paper size is taken from the option "papersize" if that is set and as "a4" if it is unset or empty. Defaults to "special".
encoding	the name of an encoding file. Defaults to "default". The latter is interpreted on Unix-alikes as "ISOLatin1.enc" unless the locale is recognized as corresponding to a language using ISO 8859- $\{2,5,7,13,15\}$ or KOI8- $\{R,U\}$. on Windows as "CP1250.enc" (Central European), "CP1251.enc" (Cyrillic), "CP1253.enc" (Greek) or "CP1257.enc" (Baltic) if one of those codepages is in use, otherwise "WinAnsi.enc" (codepage 1252). The file is looked for in the ‘enc’ directory of package grDevices if the path does not contain a path separator. An extension ".enc" can be omitted.
bg	the initial background color to be used. Defaults to "transparent".

<code>fg</code>	the initial foreground color to be used. Defaults to "black".
<code>pointsize</code>	the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.
<code>pagecentre</code>	logical: should the device region be centred on the page? – is only relevant for paper != "special". Defaults to TRUE.
<code>colormodel</code>	a character string describing the color model: currently allowed values are "srgb", "gray" (or "grey") and "cmyk". Defaults to "srgb". See section 'Color models'.
<code>useDingbats</code>	logical. Should small circles be rendered <i>via</i> the Dingbats font? Defaults to FALSE. If TRUE, this can produce smaller and better output, but can cause font display problems in broken PDF viewers: although this font is one of the 14 guaranteed to be available in all PDF viewers, that guarantee is not always honoured. For Unix-alikes (including macOS) see the 'Note' for a possible fix for some viewers.
<code>useKerning</code>	logical. Should kerning corrections be included in setting text and calculating string widths? Defaults to TRUE.
<code>fillOddEven</code>	logical controlling the polygon fill mode: see polygon for details. Defaults to FALSE.
<code>compress</code>	logical. Should PDF streams be generated with Flate compression? Defaults to TRUE.
<code>timestamp</code>	logical. If FALSE, omit the '/CreationDate' and '/ModDate' metadata fields. Defaults to TRUE.
<code>producer</code>	logical. If FALSE, omit the '/Producer' metadata field. Defaults to TRUE.
<code>author</code>	author string to embed as the '/Author' field in the document metadata. Defaults to "", omitting the field.

Details

All arguments except `file` default to values given by `pdf.options()`. The ultimate defaults are quoted in the arguments section.

`pdf()` opens the file `file` and the PDF commands needed to plot any graphics requested are sent to that file.

The `family` argument can be used to specify a PDF-specific font family as the initial/default font for the device. If additional font families are to be used they should be included in the `fonts` argument.

If a device-independent R graphics font family is specified (e.g., via `par(family = )` in the graphics package), the PDF device makes use of the PostScript font mappings to convert the R graphics font family to a PDF-specific font family description. (See the documentation for [pdfFonts](#).)

This device does *not* embed fonts in the PDF file, so it is only straightforward to use mappings to the font families that can be assumed to be available in any PDF viewer: "Times" (equivalently "serif"), "Helvetica" (equivalently "sans") and "Courier" (equivalently "mono"). Other families may be specified, but it is the user's responsibility to ensure that these fonts are available on the system and third-party software (e.g., Ghostscript) may be required to embed the fonts so that the PDF can be included in other documents (e.g., LaTeX): see [embedFonts](#). The URW-based families described for in section 'Families' can be used with viewers, platform dependently:

on Unix-alikes viewers set up to use URW fonts, which is usual with those based on xpdf or Ghostscript.

on Windows viewers such as GSView which utilise URW fonts.

Since `embedFonts` makes use of Ghostscript, it should be able to embed the URW-based families for use with other viewers.

The PDF produced is fairly simple, with each page being represented as a single stream (by default compressed and possibly with references to raster images). The R graphics model does not distinguish graphics objects at the level of the driver interface.

The `version` argument declares the version of PDF that gets produced. The version must be at least 1.2 when compression is used, 1.4 for semi-transparent output to be understood, and at least 1.3 if CID fonts are to be used: if any of these features are used the version number will be increased (with a warning). (PDF 1.4 was first supported by Acrobat 5 in 2001; it is very unlikely not to be supported in a current viewer.)

Line widths as controlled by `par(lwd = )` are in multiples of 1/96 inch. Multiples less than 1 are allowed. `pch = "."` with `cex = 1` corresponds to a square of side 1/72 inch, which is also the 'pixel' size assumed for graphics parameters such as `"cra"`.

The `paper` argument sets the `'MediaBox'` entry in the file, which defaults to `width` by `height`. If it is set to something other than `"special"`, a device region of the specified size is (by default) centred on the rectangle given by the paper size: if either `width` or `height` is less than 0.1 or too large to give a total margin of 0.5 inch, it is reset to the corresponding paper dimension minus 0.5. Thus if you want the default behaviour of `postscript` use `pdf(paper = "a4r", width = 0, height = 0)` to centre the device region on a landscape A4 page with 0.25 inch margins.

When the background colour is fully transparent (as is the initial default value), the PDF produced does not paint the background. Most PDF viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

File specifications

Tilde expansion (see `path.expand`) is done on the `file` argument. An input with a marked encoding is converted to the native encoding or an error is given.

For use with `onefile = FALSE`, give a C integer format such as `"Rplot%03d.pdf"` (the default in that case) which is expanded using the page number, so this uses files `'Rplot001.pdf'`, ..., `'Rplot999.pdf'`, `'Rplot1000.pdf'`,

A single integer format matching the regular expression `"%[#0+==-]*[0-9.]*[diouxX]"` is allowed in `file`. The character string should not otherwise contain a `%`: if it is really necessary, use `%%` in the string for `%` in the file path.

For `pdf`, `file` can be `NULL` when no external file is created (effectively, no drawing occurs), but the device may still be queried (e.g., for the size of text by (base graphics) `strwidth` or (grid) `stringWidth`).

Families

Font families are collections of fonts covering the five font faces, (conventionally plain, bold, italic, bold-italic and symbol) selected by the graphics parameter `par(font = )` or the grid parameter `gpar(fontface = )`. Font families can be specified either as an initial/default font family for the device via the `family` argument or after the device is opened by the graphics parameter `par(family = )` or the grid parameter `gpar(fontfamily = )`. Families which will be used in addition to the initial family must be specified in the `fonts` argument when the device is opened.

Font families are declared via a call to `pdfFonts` or `postscriptFonts`.

The argument `family` specifies the initial/default font family to be used. In normal use it is one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times", and refers to the standard Adobe PostScript fonts families of those names which are included (or cloned) in all common PDF/PostScript renderers.

Many PDF/PostScript renderers (including those based on Ghostscript) use the URW equivalents of these fonts, which are "URWGothic", "URWBookman", "NimbusMon", "NimbusSan", "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" respectively. If your viewer is using URW fonts, you will obtain access to more characters and more appropriate metrics by using these names. To make these easier to remember, "URWHelvetica" == "NimbusSan" and "URWTimes" == "NimbusRom" are also supported. However, if the viewer is not using URW fonts (for example Adobe Acrobat Reader) it may substitute inappropriately or not render at all. (Consider using `embedFonts`.)

As from R 4.4.0 there is support for URW 2.0 fonts in families "URW2Helvetica" (with 'Oblique' fonts), "URW2HelveticaItalic" (with 'Italic' fonts), "URW2Times" and "NimbusMonoPS". As recent versions of Ghostscript will render with (and embed) these fonts, these families should be used instead of "URWHelvetica", "URWTimes", "NimbusSan", "NimbusRom", and "NimbusMon"

Another type of family makes use of CID-keyed fonts for East Asian languages – see `pdfFonts`.

The `family` argument is normally a character string naming a font family, but family objects generated by `Type1Font` and `CIDFont` are also accepted. For compatibility with earlier versions of R, the initial family can also be specified as a vector of four or five afm files.

Note that R does not embed the font(s) used in the PostScript output: see `embedFonts` for a utility to help do so.

Viewers and embedding applications frequently substitute fonts for those specified in the family, and the substitute will often have slightly different font metrics. `useKerning = TRUE` spaces the letters in the string using kerning corrections for the intended family: this may look uglier than `useKerning = FALSE`.

Encodings

Encodings describe which glyphs are used to display the character codes (in the range 0–255). Most commonly R uses ISO Latin 1 encoding, and the examples for `text` are in that encoding. However, the encoding used on machines running R may well be different, and by using the `encoding` argument the glyphs can be matched to encoding in use. This suffices for European and Cyrillic languages, but not for East Asian languages. For the latter, composite CID fonts are used. These fonts are useful for other languages: for example they may contain Greek glyphs. (The rest of this section applies only when CID fonts are not used.)

None of this will matter if only ASCII characters (codes 32–126) are used as all the encodings (except "TeXtext") agree over that range. Some encodings are supersets of ISO Latin 1. However, if accented and special characters do not come out as you expect, you may need to change the encoding. Some other encodings are supplied with R: "ISOLatin2.enc" (Central/Eastern Europe), "ISOLatin7.enc" (ISO 8859-13, 'Baltic Rim'), "ISOLatin9.enc" (ISO 8859-15, including Euro), "Cyrillic.enc" (ISO 8859-5), "KOI8-R.enc", "KOI8-U.enc", and the Windows encodings "WinAnsi.enc" (also known as "CP1252.enc", "CP1250.enc" (Central/Eastern Europe), "CP1251.enc" (Cyrillic), "Greek.enc" (ISO 8859-7), "CP1253.enc" (modern Greek) and "CP1257.enc" ('Baltic Rim')). Note that many glyphs in these encodings are not in the fonts corresponding to the standard families. (The Adobe ones for all but Courier, Helvetica and Times cover little more than Latin-1,

whereas the URW ones also cover Latin-2, Latin-7, Latin-9 and Cyrillic but no Greek. The Adobe exceptions cover the Latin character sets, but not the Euro.)

NB: support for encodings other than "ISOLatin1.enc" (and the Windows ones on Windows) depends on support by the platform's `libiconv` in a UTF-8 locale.

If you specify the encoding, it is your responsibility to ensure that the PostScript font contains the glyphs used. One issue here is the Euro symbol which is in several encodings (including WinAnsi and ISOLatin9 encodings) but may well not be in the PostScript fonts. (It is in the URW variants; it is not in the supplied Adobe Font Metric files so will not be centred correctly.)

There is an exception. Character 45 ("-") is always set as minus (its value in Adobe ISOLatin1) even though it is hyphen in the other encodings. Hyphen is available as character 173 (octal 0255) in all the Latin encodings, Cyrillic and Greek. (This can be entered as "\u00ad" in a UTF-8 locale.) There are some discrepancies in accounts of glyphs 39 and 96: the supplied encodings (except CP1250 and CP1251) treat these as 'quoteright' and 'quoteleft' (rather than 'quotesingle'/'acute' and 'grave' respectively), as they are in the Adobe documentation.

Color models

The default color model ("srgb") is sRGB. Model "gray" (or "grey") maps sRGB colors to greyscale using perceived luminosity (biased towards green). "cmyk" outputs in CMYK colorspace. The simplest possible conversion from sRGB to CMYK is used (https://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK), and raster images are output in RGB.

Also available for backwards compatibility is model "rgb" which uses uncalibrated RGB and corresponds to the model used with that name in R prior to 2.13.0. Some viewers may render some plots in that colorspace faster than in sRGB, and the plot files will be smaller.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
- Circles of any radius are allowed. If `useDingbats = TRUE`, opaque circles of less than 10 big points radius are rendered using char 108 in the Dingbats font: all semi-transparent and larger circles using a Bézier curve for each quadrant.
- Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

Printing

Except on Windows it is possible to print directly from pdf by something like (this is appropriate for a CUPS printing system):

```
pdf("|lp -o landscape", paper = "a4r")
```

This forces `onefile = TRUE`.

Note

If you have drawn any typeset glyphs (see [glyphInfo](#)) then it is *highly* recommended that you use [embedGlyphs](#) to embed the relevant fonts.

Note

If you see problems with PDF output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and macOS systems have these problems, and no obvious way to turn off graphics anti-aliasing.

Acrobat Reader does not use the fonts specified but rather emulates them from multiple-master fonts. This can be seen in imprecise centering of characters, for example the multiply and divide signs in Helvetica. This can be circumvented by embedding fonts where possible. Most other viewers substitute fonts, e.g. URW fonts for the standard Helvetica and Times fonts, and these too often have different font metrics from the true fonts.

Acrobat Reader can be extended by ‘font packs’, and these will be needed for the full use of encodings other than Latin-1 (although they may be offered for download as needed).

On some Unix-alike systems: If `useDingbats = TRUE`, the default plotting character `pch = 1` was displayed in some PDF viewers incorrectly as a "q" character. (These seem to be viewers based on the ‘poppler’ PDF rendering library). This may be due to incorrect or incomplete mapping of font names to those used by the system. Adding the following lines to ‘`~/.fonts.conf`’ or ‘`/etc/fonts/local.conf`’ may circumvent this problem, although this has largely been corrected on the affected systems.

```
<fontconfig>
<alias binding="same">
  <family>ZapfDingbats</family>
  <accept><family>Dingbats</family></accept>
</alias>
</fontconfig>
```

Some further workarounds for problems with symbol fonts on viewers using ‘fontconfig’ are given in the ‘Cairo Fonts’ section of the help for [X11](#).

On Windows: The TeXworks PDF viewer was one of those which has been seen to fail to display Dingbats (used by e.g. `pch = 1`) correctly. Whereas on other platforms the problems seen were incorrect output, on Windows points were silently omitted: however recent versions seem to manage to display Dingbats.

There was a different font bug in the `pdf.js` viewer included in Firefox: that mapped Dingbats to the Symbol font and so displayed symbols such `pch = 1` as lambda.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Murrell P, Ripley BD (2006). “Non-Standard Fonts in PostScript and PDF graphics.” *R News*, **6**(2), 41–47. <https://journal.r-project.org/articles/RN-2006-016/>.

Examples

```
## Test function for encodings
TestChars <- function(encoding = "ISOLatin1", ...)
{
  pdf(encoding = encoding, ...)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings.
TestChars("ISOLatin2")
## this does not view properly in older viewers.
TestChars("ISOLatin2", family = "URWHelvetica")
## works well for viewing in gs-based viewers, and often in xpdf.
```

pdf.options

Auxiliary Function to Set/View Defaults for Arguments of pdf

Description

The auxiliary function `pdf.options` can be used to set or view (if called without arguments) the default values for most of the arguments to [pdf](#).

`pdf.options` needs to be called before calling `pdf`, and the default values it sets can be overridden by supplying arguments to `pdf`.

Usage

```
pdf.options(..., reset = FALSE)
```

Arguments

<code>...</code>	arguments <code>width</code> , <code>height</code> , <code>onfile</code> , <code>family</code> , <code>title</code> , <code>fonts</code> , <code>version</code> , <code>paper</code> , <code>encoding</code> , <code>bg</code> , <code>fg</code> , <code>pointsize</code> , <code>pagecentre</code> , <code>colormodel</code> , <code>useDingbats</code> , <code>useKerning</code> , <code>fillOddEven</code> , <code>compress</code> , <code>timestamp</code> , <code>producer</code> and <code>author</code> can be supplied.
<code>reset</code>	logical: should the defaults be reset to their ‘factory-fresh’ values?

Details

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

Value

A named list of all the defaults. If any arguments are supplied the return values are the old values and the result has the visibility flag turned off.

Examples

```
pdf.options(bg = "pink")
utils::str(pdf.options())
pdf.options(reset = TRUE) # back to factory-fresh
```

pictex

A PicTeX Graphics Driver

Description

This function produces simple graphics suitable for inclusion in TeX and LaTeX documents. It dates from the very early days of R and is for historical interest only. It was deprecated in R 4.4.0. Consider the **tikzDevice** instead.

Usage

```
pictex(file = "Rplots.tex", width = 5, height = 4, debug = FALSE,
       bg = "white", fg = "black")
```

Arguments

file	the file path where output will appear. Tilde expansion (see path.expand) is done. An input with a marked encoding is converted to the native encoding or an error is given.
width	The width of the plot in inches.
height	the height of the plot in inches.
debug	should debugging information be printed.
bg	the background color for the plot. Ignored.
fg	the foreground color for the plot. Ignored.

Details

This driver is much more basic than the other graphics drivers included in R. It does not have any font metric information, so the use of [plotmath](#) is not supported.

Line widths are ignored except when setting the spacing of line textures. `pch = "."` corresponds to a square of side 1pt.

This device does not support colour (nor does the PicTeX package), and all colour settings are ignored.

Note that text is recorded in the file as-is, so annotations involving TeX special characters (such as ampersand and underscore) need to be quoted as they would be when entering TeX.

Multiple plots will be placed as separate environments in the output file.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*.

- The default device size is 5 inches by 4 inches.
- There is no `pointsize` argument: the default size is interpreted as 10 point.
- The only font family is `cmss10`.
- Line widths are only used when setting the spacing on line textures.
- Circle of any radius are allowed.
- Colour is not supported.

Author(s)

This driver was provided around 1996–7 by Valerio Aimale of the Department of Internal Medicine, University of Genoa, Italy.

plotmath

Mathematical Annotation in R

Description

If the `text` argument to one of the text-drawing functions (`text`, `mtext`, `axis`, `legend`) in R is an expression, the argument is interpreted as a mathematical expression and the output will be formatted according to TeX-like rules. Expressions can also be used for titles, subtitles and x- and y-axis labels (but not for axis labels on `persp` plots).

In most cases other language objects (names and calls, including formulas) are coerced to expressions and so can also be used.

Details

A mathematical expression must obey the normal rules of syntax for any R expression, but it is interpreted according to very different rules than for normal R expressions.

It is possible to produce many different mathematical symbols, generate sub- or superscripts, produce fractions, etc.

The output from `demo(plotmath)` includes several tables which show the available features. In these tables, the columns of grey text show sample R expressions, and the columns of black text show the resulting output.

The available features are also described in the tables below:

Syntax	Meaning
<code>x + y</code>	x plus y
<code>x - y</code>	x minus y
<code>x*y</code>	juxtapose x and y
<code>x/y</code>	x forwardslash y
<code>x %+-% y</code>	x plus or minus y
<code>x %/% y</code>	x divided by y
<code>x %*% y</code>	x times y
<code>x %.% y</code>	x $\cdot$ y
<code>x[i]</code>	x subscript i
<code>x^2</code>	x superscript 2
<code>paste(x, y, z)</code>	juxtapose x, y, and z
<code>sqrt(x)</code>	square root of x
<code>sqrt(x, y)</code>	y-th root of x
<code>x == y</code>	x equals y
<code>x != y</code>	x is not equal to y
<code>x < y</code>	x is less than y
<code>x <= y</code>	x is less than or equal to y
<code>x > y</code>	x is greater than y
<code>x >= y</code>	x is greater than or equal to y

<code>!x</code>	not x
<code>x %~~% y</code>	x is approximately equal to y
<code>x %~% y</code>	x and y are congruent
<code>x %==% y</code>	x is defined as y
<code>x %prop% y</code>	x is proportional to y
<code>x %~% y</code>	x is distributed as y
<code>plain(x)</code>	draw x in normal font
<code>bold(x)</code>	draw x in bold font
<code>italic(x)</code>	draw x in italic font
<code>bolditalic(x)</code>	draw x in bold italic font
<code>symbol(x)</code>	draw x in symbol font
<code>list(x, y, z)</code>	comma-separated list
<code>...</code>	ellipsis (height varies)
<code>cdots</code>	ellipsis (vertically centred)
<code>ldots</code>	ellipsis (at baseline)
<code>x %subset% y</code>	x is a proper subset of y
<code>x %subsepeq% y</code>	x is a subset of y
<code>x %notsubset% y</code>	x is not a subset of y
<code>x %supset% y</code>	x is a proper superset of y
<code>x %supsepeq% y</code>	x is a superset of y
<code>x %in% y</code>	x is an element of y
<code>x %notin% y</code>	x is not an element of y
<code>hat(x)</code>	x with a circumflex
<code>tilde(x)</code>	x with a tilde
<code>dot(x)</code>	x with a dot
<code>ring(x)</code>	x with a ring
<code>bar(xy)</code>	xy with bar
<code>widehat(xy)</code>	xy with a wide circumflex
<code>widetilde(xy)</code>	xy with a wide tilde
<code>x %<->% y</code>	x double-arrow y
<code>x %->% y</code>	x right-arrow y
<code>x %<-% y</code>	x left-arrow y
<code>x %up% y</code>	x up-arrow y
<code>x %down% y</code>	x down-arrow y
<code>x %<=>% y</code>	x is equivalent to y
<code>x %=>% y</code>	x implies y
<code>x %<=% y</code>	y implies x
<code>x %dblup% y</code>	x double-up-arrow y
<code>x %dbldown% y</code>	x double-down-arrow y
<code>alpha - omega</code>	Greek symbols
<code>Alpha - Omega</code>	uppercase Greek symbols
<code>theta1, phi1, sigma1, omega1</code>	cursive Greek symbols
<code>Upsilon1</code>	capital upsilon with hook
<code>aleph</code>	first letter of Hebrew alphabet
<code>infinity</code>	infinity symbol
<code>partialdiff</code>	partial differential symbol
<code>nabla</code>	nabla, gradient symbol
<code>32*degree</code>	32 degrees
<code>60*minute</code>	60 minutes of angle
<code>30*second</code>	30 seconds of angle
<code>displaystyle(x)</code>	draw x in normal size (extra spacing)
<code>textstyle(x)</code>	draw x in normal size

<code>scriptstyle(x)</code>	draw x in small size
<code>scriptscriptstyle(x)</code>	draw x in very small size
<code>underline(x)</code>	draw x underlined
<code>x ~ y</code>	put extra space between x and y
<code>x + phantom(0) + y</code>	leave gap for "0", but don't draw it
<code>x + over(1, phantom(0))</code>	leave vertical gap for "0" (don't draw)
<code>frac(x, y)</code>	x over y
<code>over(x, y)</code>	x over y
<code>atop(x, y)</code>	x over y (no horizontal bar)
<code>sum(x[i], i==1, n)</code>	sum x[i] for i equals 1 to n
<code>prod(plain(P)(X==x), x)</code>	product of P(X=x) for all values of x
<code>integral(f(x)*dx, a, b)</code>	definite integral of f(x) wrt x
<code>union(A[i], i==1, n)</code>	union of A[i] for i equals 1 to n
<code>intersect(A[i], i==1, n)</code>	intersection of A[i]
<code>lim(f(x), x %->% 0)</code>	limit of f(x) as x tends to 0
<code>min(g(x), x > 0)</code>	minimum of g(x) for x greater than 0
<code>inf(S)</code>	infimum of S
<code>sup(S)</code>	supremum of S
<code>x^y + z</code>	normal operator precedence
<code>x^(y + z)</code>	visible grouping of operands
<code>x^{y + z}</code>	invisible grouping of operands
<code>group("(", list(a, b), ")")</code>	specify left and right delimiters
<code>bgroup("(", atop(x, y), ")")</code>	use scalable delimiters
<code>group(lceil, x, rceil)</code>	special delimiters
<code>group(lfloor, x, rfloor)</code>	special delimiters
<code>group(langle, list(x, y), rangle)</code>	special delimiters

The supported ‘scalable delimiters’ are `|` `(` `[` `{` and their right-hand versions. `"."` is equivalent to `" "`: the corresponding delimiter will be omitted. Delimiter `||` is supported but has the same effect as `|`. The special delimiters `lceil`, `lfloor`, `langle` (and their right-hand versions) are not scalable.

Note that `paste` does not insert spaces when juxtaposing, unlike (by default) the R function of that name.

The symbol font uses Adobe Symbol encoding so, for example, a lower case mu can be obtained either by the special symbol `mu` or by `symbol("m")`. This provides access to symbols that have no special symbol name, for example, the universal, or forall, symbol is `symbol("\042")`. To see what symbols are available in this way use `TestChars(font=5)` as given in the examples for [points](#): some are only available on some devices.

Note to TeX users: TeX’s ‘`\Upsilon`’ is `Upsilon1`, TeX’s ‘`\varepsilon`’ is close to `epsilon`, and there is no equivalent of TeX’s ‘`\epsilon`’. TeX’s ‘`\varpi`’ is close to `omega1`. `vartheta`, `varphi` and `varsigma` are allowed as synonyms for `thetal`, `phi1` and `sigma1`. `sigma1` is also known as `sigma`, its Unicode name.

Control characters (e.g., ‘`\n`’) are not interpreted in character strings in plotmath, unlike normal plotting.

The fonts used are taken from the current font family, and so can be set by `par(family=)` in base graphics, and `gpar(fontfamily=)` in package **grid**.

Note that **bold**, *italic* and **bolditalic** do not apply to symbols, and hence not to the Greek *symbols* such as mu which are displayed in the symbol font. They also do not apply to numeric constants.

Other symbols

On many OSes and some graphics devices many other symbols are available as part of the standard text font, and all of the symbols in the Adobe Symbol encoding are in principle available *via* changing the font face or (see ‘Details’) plotmath: see the examples section of `points` for a function to display them. (‘In principle’ because some of the glyphs are missing from some implementations of the symbol font.) Unfortunately, `pdf` and `postscript` have support for little more than European (not Greek) and CJK characters and the Adobe Symbol encoding (and in a few fonts, also Cyrillic characters).

On Unix-alikes: In a UTF-8 locale any Unicode character can be entered, perhaps as a ‘\uxxxx’ or ‘\Uxxxxxxxx’ escape sequence, but the issue is whether the graphics device is able to display the character. The widest range of characters is likely to be available in the `X11` device using `cairo`: see its help page for how installing additional fonts can help. This can often be used to display Greek *letters* in bold or italic.

On macOS the `quartz` device and the default system fonts have quite large coverage.

In non-UTF-8 locales there is normally no support for symbols not in the languages for which the current encoding was intended.

On Windows: Any Unicode character can be entered into a text string *via* a ‘\uxxxx’ escape, or used by number in a call to `points`. The `windows` family of devices can display such characters if they are available in the font in use. This can often be used to display Greek *letters* in bold or italic.

A good way to both find out which characters are available in a font and to determine the Unicode number is to use the ‘Character Map’ accessory (usually on the ‘Start’ menu under ‘Accessories->System Tools’). You can also copy-and-paste characters from the ‘Character Map’ window to the Rgui console (but not to Rterm).

Examples

```
require(graphics)

x <- seq(-4, 4, length.out = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
        main = expression(paste(plain(sin) * phi, " and ",
                                plain(cos) * phi)),
        ylab = expression("sin" * phi, "cos" * phi), # only 1st is taken
        xlab = expression(paste("Phase Angle ", phi)),
        col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
     labels = expression(-pi, -pi/2, 0, pi/2, pi))
```

```
## How to combine "math" and numeric variables :
plot(1:10, type="n", xlab="", ylab="", main = "plot math & numbers")
theta <- 1.23 ; mtext(bquote(hat(theta) == .(theta)), line = .25)
for(i in 2:9)
  text(i, i+1, substitute(list(xi, eta) == group("(", list(x,y), ")"),
    list(x = i, y = i+1)))
## note that both of these use calls rather than expressions.
##
text(1, 10, "Derivatives:", adj = 0)
text(1, 9.6, expression(
  "      first: {f * minute}(x) " == {f * minute}(x)), adj = 0)
text(1, 9.0, expression(
  "      second: {f * second}(x) " == {f * second}(x)), adj = 0)

## note the "{ .. }" trick to get "chained" equations:
plot(1:10, 1:10, main = quote(1 <= {1 < 2}))
text(4, 9, expression(hat(beta) == (X^t * X)^{-1} * X^t * y))
text(4, 8.4, "expression(hat(beta) == (X^t * X)^{-1} * X^t * y)",
  cex = .8)
text(4, 7, expression(bar(x) == sum(frac(x[i], n), i==1, n)))
text(4, 6.4, "expression(bar(x) == sum(frac(x[i], n), i==1, n))",
  cex = .8)
text(8, 5, expression(paste(frac(1, sigma*sqrt(2*pi)), " ",
  plain(e)^{frac(-(x-mu)^2, 2*sigma^2)})),
  cex = 1.2)

## some other useful symbols
plot.new(); plot.window(c(0,4), c(15,1))
text(1, 1, "universal", adj = 0); text(2.5, 1, "\\042")
text(3, 1, expression(symbol("\\042")))
text(1, 2, "existential", adj = 0); text(2.5, 2, "\\044")
text(3, 2, expression(symbol("\\044")))
text(1, 3, "suchthat", adj = 0); text(2.5, 3, "\\047")
text(3, 3, expression(symbol("\\047")))
text(1, 4, "therefore", adj = 0); text(2.5, 4, "\\134")
text(3, 4, expression(symbol("\\134")))
text(1, 5, "perpendicular", adj = 0); text(2.5, 5, "\\136")
text(3, 5, expression(symbol("\\136")))
text(1, 6, "circlemultiply", adj = 0); text(2.5, 6, "\\304")
text(3, 6, expression(symbol("\\304")))
text(1, 7, "circleplus", adj = 0); text(2.5, 7, "\\305")
text(3, 7, expression(symbol("\\305")))
text(1, 8, "emptyset", adj = 0); text(2.5, 8, "\\306")
text(3, 8, expression(symbol("\\306")))
text(1, 9, "angle", adj = 0); text(2.5, 9, "\\320")
text(3, 9, expression(symbol("\\320")))
text(1, 10, "leftangle", adj = 0); text(2.5, 10, "\\341")
text(3, 10, expression(symbol("\\341")))
text(1, 11, "rightangle", adj = 0); text(2.5, 11, "\\361")
text(3, 11, expression(symbol("\\361")))
```

Description

Graphics devices for BMP, JPEG, PNG and TIFF format bitmap files.

Usage

```

bmp(filename = "Rplot%03d.bmp",
     width = 480, height = 480, units = "px", pointsize = 12,
     bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

jpeg(filename = "Rplot%03d.jpeg",
     width = 480, height = 480, units = "px", pointsize = 12,
     quality = 75,
     bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

png(filename = "Rplot%03d.png",
     width = 480, height = 480, units = "px", pointsize = 12,
     bg = "white", res = NA, ...,
     type = c("cairo", "cairo-png", "Xlib", "quartz"), antialias)

tiff(filename = "Rplot%03d.tiff",
     width = 480, height = 480, units = "px", pointsize = 12,
     compression = c("none", "rle", "lzw", "jpeg", "zip",
                     "lzw+p", "zip+p",
                     "lerc", "lzma", "zstd", "webp"),
     bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

```

Arguments

filename	the output file path. The page number is substituted if a C integer format is included in the character string, as in the default. (Depending on the platform, the result should be less than <code>PATH_MAX</code> characters long, and may be truncated if not. See pdf for further details.) Tilde expansion is performed where supported by the platform. An input with a marked encoding is converted to the native encoding on an error is given.
width	the width of the device.
height	the height of the device.
units	The units in which height and width are given. Can be <code>px</code> (pixels, the default), <code>in</code> (inches), <code>cm</code> or <code>mm</code> .
pointsize	the default pointsize of plotted text, interpreted as big points (1/72 inch) at <code>res</code> ppi.
bg	the initial background colour: can be overridden by setting <code>par("bg")</code> .
quality	the ‘quality’ of the JPEG image, as a percentage. Smaller values will give more compression but also more degradation of the image.
compression	the type of compression to be used. Can also be a numeric value supported by the underlying <code>libtiff</code> library: see its ‘ <code>tiff.h</code> ’ header file. Ignored with a warning for <code>type = "quartz"</code> .

<code>res</code>	The nominal resolution in ppi which will be recorded in the bitmap file, if a positive integer. Also used for <code>units</code> other than the default, and to convert points to pixels.
<code>...</code>	for <code>type = "Xlib"</code> only, additional arguments to the underlying X11 device such as <code>fonts</code> or <code>family</code> . For types <code>"cairo"</code> and <code>"quartz"</code> , the <code>family</code> argument can be supplied. See the ‘Cairo fonts’ section in the help for X11 . For type <code>"cairo"</code> , the <code>symbolfamily</code> argument can be supplied. See X11.options .
<code>type</code>	character string, one of <code>"Xlib"</code> or <code>"quartz"</code> (some macOS builds) or <code>"cairo"</code> . The latter will only be available if the system was compiled with support for cairo – otherwise <code>"Xlib"</code> will be used. The default is set by <code>getOption("bitmapType")</code> – the ‘out of the box’ default is <code>"quartz"</code> or <code>"cairo"</code> where available, otherwise <code>"Xlib"</code> .
<code>antialias</code>	for <code>type = "cairo"</code> , giving the type of anti-aliasing (if any) to be used for fonts and lines (but not fills). See X11 . The default is set by X11.options . Also for <code>type = "quartz"</code> , where antialiasing is used unless <code>antialias = "none"</code> .

Details

Plots in PNG and JPEG format can easily be converted to many other bitmap formats, and both can be displayed in modern web browsers. The PNG format is lossless and is best for line diagrams and blocks of colour. The JPEG format is lossy, but may be useful for image plots, for example. BMP is a standard format on Windows. TIFF is a meta-format: the default format written by `tiff` is lossless and stores RGB (and alpha where appropriate) values uncompressed—such files are widely accepted, which is their main virtue over PNG.

The JPEG format only supports opaque backgrounds.

`png` supports transparent backgrounds: use `bg = "transparent"`. (Not all PNG viewers render files with transparency correctly.) When transparency is in use in the `type = "Xlib"` variant a very light grey is used as the background and so appears as transparent if used in the plot. This allows opaque white to be used, as in the example. The `type = "cairo"`, `type = "cairo-png"` and `type = "quartz"` variants allow semi-transparent colours, including on a transparent or semi-transparent background.

`tiff` with types `"cairo"` and `"quartz"` supports semi-transparent colours, including on a transparent or semi-transparent background. Compression type `"zip"` is ‘deflate (Adobe-style)’. Compression types `"lzw+p"` and `"zip+p"` use horizontal differencing (‘differencing predictor’, section 14 of the TIFF specification) in combination with the compression method, which is effective for continuous-tone images, especially colour ones.

The `jpeg` quality when used for `tiff` compression is fixed at 75.

R can be compiled without support for some or all of the types for each of these devices: this will be reported if you attempt to use them on a system where they are not supported. For `type = "Xlib"` they may not be usable unless the X11 display is available to the owner of the **R** process. `type = "cairo"` requires cairo 1.2 or later. `type = "quartz"` uses the [quartz](#) device and so is only available where that is (on some macOS builds: see [capabilities\("aqua"\)](#)).

By default no resolution is recorded in the file, except for BMP. Viewers will often assume a nominal resolution of 72 ppi when none is recorded. As resolutions in PNG files are recorded in pixels/metre, the reported ppi value will be changed slightly.

For graphics parameters that make use of dimensions in inches (including font sizes in points) the resolution used is `res` (or 72 ppi if unset).

png will normally use a palette if there are less than 256 colours on the page, and record a 24-bit RGB file otherwise (or a 32-bit ARGB file if `type = "cairo"` and non-opaque colours are used). However, `type = "cairo-png"` uses cairographics' PNG backend which will never use a palette and normally creates a larger 32-bit ARGB file—this may work better for specialist uses with semi-transparent colours.

Quartz-produced PNG and TIFF plots with a transparent background are recorded with a dark grey matte which will show up in some viewers, including Preview on macOS.

Unknown resolutions in BMP files are recorded as 72 ppi.

Value

A plot device is opened: nothing is returned to the R interpreter.

Warnings

Note that by default the `width` and `height` values are in pixels not inches. A warning will be issued if both are less than 20.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in `file`, the file will contain the last page plotted.

Differences between OSes

These functions are interfaces to three or more different underlying devices.

- On Windows, devices based on plotting to a hidden screen using Windows' GDI calls.
- On platforms with support for X11, plotting to a hidden X11 display.
- On macOS when working at the console and when R is compiled with suitable support, using Apple's Quartz plotting system.
- Where support has been compiled in for cairographics, plotting on cairo surfaces. This may use the native platform support for fonts, or it may use `fontconfig` to support a wide range of font formats.

Inevitably there will be differences between the options supported and output produced. Perhaps the most important are support for antialiased fonts and semi-transparent colours: the best results are likely to be obtained with the cairo- or Quartz-based devices where available.

The default extensions are `' .jpg'` and `' .tif'` on Windows, and `' .jpeg'` and `' .tiff'` elsewhere.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*.

- The default device size is in pixels.
- Font sizes are in big points interpreted at `res ppi`.
- The default font family is Helvetica.
- Line widths in 1/96 inch (interpreted at `res ppi`), minimum one pixel for `type = "Xlib"`, 0.01 for `type = "cairo"`.
- For `type = "Xlib"` circle radii are in pixels with minimum one.
- Colours are interpreted by the viewing application.

For `type = "quartz"` see the help for [quartz](#).

Note

For `type = "Xlib"` these devices are based on the [X11](#) device. The colour model used will be that set up by `X11.options` at the time the first Xlib-based device was opened (or the first after all such devices have been closed).

Support for compression types depends on the underlying 'libtiff' library: types "lerc", "lzma", "zstd" and "webp" are relatively recent additions and may well not be supported. They are also liable to be unsupported in TIFF viewers.

[Devices](#), `dev.print`

`capabilities` to see if these devices are supported by this build of R, and if `type = "cairo"` is supported.

`bitmap` provides an alternative way to generate plots in many bitmap formats that does not depend on accessing the X11 display but does depend on having GhostScript installed.

Ways to write raster images to bitmap formats are available in packages [jpeg](#), [png](#) and [tiff](#).

Examples

```
## these examples will work only if the devices are available
## and cairo or an X11 display or a macOS display is available.

## copy current plot to a (large) PNG file
## Not run: dev.print(png, filename = "myplot.png", width = 1024, height = 768)

png("myplot.png", bg = "transparent")
plot(1:10)
rect(1, 5, 3, 7, col = "white")
dev.off()

## will make myplot1.jpeg and myplot2.jpeg
jpeg("myplot%d.jpeg")
example(rect)
dev.off()
```

postscript	<i>PostScript Graphics</i>
------------	----------------------------

Description

postscript starts the graphics device driver for producing PostScript graphics.

Usage

```
postscript(file = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
  onefile, family, title, fonts, encoding, bg, fg,
  width, height, horizontal, pointsize,
  paper, pagecentre, print.it, command,
  colormodel, useKerning, fillOddEven)
```

Arguments

file	a character string giving the file path. If it is "", the output is piped to the command given by the argument <code>command</code>. If it is of the form "<code> cmd</code>", the output is piped to the command given by <code>cmd</code>. For use with <code>onefile = FALSE</code>, give a C integer format such as "<code>Rplot%03d.ps</code>" (the default in that case). The string should not otherwise contain a %: if it is really necessary, use %% in the string for % in the file name. A single integer format matching the regular expression "<code>%[#0+--]*[0-9.]*[diouxX]</code>" is allowed. Tilde expansion (see path.expand) is done. An input with a marked encoding is converted to the native encoding or an error is given. See also section ‘File specifications’ in the help for pdf for further details.
onefile	logical: if true (the default) allow multiple figures in one file. If false, generate a file name containing the page number for each page and use an EPSF header and no DocumentMedia comment. Defaults to TRUE.
family	the initial font family to be used, see the section ‘Families’ in pdf. Defaults to "Helvetica".
title	title string to embed as the Title comment in the file. Defaults to "R Graphics Output".
fonts	a character vector specifying additional R graphics font family names for font families whose declarations will be included in the PostScript file and are available for use with the device. See ‘Families’ below. Defaults to NULL.
encoding	the name of an encoding file. See pdf for details. Defaults to "default".
bg	the initial background color to be used. If "transparent" (or any other non-opaque colour), no background is painted. Defaults to "transparent".
fg	the initial foreground color to be used. Defaults to "black".
width, height	the width and height of the graphics region in inches. Default to 0. If <code>paper != "special"</code> and <code>width</code> or <code>height</code> is less than 0.1 or too large to give a total margin of 0.5 inch, the graphics region is reset to the corresponding paper dimension minus 0.5.
horizontal	the orientation of the printed image, a logical. Defaults to true, that is landscape orientation on paper sizes with width less than height.

<code>pointsize</code>	the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.
<code>paper</code>	the size of paper in the printer. The choices are "a4", "letter" (or "us"), "legal" and "executive" (and these can be capitalized). Also, "special" can be used, when arguments <code>width</code> and <code>height</code> specify the paper size. A further choice is "default" (the default): If this is selected, the paper size is taken from the option <code>"papersize"</code> if that is set and to "a4" if it is unset or empty.
<code>pagecentre</code>	logical: should the device region be centred on the page? Defaults to true.
<code>print.it</code>	logical: should the file be printed when the device is closed? (This only applies if <code>file</code> is a real file name.) Defaults to false.
<code>command</code>	the command to be used for 'printing'. Defaults to "default", the value of option <code>"printcmd"</code> . The length limit is <code>2*PATH_MAX</code> , typically 8096 bytes on Unix-alikes and 520 bytes on Windows. Recent Windows systems may be configured to use long paths, raising this limit currently to 10000.
<code>colormodel</code>	a character string describing the color model: currently allowed values as "srgb", "srgb+gray", "rgb", "rgb-nogray", "gray" (or "grey") and "cmyk". Defaults to "srgb". See section 'Color models'.
<code>useKerning</code>	logical. Should kerning corrections be included in setting text and calculating string widths? Defaults to TRUE.
<code>fillOddEven</code>	logical controlling the polygon fill mode: see polygon for details. Default FALSE.

Details

All arguments except `file` default to values given by `ps.options()`. The ultimate defaults are quoted in the arguments section.

`postscript` opens the file `file` and the PostScript commands needed to plot any graphics requested are written to that file. This file can then be printed on a suitable device to obtain hard copy.

The `file` argument is interpreted as a C integer format as used by `sprintf`, with integer argument the page number. The default gives files 'Rplot001.ps', ..., 'Rplot999.ps', 'Rplot1000.ps',

The postscript produced for a single R plot is EPS (*Encapsulated PostScript*) compatible, and can be included into other documents, e.g., into LaTeX, using `\includegraphics{<filename>}`. For use in this way you will probably want to use `setEPS()` to set the defaults as `horizontal = FALSE`, `onefile = FALSE`, `paper = "special"`. Note that the bounding box is for the *device* region: if you find the white space around the plot region excessive, reduce the margins of the figure region via `par(mar = )`.

Most of the PostScript prologue used is taken from the R character vector `.ps.prolog`. This is marked in the output, and can be changed by changing that vector. (This is only advisable for PostScript experts: the standard version is in `namespace:grDevices`.)

A PostScript device has a default family, which can be set by the user via `family`. If other font families are to be used when drawing to the PostScript device, these must be declared when the device is created via `fonts`; the font family names for this argument are R graphics font family names (see the documentation for `postscriptFonts`).

Line widths as controlled by `par(lwd = )` are in multiples of 1/96 inch: multiples less than 1 are allowed. `pch = "."` with `cex = 1` corresponds to a square of side 1/72 inch, which is also the 'pixel' size assumed for graphics parameters such as `"cra"`.

When the background colour is fully transparent (as is the initial default value), the PostScript produced does not paint the background. Almost all PostScript viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

TeX fonts

TeX has traditionally made use of fonts such as Computer Modern which are encoded rather differently, in a 7-bit encoding. This encoding can be specified by `encoding = "TeXtext.enc"`, taking care that the ASCII characters `< > \ _ { }` are not available in those fonts.

There are supplied families `"ComputerModern"` and `"ComputerModernItalic"` which use this encoding, and which are only supported for `postscript` (and not `pdf`). They are intended to use with the Type 1 versions of the TeX CM fonts. It will normally be possible to include such output in TeX or LaTeX provided it is processed with `dvips -Ppfb -j0` or the equivalent on your system. (`-j0` turns off font subsetting.) When `family = "ComputerModern"` is used, the italic/bold-italic fonts used are slanted fonts (`cmsl10` and `cmbxsl10`). To use text italic fonts instead, set `family = "ComputerModernItalic"`.

These families use the TeX math italic and symbol fonts for a comprehensive but incomplete coverage of the glyphs covered by the Adobe symbol font in other families. This is achieved by special-casing the postscript code generated from the supplied `'CM_symbol_10.afm'`.

Color models

The default color model (`"srgb"`) is sRGB.

The alternative `"srgb+gray"` uses sRGB for colors, but with pure gray colors (including black and white) expressed as greyscales (which results in smaller files and can be advantageous with some printer drivers). Conversely, its files can be rendered much slower on some viewers, and there can be a noticeable discontinuity in color gradients involving gray or white.

Other possibilities are `"gray"` (or `"grey"`) which used only greyscales (and converts other colours to a luminance), and `"cmyk"`. The simplest possible conversion from sRGB to CMYK is used (https://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK), and raster images are output in RGB.

Color models provided for backwards compatibility are `"rgb"` (which is RGB+gray) and `"rgb-nogray"` which use uncalibrated RGB (as used in R prior to 2.13.0). These result in slightly smaller files which may render faster, but do rely on the viewer being properly calibrated.

Printing

A postscript plot can be printed via `postscript` in two ways.

1. Setting `print.it = TRUE` causes the command given in argument `command` to be called with argument `"file"` when the device is closed. Note that the plot file is not deleted unless `command` arranges to delete it.
2. `file = ""` or `file = "|cmd"` can be used to print using a pipe. Failure to open the command will probably be reported to the terminal but not to R, in which case close the device by `dev.off` immediately.

On Windows the default `"printcmd"` is empty and will give an error if `print.it = TRUE` is used. Suitable commands to spool a PostScript file to a printer can be found in 'RedMon' suite available from <http://pages.cs.wisc.edu/~ghost/index.html>. The command will be run in a minimized window. GSView 4.x provides `'gsprint.exe'` which may be more convenient (it requires Ghostscript version 6.50 or later).

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
- Circle of any radius are allowed.
- Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

Raster images are currently limited to opaque colours.

Note

If you see problems with postscript output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and macOS systems have these problems, and no obvious way to turn off graphics anti-aliasing.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D’Urso <durso@hussle.harvard.edu>.

`cairo_ps` for another device that can produce PostScript.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Murrell P, Ripley BD (2006). “Non-Standard Fonts in PostScript and PDF graphics.” *R News*, 6(2), 41–47. <https://journal.r-project.org/articles/RN-2006-016/>.

Examples

```
require(graphics)
## Not run:
# open the file "foo.ps" for graphics output
postscript("foo.ps")
# produce the desired graph(s)
dev.off()           # turn off the postscript device
```

```

## On Unix-alikes only:
postscript("|lp -dlw")
# produce the desired graph(s)
dev.off()          # plot will appear on printer

## On Windows:
options(printcmd = 'redpr -P"\\printhost\\lw"')
postscript(file = tempfile("Rps."), print.it = TRUE)
# produce the desired graph(s)
dev.off()          # send plot file to the printer
## alternative using GSView 4.x :
options(printcmd = '/GhostGum/gsview/gsprint -query')

# for URW PostScript devices
postscript("foo.ps", family = "NimbusSan")

## for inclusion in Computer Modern TeX documents, perhaps
postscript("cm_test.eps", width = 4.0, height = 3.0,
          horizontal = FALSE, onefile = FALSE, paper = "special",
          family = "ComputerModern", encoding = "TeXtext.enc")
## The resultant postscript file can be used by dvips -Ppfb -j0.

## To test out encodings, you can use
TestChars <- function(encoding = "ISOLatin1", family = "URWHelvetica")
{
  postscript(encoding = encoding, family = family)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings. We use URW to get a complete enough
## set of font metrics.
TestChars()
TestChars("ISOLatin2")
TestChars("WinAnsi")

## End(Not run)

```

Description

These functions handle the translation of a R graphics font family name to a PostScript or PDF font description, used by the `postscript` or `pdf` graphics devices.

Usage

```
postscriptFonts(...)
pdfFonts(...)
```

Arguments

... either character strings naming mappings to display, or named arguments specifying mappings to add or change.

Details

If these functions are called with no argument they list all the existing mappings, whereas if they are called with named arguments they add (or change) mappings.

A PostScript or PDF device is created with a default font family (see the documentation for [postscript](#)), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in [par](#) and for "fontfamily" in [gpar](#) in the [grid](#) package).

The font family sent to the device is a simple string name, which must be mapped to a set of PostScript fonts. Separate lists of mappings for `postscript` and `pdf` devices are maintained for the current R session and can be added to by the user.

The `postscriptFonts` and `pdfFonts` functions can be used to list existing mappings and to define new mappings. The [Type1Font](#) and [CIDFont](#) functions can be used to create new mappings, when the `xxxFonts` function is used to add them to the database. See the examples.

Default mappings are provided for three device-independent family names: "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

Mappings for a number of standard Adobe fonts (and URW equivalents) are also provided: "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" and "Times"; "URWGothic", "URWBookman", "NimbusMon", "NimbusSan" (synonym "URWHelvetica"), "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" (synonym "URWTimes").

There are also mappings for "ComputerModern", "ComputerModernItalic" and "ArialMT" (Monotype Arial).

Finally, there are some default mappings for East Asian locales described in a separate section.

The specification of font metrics and encodings is described in the help for the [postscript](#) function.

The fonts are not embedded in the resulting PostScript or PDF file, so software including the PostScript or PDF plot file should either embed the font outlines (usually from '.pfb' or '.pfa' files) or use DSC comments to instruct the print spooler or including application to do so (see also [embedFonts](#)).

A font family has both an R-level name, the argument name used when `postscriptFonts` was called, and an internal name, the `family` component. These two names are the same for all the pre-defined font families.

Once a font family is in use it cannot be changed. 'In use' means that it has been specified *via* a `family` or `fonts` argument to an invocation of the same graphics device already in the R session.

Value

A list of one or more font mappings.

East Asian fonts

There are some default mappings for East Asian locales:

"Japan1", "Japan1HeiMin", "Japan1GothicBBB", and "Japan1Ryumin" for Japanese; "Korea1" and "Korea1deb" for Korean; "GB1" (Simplified Chinese) for mainland China and Singapore; "CNS1" (Traditional Chinese) for Hong Kong and Taiwan.

These refer to the following fonts

Japan1 (PS)	HeiseiKakuGo-W5 Linotype Japanese printer font
Japan1 (PDF)	KozMinPro-Regular-Acro from Adobe Reader 7.0 Japanese Font Pack
Japan1HeiMin (PS)	HeiseiMin-W3 Linotype Japanese printer font
Japan1HeiMin (PDF)	HeiseiMin-W3-Acro from Adobe Reader 7.0 Japanese Font Pack
Japan1GothicBBB	GothicBBB-Medium Japanese-market PostScript printer font
Japan1Ryumin	Ryumin-Light Japanese-market PostScript printer font
Korea1 (PS)	Baekmuk-Batang TrueType font found on some Linux systems
Korea1 (PDF)	HYSMyeongJoStd-Medium-Acro from Adobe Reader 7.0 Korean Font Pack
Korea1deb (PS)	Batang-Regular another name for Baekmuk-Batang
Korea1deb (PDF)	HYGothic-Medium-Acro from Adobe Reader 4.0 Korean Font Pack
GB1 (PS)	BousungEG-Light-GB TrueType font found on some Linux systems
GB1 (PDF)	STSong-Light-Acro from Adobe Reader 7.0 Simplified Chinese Font Pack
CNS1 (PS)	MOESung-Regular Ken Lunde's CJKV resources
CNS1 (PDF)	MSungStd-Light-Acro from Adobe Reader 7.0 Traditional Chinese Font Pack

BousungEG-Light-GB can be found at <https://ftp.gnu.org/pub/non-gnu/chinese-fonts-truetype/>. These will need to be installed or otherwise made available to the PostScript/PDF interpreter such as Ghostscript (and not all interpreters can handle TrueType fonts).

You may well find that your postscript/PDF interpreters has been set up to provide aliases for many of these fonts. For example, Ghostscript on Windows can optionally be installed to map common East Asian fonts names to Windows TrueType fonts. (You may want to add the -Acro versions as well.)

Adding a mapping for a CID-keyed font is for gurus only.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D'Urso.

`postscript` and `pdf`; `Type1Font` and `CIDFont` for specifying new font mappings.

Examples

```
postscriptFonts()
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
                     c("CM_regular_10.afm", "CM_boldx_10.afm",
                       "cmti10.afm", "cmbxti10.afm",
                       "CM_symbol_10.afm"),
                     encoding = "TeXtext.enc")
postscriptFonts(CMitalic = CMitalic)

## A CID font for Japanese using a different CMap and
## corresponding cmapEncoding.
`Jp_UCS-2` <- CIDFont("TestUCS2",
                     c("Adobe-Japan1-UniJIS-UCS2-H.afm",
                       "Adobe-Japan1-UniJIS-UCS2-H.afm",
                       "Adobe-Japan1-UniJIS-UCS2-H.afm",
                       "Adobe-Japan1-UniJIS-UCS2-H.afm"),
                     "UniJIS-UCS2-H", "UCS-2")
pdfFonts(`Jp_UCS-2` = `Jp_UCS-2`)
names(pdfFonts())
```

```
pretty.Date
```

Pretty Breakpoints for Date-Time Classes

Description

Compute a sequence of about $n+1$ equally spaced ‘nice’ values which cover the range of the values in x , possibly of length one, when $\min.n = 0$ and there is only one unique x .

Usage

```
## S3 method for class 'Date'
pretty(x, n = 5, min.n = n %/% 2, sep = " ", ...)
## S3 method for class 'POSIXt'
pretty(x, n = 5, min.n = n %/% 2, sep = " ", ...)
```

Arguments

<code>x</code>	an object of class "Date" or "POSIXt" (i.e., "POSIXct" or "POSIXlt").
<code>n</code>	integer giving the <i>desired</i> number of intervals.
<code>min.n</code>	nonnegative integer giving the <i>minimal</i> number of intervals.
<code>sep</code>	character string, serving as a separator for certain formats (e.g., between month and year).
<code>...</code>	further arguments for compatibility with the generic, ignored.

Value

A vector (of the suitable class) of locations, with attribute "labels" giving corresponding formatted character labels and attribute "format" giving the format specification that was used.

See Also

[pretty](#) for the default method.

Examples

```
pretty(Sys.Date())
pretty(Sys.time(), n = 10)

pretty(as.Date("2000-03-01")) # R 1.0.0 came in a leap year

## time ranges in diverse scales:
steps <- stats::setNames(
  c("10 secs", "1 min", "5 mins", "30 mins", "6 hours", "12 hours",
    "1 DSTday", "2 weeks", "1 month", "6 months", "1 year",
    "10 years", "50 years", "1000 years"))
x <- as.POSIXct("2002-02-02 02:02")
lapply(steps,
  function(s) {
    at <- pretty(seq(x, by = s, length.out = 2), n = 5)
    attr(at, "labels")
  })
```

ps.options

Auxiliary Function to Set/View Defaults for Arguments of postscript

Description

The auxiliary function `ps.options` can be used to set or view (if called without arguments) the default values for some of the arguments to [postscript](#).

`ps.options` needs to be called before calling `postscript`, and the default values it sets can be overridden by supplying arguments to `postscript`.

Usage

```
ps.options(..., reset = FALSE, override.check = FALSE)

setEPS(...)
setPS(...)
```

Arguments

<code>...</code>	arguments <code>onefile</code> , <code>family</code> , <code>title</code> , <code>fonts</code> , <code>encoding</code> , <code>bg</code> , <code>fg</code> , <code>width</code> , <code>height</code> , <code>horizontal</code> , <code>pointsize</code> , <code>paper</code> , <code>pagecentre</code> , <code>print.it</code> , <code>command</code> , <code>colormodel</code> and <code>fillOddEven</code> can be supplied. <code>onefile</code> , <code>horizontal</code> and <code>paper</code> are <i>ignored</i> for <code>setEPS</code> and <code>setPS</code> .
<code>reset</code>	logical: should the defaults be reset to their ‘factory-fresh’ values?
<code>override.check</code>	logical argument passed to check.options . See the Examples.

Details

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

For backwards compatibility argument `append` is accepted but ignored with a warning.

`setEPS` and `setPS` are wrappers to set defaults appropriate for figures for inclusion in documents (the default size is 7 inches square unless `width` or `height` is supplied) and for spooling to a PostScript printer respectively. For historical reasons the latter is the ultimate default.

Value

A named list of all the previous defaults. If `...` or `reset = TRUE` is supplied the result has the visibility flag turned off.

See Also

[postscript](#), [pdf.options](#)

Examples

```
ps.options(bg = "pink")
utils::str(ps.options())

### ---- error checking of arguments: ----
ps.options(width = 0:12, onefile = 0, bg = pi)
# override the check for 'width', but not 'bg':
ps.options(width = 0:12, bg = pi, override.check = c(TRUE,FALSE))
utils::str(ps.options())
ps.options(reset = TRUE) # back to factory-fresh
```

quartz

macOS Quartz Device

Description

`quartz` starts a graphics device driver for the macOS system. It supports plotting both to the screen (the default) and to various graphics file formats.

Usage

```
quartz(title, width, height, pointsize, family, antialias, type,
       file = NULL, bg, canvas, dpi)

quartz.options(..., reset = FALSE)

quartz.save(file, type = "png", device = dev.cur(), dpi = 100, ...)
```

Arguments

<code>title</code>	title for the Quartz window (applies to on-screen output only), default "Quartz %d". A C-style format for an integer will be substituted by the device number (see the <code>file</code> argument to pdf for further details).
<code>width</code>	the width of the plotting area in inches. Default 7.
<code>height</code>	the height of the plotting area in inches. Default 7.
<code>pointsize</code>	the default pointsize to be used. Default 12.
<code>family</code>	this is the family name of the font that will be used by the device. Default "Arial". This will be the base name of a font as shown in Font Book.
<code>antialias</code>	whether to use antialiasing. Default TRUE.
<code>type</code>	the type of output to use. See 'Details' for more information. Default "native".
<code>file</code>	an optional target for the graphics device. The default, NULL, selects a default name where one is needed. See 'Details' for more information.
<code>bg</code>	the initial background colour to use for the device. Default "transparent". An opaque colour such as "white" will normally be required on off-screen types that support transparency such as "png" and "tiff".
<code>canvas</code>	canvas colour to use for an on-screen device. Default "white", and will be forced to be an opaque colour.
<code>dpi</code>	resolution of the output. The default (NA_real_) for an on-screen display defaults to the resolution of the main screen, and to 72 dpi otherwise. See 'Details'.
<code>...</code>	Any of the arguments to <code>quartz</code> except <code>file</code> .
<code>reset</code>	logical: should the defaults be reset to their defaults?
<code>device</code>	device number to copy from.

Details

The defaults for all but one of the arguments of `quartz` are set by `quartz.options`: the 'Arguments' section gives the 'factory-fresh' defaults.

The Quartz graphics device supports a variety of output types. On-screen output types are "" or "native" or "Cocoa". Off-screen output types produce output files and utilize the `file` argument. `type = "pdf"` gives PDF output. The following bitmap formats may be supported (depending on the OS version): "png", "jpeg", "jpg", "jpeg2000", "tif", "tiff", "gif", "psd" (Adobe Photoshop), "bmp" (Windows bitmap), "sgi" and "pict".

The `file` argument is used for off-screen drawing. The actual file is only created when the device is closed (e.g., using `dev.off()`). For the bitmap devices, the page number is substituted if a C integer format is included in the character string, e.g. `Rplot%03d.png`. (Depending on the platform, the result should be less than `PATH_MAX` characters long, and may be truncated if not. See [pdf](#) for further details.) If a `file` argument is not supplied, the default is `Rplots.pdf` or `Rplot%03d.type`. Tilde expansion (see [path.expand](#)) is done.

If a device-independent R graphics font family is specified (e.g., via `par(family =)` in the graphics package), the Quartz device makes use of the Quartz font database (see `quartzFonts`) to convert the R graphics font family to a Quartz-specific font family description. The default conversions are (MonoType TrueType versions of) Helvetica for sans, Times-Roman for serif and Courier for mono.

On-screen devices are launched with a semi-transparent canvas. Once a new plot is created, the canvas is first painted with the `canvas` colour and then the current background colour (which can

quartzFonts

*Quartz Fonts Setup***Description**

These functions handle the translation of a device-independent R graphics font family name to a `quartz` font description.

They are only available on Unix-alikes, i.e, not on Windows, and typically used on the Mac.

Usage

```
quartzFont(family)
```

```
quartzFonts(...)
```

Arguments

<code>family</code>	a character vector containing the four PostScript font names for plain, bold, italic, and bold italic versions of a font family.
<code>...</code>	either character strings naming mappings to display, or new (named) mappings to define.

Details

A quartz device is created with a default font (see the documentation for `quartz`), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for `gpar` in the **grid** package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to quartz fonts. A list of mappings is maintained and can be modified by the user.

The `quartzFonts` function can be used to list existing mappings and to define new mappings. The `quartzFont` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font.

See Also

`quartz` for the default Mac graphics device.

Examples

```
if(.Platform$OS.type == "unix") { # includes macOS

  utils::str( quartzFonts() ) # a list(serif = .., sans = .., mono = ..)
  quartzFonts("mono")      # the list(mono = ..) sublist of quartzFonts()

## Not run:
## for East Asian locales you can use something like
quartzFonts(sans = quartzFont(rep("AppleGothic", 4)),
            serif = quartzFont(rep("AppleMyungjp", 4)))
## since the default fonts may well not have the glyphs needed
```

```
## End(Not run)
}
```

recordGraphics	<i>Record Graphics Operations</i>
----------------	-----------------------------------

Description

Records arbitrary code on the graphics engine display list. Useful for encapsulating calculations with graphical output that depends on the calculations. Intended *only* for expert use.

Usage

```
recordGraphics(expr, list, env)
```

Arguments

<code>expr</code>	object of mode expression or <code>call</code> or an unevaluated expression.
<code>list</code>	a list defining the environment in which <code>expr</code> is to be evaluated.
<code>env</code>	an environment specifying where R looks for objects not found in <code>list</code> .

Details

The code in `expr` is evaluated in an environment constructed from `list`, with `env` as the parent of that environment.

All three arguments are saved on the graphics engine display list so that on a device resize or copying between devices, the original evaluation environment can be recreated and the code can be re-evaluated to reproduce the graphical output.

Value

The value from evaluating `expr`.

Warning

This function is not intended for general use. Incorrect or improper use of this function could lead to unintended and/or undesirable results.

An example of acceptable use is querying the current state of a graphics device or graphics system setting and then calling a graphics function.

An example of improper use would be calling the `assign` function to performing assignments in the global environment.

See Also

[eval](#)

Examples

```
require(graphics)

plot(1:10)
# This rectangle remains 1inch wide when the device is resized
recordGraphics(
  {
    rect(4, 2,
        4 + diff(par("usr")[1:2])/par("pin")[1], 3)
  },
  list(),
  getNamespace("graphics"))
```

recordPlot	<i>Record and Replay Plots</i>
------------	--------------------------------

Description

Functions to save the current plot in an R variable, and to replay it.

Usage

```
recordPlot(load=NULL, attach=NULL)
replayPlot(x, reloadPkgs=FALSE)
```

Arguments

load	If not NULL, a character vector of package names, which are saved as part of the recorded plot.
attach	If not NULL, a character vector of package names, which are saved as part of the recorded plot.
x	A saved plot.
reloadPkgs	A logical indicating whether to reload and/or reattach any packages that were saved as part of the recorded plot.

Details

These functions record and replay the display list of the current graphics device. The returned object is of class "recordedplot", and `replayPlot` acts as a `print` method for that class.

The returned object is stored as a pairlist, but the usual methods for examining R objects such as `deparse` and `str` are liable to mislead.

Value

`recordPlot` returns an object of class "recordedplot".
`replayPlot` has no return value.

Warning

The format of recorded plots may change between R versions, so recorded plots should **not** be used as a permanent storage format for R plots.

As of R 3.3.0, it is possible (again) to replay a plot from another R session using, for example, `saveRDS` and `readRDS`. It is even possible to replay a plot from another R version, however, this will produce warnings, may produce errors, or something worse.

Note

Replay of a recorded plot may not produce the correct result (or may just fail) if the display list contains a call to `recordGraphics` which in turn contains an expression that calls code from a non-base package other than **graphics** or **grid**. The most well-known example of this is a plot drawn with the package **ggplot2**. One solution is to load the relevant package(s) before replaying the recorded plot. The `load` and `attach` arguments to `recordPlot` can be used to automate this - any packages named in `load` will be reloaded, via `loadNamespace`, and any packages named in `attach` will be reattached, via `library`, as long as `reloadPkgs` is `TRUE` in the call to `replayPlot`. This is only relevant when attempting to replay in one R session a plot that was recorded in a different R session.

See Also

The display list can be turned on and off using `dev.control`. Initially recording is on for screen devices, and off for print devices.

 rgb

RGB Color Specification

Description

This function creates colors corresponding to the given intensities (between 0 and `max`) of the red, green and blue primaries. The colour specification refers to the standard sRGB colorspace (IEC standard 61966).

An alpha transparency value can also be specified (as an opacity, so 0 means fully transparent and `max` means opaque). If `alpha` is not specified, an opaque colour is generated.

The `names` argument may be used to provide names for the colors.

The values returned by these functions can be used with a `col=` specification in graphics functions or in `par`.

Usage

```
rgb(red, green, blue, alpha, names = NULL, maxColorValue = 1)
```

Arguments

`red, blue, green, alpha`
 numeric vectors with values in $[0, M]$ where M is `maxColorValue`. When this is 255, the `red, blue, green, and alpha` values are coerced to integers in `0:255` and the result is computed most efficiently.

`names`
 character vector. The names for the resulting vector.

`maxColorValue`
 number giving the maximum of the color values range, see above.

Details

The colors may be specified by passing a matrix or data frame as argument `red`, and leaving `blue` and `green` missing. In this case the first three columns of `red` are taken to be the `red, green` and `blue` values.

Semi-transparent colors ($0 < \alpha < 1$) are supported only on some devices: at the time of writing on the `pdf, windows, quartz` and `X11 (type = "cairo")` devices and associated bitmap devices (`jpeg, png, bmp, tiff` and `bitmap`). They are supported by several third-party devices such as those in packages **Cairo**, **cairoDevice** and **JavaGD**. Only some of these devices support semi-transparent backgrounds.

Most other graphics devices plot semi-transparent colors as fully transparent, usually with a warning when first encountered.

NA values are not allowed for any of `red, blue, green` or `alpha`.

Value

A character vector with elements of 7 or 9 characters, beginning with `"#"` followed by the `red, blue, green` and optionally `alpha` values in hexadecimal (after rescaling to `0 ... 255`). The optional `alpha` values range from 0 (fully transparent) to 255 (opaque).

R does **not** use ‘premultiplied alpha’.

See Also

`col2rgb` for translating R colors to RGB vectors; `rainbow, hsv, hcl, gray`.

Examples

```
rgb(0, 1, 0)

rgb((0:15)/15, green = 0, blue = 0, names = paste("red", 0:15, sep = "."))

rgb(0, 0:12, 0, maxColorValue = 255) # integer input

ramp <- colorRamp(c("red", "white"))
rgb( ramp(seq(0, 1, length.out = 5)), maxColorValue = 255)
```

rgb2hsv

*RGB to HSV Conversion***Description**

rgb2hsv transforms colors from RGB space (red/green/blue) into HSV space (hue/saturation/value).

Usage

```
rgb2hsv(r, g = NULL, b = NULL, maxColorValue = 255)
```

Arguments

r vector of ‘red’ values in $[0, M]$, ($M = \text{maxColorValue}$) or 3-row RGB matrix.

g vector of ‘green’ values, or `NULL` when **r** is a matrix.

b vector of ‘blue’ values, or `NULL` when **r** is a matrix.

maxColorValue number giving the maximum of the RGB color values range. The default 255 corresponds to the typical 0:255 RGB coding as in `col2rgb()`.

Details

Value (brightness) gives the amount of light in the color.

Hue describes the dominant wavelength.

Saturation is the amount of Hue mixed into the color.

An HSV colorspace is relative to an RGB colorspace, which in R is sRGB, which has an implicit gamma correction.

Value

A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

Author(s)

R interface by Wolfram Fischer <wolfram@fischer-zim.ch>;

          all.equal(hsv3, rgb2hsv(rgb3/255, maxColorValue = 1)))

## A (simplified) pure R version -- originally by Wolfram Fischer --
## showing the exact algorithm:
rgb2hsvR <- function(rgb, gamma = 1, maxColorValue = 255)
{
  if(!is.numeric(rgb)) stop("rgb matrix must be numeric")
  d <- dim(rgb)
  if(d[1] != 3) stop("rgb matrix must have 3 rows")
  n <- d[2]
  if(n == 0) return(cbind(c(h = 1, s = 1, v = 1))[,0])
  rgb <- rgb/maxColorValue
  if(gamma != 1) rgb <- rgb ^ (1/gamma)

  ## get the max and min
  v <- apply( rgb, 2, max)
  s <- apply( rgb, 2, min)
  D <- v - s # range

  ## set hue to zero for undefined values (gray has no hue)
  h <- numeric(n)
  notgray <- ( s != v )

  ## blue hue
  idx <- (v == rgb[3,] & notgray )
  if (any (idx))
    h[idx] <- 2/3 + 1/6 * (rgb[1,idx] - rgb[2,idx]) / D[idx]
  ## green hue
  idx <- (v == rgb[2,] & notgray )
  if (any (idx))
    h[idx] <- 1/3 + 1/6 * (rgb[3,idx] - rgb[1,idx]) / D[idx]
  ## red hue
  idx <- (v == rgb[1,] & notgray )
  if (any (idx))
    h[idx] <- 1/6 * (rgb[2,idx] - rgb[3,idx]) / D[idx]

  ## correct for negative red
  idx <- (h < 0)
  h[idx] <- 1+h[idx]

  ## set the saturation
  s[! notgray] <- 0;
  s[notgray] <- 1 - s[notgray] / v[notgray]

  rbind( h = h, s = s, v = v )
}
```

```

}

## confirm the equivalence:
all.equal(rgb2hsv (rgb3),
          rgb2hsvR(rgb3), tolerance = 1e-14) # TRUE

```

savePlot

Save Cairo X11 Plot to File

Description

Save the current page of a cairo [X11](#) () device to a file.

Usage

```

savePlot(filename = paste0("Rplot.", type),
          type = c("png", "jpeg", "tiff", "bmp"),
          device = dev.cur())

```

Arguments

filename	filename to save to.
type	file type.
device	the device to save from.

Details

Only cairo-based X11 devices are supported.

This works by copying the image surface to a file. For PNG will always be a 24-bit per pixel PNG 'DirectClass' file, for JPEG the quality is 75% and for TIFF there is no compression.

For devices with buffering this copies the buffer's image surface, so works even if [dev.hold](#) has been called.

The plot is saved after rendering onto the canvas (default opaque white), so for the default `bg = "transparent"` the effective background colour is the canvas colour.

Value

Invisible `NULL`.

Note

There is a similar function of the same name but more types for windows devices on Windows: that has an additional argument `restoreConsole` which is only supported on Windows.

trans3d

*3D to 2D Transformation for Perspective Plots***Description**

Projection of 3-dimensional to 2-dimensional points using a 4x4 viewing transformation matrix. Mainly for adding to perspective plots such as [persp](#).

Usage

```
trans3d(x, y, z, pmat, continuous = FALSE, verbose = TRUE)
```

Arguments

x, y, z	numeric vectors of equal length, specifying points in 3D space.
pmat	a 4×4 <i>viewing transformation matrix</i> , suitable for projecting the 3D coordinates (x, y, z) into the 2D plane using homogeneous 4D coordinates (x, y, z, t) ; such matrices are returned by persp() .
continuous	logical flag specifying if the transformation should check if the transformed points are continuous in the sense that they do not jump over $a/0$ discontinuity. As these assume (x, y, z) to describe a continuous curve, the default must be false. In case of projecting such a curve however, setting continuous=TRUE may be advisable.
verbose	only for continuous=TRUE, indicates if a warning should be issued when points are cut off.

Value

a list with two components

x, y the projected 2d coordinates of the 3d input (x, y, z) .

See Also

[persp](#)

Examples

```
## See help(persp) {after attaching the 'graphics' package}
## -----

## Example for 'continuous = TRUE' (vs default):
require(graphics)
x <- -10:10/10 # [-1, 1]
y <- -16:16/16 # [-1, 1] ==> z = fxy := outer(x,y) is also in [-1,1]

p <- persp(x, y, fxy <- outer(x,y), phi = 20, theta = 15, r = 3, ltheta = -75,
           shade = 0.8, col = "green3", ticktype = "detailed")
## 5 axis-parallel auxiliary lines in x-y and y-z planes :
lines(trans3d(-.5 , y=-1:1, z=min(fxy), pmat=p), lty=2)
lines(trans3d( 0 , y=-1:1, z=min(fxy), pmat=p), lty=2)
lines(trans3d(-1:1, y= -.7, z=min(fxy), pmat=p), lty=2)
```

```

lines(trans3d( -1,  y= -.7, z=c(-1,1) ,  pmat=p), lty=2)
lines(trans3d( -1,  y=-1:1, z= -.5      ,  pmat=p), lty=2)
## 2 pillars to carry the horizontals below:
lines(trans3d(-.5 , y= -.7, z=c(-1,-.5), pmat=p), lwd=1.5, col="gray10")
lines(trans3d( 0   , y= -.7, z=c(-1,-.5), pmat=p), lwd=1.5, col="gray10")
## now some "horizontal rays" (going from center to very left or very right):
doHor <- function(x1, x2, z, CNT=FALSE, ...)
  lines(trans3d(x=seq(x1, x2, by=0.5), y= -0.7, z = z, pmat = p, continuous = CNT),
        lwd = 3, type="b", xpd=NA, ...)
doHor(-10, 0, z = -0.5, col = 2) # x in [-10, 0] -- to the very left : fine
doHor(-.5, 2, z = -0.52,col = 4) # x in [-0.5, 2] only {to the right} --> all fine
## but now, x in [-0.5, 20] -- "too far" ==> "wrap around" problem (without 'continuous=TRUE')
doHor(-.5, 20, z = -0.58, col = "steelblue", lty=2)
## but it is fixed with continuous = CNT = TRUE:
doHor(-.5, 20, z = -0.55, CNT=TRUE, col = "skyblue")

```

Type1Font

Type 1 and CID Fonts

Description

These functions are used to define the translation of a R graphics font family name to Type 1 or CID font descriptions, used by the [pdf](#) and [postscript](#) graphics devices.

Usage

```
Type1Font(family, metrics, encoding = "default")
```

```
CIDFont(family, cmap, cmapEncoding, pdfresource = "")
```

Arguments

family	a character string giving the name to be used internally for a Type 1 or CID-keyed font family. This needs to uniquely identify each family, so if you modify a family which is in use (see postscriptFonts) you need to change the family name.
metrics	a character vector of four or five strings giving paths to the afm (Adobe Font Metric) files for the font.
cmap	the name of a CMap file for a CID-keyed font.
encoding	for Type1Font, the name of an encoding file. Defaults to "default", which maps on Unix-alikes to "ISOLatin1.enc" and on Windows to "WinAnsi.enc". Otherwise, a file name in the 'enc' directory of the grDevices package, which is used if the path does not contain a path separator. An extension ".enc" can be omitted.
cmapEncoding	The name of a character encoding to be used with the named CMap file: strings will be translated to this encoding when written to the file.
pdfresource	A chunk of PDF code; only required for using a CID-keyed font on pdf; users should not be expected to provide this.

Details

For `Type1Fonts`, if four `.afm` files are supplied the fifth is taken to be `"Symbol.afm"`. Relative paths are taken relative to the directory `'R_HOME/library/grDevices/afm'`. The fifth (symbol) font must be in `AdobeSym` encoding. However, the glyphs in the first four fonts are referenced by name and any encoding given within the `.afm` files is not used.

The `.afm` files may be compressed with (or without) final extension `.gz`: the files which ship with R are installed as compressed files with this extension.

Glyphs in CID-keyed fonts are accessed by ID (number) and not by name. The `CMap` file maps encoded strings (usually in a MBCS) to IDs, so `cmap` and `cmapEncoding` specifications must match. There are no real bold or italic versions of CID fonts (bold/italic were very rarely used in traditional East Asian typography), and for the `pdf` device all four font faces will be identical. However, for the `postscript` device, bold and italic (and bold italic) are emulated.

CID-keyed fonts are intended only for use for the glyphs of East Asian languages, which are all monospaced and are all treated as filling the same bounding box. (Thus `plotmath` will work with such characters, but the spacing will be less carefully controlled than with Western glyphs.) The CID-keyed fonts do contain other characters, including a Latin alphabet: non-East-Asian glyphs are regarded as monospaced with half the width of East Asian glyphs. This is often the case, but sometimes Latin glyphs designed for proportional spacing are used (and may look odd). We strongly recommend that CID-keyed fonts are **only** used for East Asian glyphs.

Value

A list of class `"Type1Font"` or `"CIDFont"`.

See Also

[pdf](#), [postscript](#), [pdfFonts](#) and [postscriptFonts](#).

Examples

```
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
  c("CM_regular_10.afm", "CM_boldx_10.afm",
    "cmti10.afm", "cmbxti10.afm",
    "CM_symbol_10.afm"),
  encoding = "TeXtext.enc")

## Not run:
## This could be used by
postscript(family = CMitalic)
## or
postscriptFonts(CMitalic = CMitalic) # once in a session
postscript(family = "CMitalic", encoding = "TeXtext.enc")

## End(Not run)
```

windows

*Windows Graphics Devices***Description**

Available only on Windows. A graphics device is opened. For `windows`, `win.graph`, `x11` and `X11` this is a window on the current Windows display: the multiple names are for compatibility with other systems. `win.metafile` prints to a file and `win.print` to the Windows print system.

Usage

```
windows(width, height, pointsize, record, rescale, xpinch, ypinch,
        bg, canvas, gamma, xpos, ypos, buffered, title,
        restoreConsole, clickToConfirm, fillOddEven,
        family, antialias)
```

```
win.graph(width, height, pointsize)
```

```
win.metafile(filename = "", width = 7, height = 7, pointsize = 12,
             family, restoreConsole = TRUE,
             xpinch = NA_real_, ypinch = NA_real_)
```

```
win.print(width = 7, height = 7, pointsize = 12, printer = "",
         family, antialias, restoreConsole = TRUE)
```

Arguments

<code>width, height</code>	the (nominal) width and height of the canvas of the plotting window in inches. Default 7.
<code>pointsize</code>	the default pointsize of plotted text, interpreted as big points (1/72 inch). Values are rounded to the nearest integer: values less than or equal to zero are reset to 12, the default.
<code>record</code>	logical: sets the initial state of the flag for recording plots. Default <code>FALSE</code> .
<code>rescale</code>	character, one of <code>c("R", "fit", "fixed")</code> . Controls the action for resizing of the device. Default <code>"R"</code> . See the ‘Resizing options’ section.
<code>xpinch, ypinch</code>	double. Pixels per inch, horizontally and vertically. Default <code>NA_real_</code> , which means to take the value from Windows.
<code>bg</code>	color. The initial background color. Default <code>"transparent"</code> .
<code>canvas</code>	color. The color of the canvas which is visible when the background color is transparent. Should be a solid color (and any alpha value will be ignored). Default <code>"white"</code> .
<code>gamma</code>	gamma correction fudge factor. Colours in R are sRGB; if your monitor does not conform to sRGB, you might be able to improve things by tweaking this parameter to apply additional gamma correction to the RGB channels. By default 1 (no additional gamma correction).
<code>xpos, ypos</code>	integer. Position of the top left of the window, in pixels. Negative values are taken from the opposite edge of the monitor. Missing values (the default) mean

	take the default from the ‘ Rconsole ’ file, which in turn defaults to <code>xpos = -25</code> , <code>ypos = 0</code> : this puts the right edge of the window 25 pixels from the right edge of the monitor.
<code>buffered</code>	logical. Should the screen output be double-buffered? Default <code>TRUE</code> .
<code>title</code>	character string, up to 100 bytes. With the default <code>" "</code> , a suitable title is created internally. A C-style format for an integer will be substituted by the device number.
<code>filename</code>	the name of the output file: it will be an enhanced Windows metafile, usually given extension ‘ <code>.emf</code> ’ or ‘ <code>.wmf</code> ’. Up to 511 characters are allowed. The page number is substituted if an integer format is included in the character string (see pdf for further details) and tilde-expansion (see path.expand) is performed. (The result must be less than 600 characters long.) The default, <code>" "</code> , means the clipboard.
<code>printer</code>	The name of a printer as known to Windows. The default causes a dialog box to come up for the user to choose a printer.
<code>restoreConsole</code>	logical: see the ‘Details’ below. Defaults to <code>FALSE</code> for screen devices.
<code>clickToConfirm</code>	logical: if true confirmation of a new frame will be by clicking on the device rather than answering a problem in the console. Default <code>TRUE</code> .
<code>fillOddEven</code>	logical controlling the polygon fill mode: see polygon for details. Default <code>TRUE</code> .
<code>family</code>	A length-one character vector specifying the default font family. See section ‘Fonts’.
<code>antialias</code>	A length-one character vector, requesting control over font antialiasing. This is partially matched to <code>"default"</code> , <code>"none"</code> , <code>"cleartype"</code> or <code>"gray"</code> . See the ‘Fonts’ section.

Details

All these devices are implemented as variants of the same device.

All arguments of `windows` have defaults set by [windows.options](#): the defaults given in the arguments section are the defaults for the defaults. These defaults also apply to the internal values of `gamma`, `xpinch`, `ypinch`, `buffered`, `restoreConsole` and `antialias` for `win.graph`, `x11` and `X11`.

The size of a window is computed from information provided about the display: it depends on the system being configured accurately. By default a screen device asks Windows for the number of pixels per inch. This can be overridden (it is often wrong) by specifying `xpinch` and `ypinch`, most conveniently *via* [windows.options](#). For example, a 13.3 inch 1280x800 screen (a typical laptop display) was reported as 96 dpi even though it is physically about 114 dpi. These arguments may also be useful to match the scale of output to the size of a metafile (which otherwise depends on the system being configured accurately).

The different colours need to be distinguished carefully. Areas outside the device region are coloured in the Windows application background colour. The device region is coloured in the canvas colour. This is over-painted by the background colour of a plot when a new page is called for, but that background colour can be transparent (and is by default). One difference between setting the canvas colour and the background colour is that when a plot is saved the background colour is copied but the canvas colour is not. The argument `bg` sets the initial value of [par](#) (`"bg"`) in base graphics and [gpar](#) (`"fill"`) in grid graphics

Recorded plot histories are of class "SavedPlots". They have a `print` method, and a subset method. As the individual plots are of class "recordedplot" they can be replayed by printing them: see `recordPlot`. The active plot history is stored in variable `.SavedPlots` in the workspace.

When a screen device is double-buffered (the default) the screen is updated 100ms after last plotting call or every 500ms during continuous plotting. These times can be altered by setting `options("windowsTimeouts")` to a vector of two integers before opening the device.

Line widths as controlled by `par(lwd=)` are in multiples of 1/96inch. Multiples less than 1 are allowed, down to one pixel width.

For `win.metafile` only one plot is allowed per file, and Windows seems to disallow reusing the file. So the *only* way to allow multiple plots is to use a parametrized `filename` as in the example. If the `filename` is omitted (or specified as ""), the output is copied to the clipboard when the device is closed.

The `restoreConsole` argument is a temporary fix for a problem in the current implementation of several Windows graphics devices, and is likely to be removed in an upcoming release. If set to `FALSE`, the console will not receive the focus after the new device is opened.

There is support for semi-transparent colours of lines, fills and text on the screen devices. These work for saving (from the 'File' menu) to PDF, PNG, BMP, JPEG and TIFF, but will be ignored if saving to Metafile and PostScript. Limitations in the underlying Windows API mean that a semi-transparent object must be contained strictly within the device region (allowing for line widths and joins).

Value

A plot device is opened: nothing is returned to the R interpreter.

Resizing options

If a screen device is re-sized, the default behaviour ("R") is to redraw the plot(s) as if the new size had been specified originally. Using "fit" will rescale the existing plot(s) to fit the new device region, preserving the aspect ratio. Using "fixed" will leave the plot size unchanged, adding scrollbars if part of the plot is obscured.

A graphics window will never be created at more than 85% of the screen width or height, but can be resized to a larger size. For the first two `rescale` options the width and height are rescaled proportionally if necessary, and if `rescale = "fit"` the plot(s) are rescaled accordingly. If `rescale = "fixed"` the initially displayed portion is selected within these constraints, separately for width and height. In MDI mode, the limit is 85% of the MDI client region.

Using `strwidth` or `strheight` after a window has been rescaled (when using "fit") gives dimensions in the original units, but only approximately as they are derived from the metrics of the rescaled fonts (which are in integer sizes)

The displayed region may be bigger than the 'paper' size, and area(s) outside the 'paper' are coloured in the Windows application background colour. Graphics parameters such as "din" refer to the scaled plot if rescaling is in effect.

Fonts

The fonts used for text drawn in a Windows device may be controlled in two ways. The file '`R_HOME\etc\Rdevga`' can be used to specify mappings for `par(font=)` (or the **grid** equivalent). Alternatively, a font family can be specified by a non-empty `family` argument (or by e.g. `par(family=)` in the graphics package) and this will be used for fonts 1:4 via the Windows font database (see `windowsFonts`).

How the fonts look depends on the antialiasing settings, both through the `antialias` argument and the machine settings. These are hints to Windows GDI that may not be able to be followed, but `antialias = "none"` should ensure that no antialiasing is used. For a screen device the default depends on the machine settings: it will be `"cleartype"` if that has been enabled. Note that the greyscale antialiasing that is used only for small fonts (below about 9 pixels, around 7 points on a typical display).

When accessing a system through Remote Desktop, both the Remote Desktop settings *and* the user's local account settings are relevant to whether antialiasing is used.

Some fonts are intended only to be used with ClearType antialiasing, for example the Meiryo Japanese font.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *[R Internals](#)*.

- The default device size is 7 inches square, although this is often incorrectly implemented by Windows: see 'Details'.
- Font sizes are in big points.
- The default font family is Arial.
- Line widths are as a multiple of 1/96 inch, with a minimum of one pixel.
- The minimum radius of a circle is 1 pixel.
- `pch = "."` with `cex = 1` corresponds to a rectangle of sides the larger of one pixel and 0.01 inch.
- Colours are interpreted via the unprofiled colour mapping of the graphics card – this is *assumed* to conform to sRGB.

Note

`x11()`, `X11()` and `win.graph()` are simple wrappers calling `windows()`, and mainly exist for compatibility reasons.

Further, `x11()` and `X11()` have their own help page for Unix-alikes (where they also have more arguments).

See Also

`windowsFonts`, `savePlot`, `bringToTop`, `Devices`, `pdf`, `x11` for Unix-alikes.

Examples

```
## Not run: ## A series of plots written to a sequence of metafiles
if(.Platform$OS.type == "windows")
  win.metafile("Rplot%02d.wmf", pointsize = 10)

## End(Not run)
```

windows.options	<i>Auxiliary Function to Set/View Defaults for Arguments of windows()</i>
-----------------	---

Description

Only available on Windows, the auxiliary function `windows.options` can be used to set or view (if called without arguments) the default values for the arguments of `windows`.

`windows.options` needs to be called before calling `windows`, and the default values it sets can be overridden by supplying arguments to `windows`.

Usage

```
windows.options(..., reset = FALSE)
```

Arguments

<code>...</code>	arguments <code>width</code> , <code>height</code> , <code>pointsize</code> , <code>record</code> , <code>rescale</code> , <code>xpinch</code> , <code>ypinch</code> , <code>bg</code> , <code>canvas</code> , <code>gamma</code> , <code>xpos</code> , <code>ypos</code> , <code>buffered</code> , <code>restoreConsole</code> , <code>clickToConfirm</code> , <code>title</code> , <code>fillOddEven</code> and <code>antialias</code> can be supplied.
<code>reset</code>	logical: should the defaults be reset to their ‘factory-fresh’ values?

Details

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

Option `antialias` applies to screen devices (`windows`, `win.graph`, `X11` and `x11`). There is a separate option, `bitmap.aa.win`, for bitmap devices with `type = "windows"`.

Value

A named list of all the defaults. If any arguments are supplied the returned values are the old values and the result has the visibility flag turned off.

See Also

`windows`, `ps.options`.

Examples

```
## Not run:
## put something like this in your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
  function(...)
    grDevices::windows.options(width = 8, height = 6,
                              xpos = 0, pointsize = 10,
                              bitmap.aa.win = "cleartype"))

## End(Not run)
```

windowsFonts	<i>Windows Fonts</i>
--------------	----------------------

Description

These functions handle the translation of a device-independent R graphics font family name to a windows font description and are available only on Windows.

Usage

```
windowsFont(family)

windowsFonts(...)
```

Arguments

<code>family</code>	a character vector containing the font family name ("TT" as the first two characters indicates a TrueType font).
<code>...</code>	either character strings naming mappings to display, or new (named) mappings to define.

Details

A windows device is created with a default font (see the documentation for `windows`), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for `"family"` in `par` and for `"fontfamily"` in `gpar` in the **grid** package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to windows fonts. A list of mappings is maintained and can be modified by the user.

The `windowsFonts` function can be used to list existing mappings and to define new mappings. The `windowsFont` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: `"sans"` for a sans-serif font, `"serif"` for a serif font and `"mono"` for a monospaced font.

These mappings will only be used if the current font face is 1 (plain), 2 (bold), 3 (italic), or 4 (bold italic).

See Also

Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  windowsFonts()
  windowsFonts("mono")
})

## Not run: ## set up for Japanese: needs the fonts installed
windows() # make sure we have the right device type (available on Windows only)
Sys.setlocale("LC_ALL", "ja")
windowsFonts(JP1 = windowsFont("MS Mincho"),
             JP2 = windowsFont("MS Gothic"),
```

```

JP3 = windowsFont("Arial Unicode MS"))
plot(1:10)
text(5, 2, "\u{4E10}\u{4E00}\u{4E01}", family = "JP1")
text(7, 2, "\u{4E10}\u{4E00}\u{4E01}", family = "JP1", font = 2)
text(5, 1.5, "\u{4E10}\u{4E00}\u{4E01}", family = "JP2")
text(9, 2, "\u{5100}", family = "JP3")

## End(Not run)

```

x11

X Window System Graphics (X11)

Description

on Windows, the `X11()` and `x11()` functions are simple wrappers to `windows()` for historical compatibility convenience: Calling `x11()` or `X11()` would work in most cases to open an interactive graphics device.

In R versions before 3.6.0, the Windows version had a shorter list of formal arguments. Consequently, calls to `X11(*)` with arguments should *name* them for back compatibility.

Almost all information below does *not* apply on Windows.

on Unix-alikes `X11` starts a graphics device driver for the X Window System (version 11). This can only be done on machines/accounts that have access to an X server.

`x11` is recognized as a synonym for `X11`.

The R function is a wrapper for two devices, one based on Xlib (<https://en.wikipedia.org/wiki/Xlib>) and one using cairographics (<https://www.cairographics.org>).

Usage

```

X11(display = "", width, height, pointsize, gamma, bg, canvas,
     fonts, family, xpos, ypos, title, type, antialias, symbolfamily)

X11.options(..., reset = FALSE)

```

Arguments

<code>display</code>	the display on which the graphics window will appear. The default is to use the value in the user's environment variable <code>DISPLAY</code> . This is ignored (with a warning) if an X11 device is already open on another display.
<code>width,height</code>	the width and height of the plotting window, in inches. If NA, taken from the resources and if not specified there defaults to 7 inches. See also 'Resources'.
<code>pointsize</code>	the default pointsize to be used. Defaults to 12.
<code>gamma</code>	gamma correction fudge factor. Colours in R are sRGB; if your monitor does not conform to sRGB, you might be able to improve things by tweaking this parameter to apply additional gamma correction to the RGB channels. By default 1 (no additional gamma correction).
<code>bg</code>	colour, the initial background colour. Default "transparent".
<code>canvas</code>	colour. The colour of the canvas, which is visible only when the background colour is transparent. Should be an opaque colour (and any alpha value will be ignored). Default "white".

<code>fonts</code>	for <code>type = "Xlib"</code> only: X11 font description strings into which weight, slant and size will be substituted. There are two, the first for fonts 1 to 4 and the second for font 5, the symbol font. See section ‘Fonts’.
<code>family</code>	The default family: a length-one character string. This is primarily intended for cairo-based devices, but for <code>type = "Xlib"</code> , the <code>X11Fonts()</code> database is used to map family names to <code>fonts</code> (and this argument takes precedence over that one).
<code>xpos, ypos</code>	integer: initial position of the top left corner of the window, in pixels. Negative values are from the opposite corner, e.g. <code>xpos = -100</code> says the top right corner should be 100 pixels from the right edge of the screen. If <code>NA</code> (the default), successive devices are cascaded in 20 pixel steps from the top left. See also ‘Resources’.
<code>title</code>	character string, up to 100 bytes. With the default, "", a suitable title is created internally. A C-style format for an integer will be substituted by the device number (see the <code>file</code> argument of <code>df</code> for further details). How non-ASCII titles are handled is implementation-dependent.
<code>type</code>	character string, one of "Xlib", "cairo", "nbcairo" or "dbcairo". Only the first will be available if the system was compiled without support for cairographics. The default is "cairo" where R was built using pangocairo (often not the case on macOS), otherwise "Xlib".
<code>antialias</code>	for cairo types, the type of anti-aliasing (if any) to be used. One of <code>c("default", "none", "gray", "subpixel")</code> .
<code>symbolfamily</code>	for cairo-based devices only: a length-one character string that specifies the font family to be used as the "symbol" font (e.g., for <code>plotmath</code> output). The default value is "default", which means that R will choose a default "symbol" font based on the graphics device capabilities.
<code>reset</code>	logical: should the defaults be reset to their defaults?
<code>...</code>	Any of the arguments to <code>X11</code> , plus <code>colortype</code> and <code>maxcubsize</code> (see section ‘Colour Rendering’).

Details

The defaults for all of the arguments of `X11` are set by `X11.options`: the ‘Arguments’ section gives the ‘factory-fresh’ defaults.

The initial size and position are only hints, and may not be acted on by the window manager. Also, some systems (especially laptops) are set up to appear to have a screen of a different size to the physical screen.

Option `type` selects between two separate devices: R can be built with support for neither, `type = "Xlib"` or both. Where both are available, types "cairo", "nbcairo" and "dbcairo" offer

- antialiasing of text and lines.
- translucent colours.
- scalable text, including to sizes like 4.5 pt.
- full support for UTF-8, so on systems with suitable fonts you can plot in many languages on a single figure (and this will work even in non-UTF-8 locales). The output should be locale-independent.

The font selection is handled by Pango (usually *via* `fontconfig`) or `fontconfig` (on macOS and perhaps elsewhere). The results depend on the fonts installed on the system running R – setting the environment variable `FC_DEBUG` to 1 normally allows some tracing of the selection process.

This works best when high-quality scalable fonts are installed, usually in Type 1 or TrueType formats: see *R Installation and Administration* for advice on how to obtain and install such fonts. At present the best rendering (including using kerning) will be achieved with TrueType fonts: see <https://www.freedesktop.org/software/fontconfig/fontconfig-user.html> for ways to set up your system to prefer them. The default family ("Helvetica") is likely not to use kerning: alternatives which should if you have them installed are "Arial", "DejaVu Sans" and "Liberation Sans" (and perhaps "FreeSans"). For those who prefer fonts with serifs, try "Times New Roman", "DejaVu Serif" and "Liberation Serif". To match LaTeX text, use something like "CM Roman".

Fedora systems from version 31 on do not like the default "symbol" font family for rendering symbols (e.g., `plotmath`). For those systems, users should specify a different font via `symbolfamily`. The default can also be changed via `X11.options`.

Problems with incorrect rendering of symbols (e.g., of `quote(pi)` and `expression(10^degree)`) have been seen on Linux systems which have the Wine symbol font installed – `fontconfig` then prefers this and misinterprets its encoding. Adding the following lines to `~/.fonts.conf` or `/etc/fonts/local.conf` may circumvent this problem by preferring the URW Type 1 symbol font.

```
<fontconfig>
<match target="pattern">
  <test name="family"><string>Symbol</string></test>
  <edit name="family" mode="prepend" binding="same">
    <string>Standard Symbols L</string>
  </edit>
</match>
</fontconfig>
```

A test for this is to run at the command line `fc-match Symbol`. If that shows `symbol.ttf` that may be the Wine symbol font – use `locate symbol.ttf` to see if it is found from a directory with 'wine' in the name.

Resources

The standard X11 resource `geometry` can be used to specify the window position and/or size, but will be overridden by values specified as arguments or non-NA defaults set in `X11.options`. The class looked for is `R_x11`. Note that the resource specifies the width and height in pixels and not in inches. See for example 'man X' (or <https://www.x.org/releases/current/>). An example line in `~/.Xresources` might be

```
R_x11*geometry: 900x900-0+0
```

which specifies a 900 x 900 pixel window at the top right of the screen.

Colour Rendering

X11 supports several 'visual' types, and nowadays almost all systems support 'truecolor' which X11 will use by default. This uses a direct specification of any RGB colour up to the depth supported (usually 8 bits per colour). Other visuals make use of a palette to support fewer colours, only grays or even only black/white. The palette is shared between all X11 clients, so it can be necessary to limit the number of colours used by R.

The default for `type = "Xlib"` is to use the best possible colour model for the visual of the X11 server: these days this will almost always be 'truecolor'. This can be overridden by the `colortype` argument of `X11.options`. **Note:** All X11 and `type = "Xlib"` `bmp`, `jpeg`, `png` and `tiff` devices share a `colortype` which is set when the first device to be opened. To change the `colortype` you need to close *all* open such devices, and then use `X11.options(colortype = )`.

The `colortype` types are tried in the order `"true"`, `"pseudo"`, `"gray"` and `"mono"` (black or white only). The values `"pseudo"` and `"pseudo.cube"` provide two colour strategies for a pseudocolor visual. The first strategy provides on-demand colour allocation which produces exact colours until the colour resources of the display are exhausted (when plotting will fail). The second allocates (if possible) a standard colour cube, and requested colours are approximated by the closest value in the cube.

With `colortype` equal to `"pseudo.cube"` or `"gray"` successively smaller palettes are tried until one is completely allocated. If allocation of the smallest attempt fails the device will revert to `"mono"`. For `"gray"` the search starts at 256 grays for a display with depth greater than 8, otherwise with half the available colours. For `"pseudo.cube"` the maximum cube size is set by `X11.options(maxcolorsize = )` and defaults to 256. With that setting the largest cube tried is 4 levels each for RGB, using 64 colours in the palette.

The cairographics-based devices most likely only work (or work correctly) with 'TrueColor' visuals, although in principle this depends on the cairo installation: a warning is given if any other visual is encountered.

`type = "Xlib"` supports 'TrueColor', 'PseudoColor', 'GrayScale', `StaticGray` and `MonoChrome` visuals: 'StaticColor' and 'DirectColor' visuals are handled only in black/white.

Anti-aliasing

Anti-aliasing is only supported for cairographics-based devices, and applies to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for `image` plots, and so is never used for fills.

`antialias = "default"` is in principle platform-dependent, but seems most often equivalent to `antialias = "gray"`.

Conventions

This section describes the implementation of the conventions for graphics devices set out in *R Internals*.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths in 1/96 inch, minimum one pixel for `type = "Xlib"`, 0.01 otherwise.
- For `type = "Xlib"` circle radii are in pixels with minimum one.
- Colours are interpreted by the X11 server, which is *assumed* to conform to sRGB.

Warning

Support for all the Unix devices is optional, so in packages `X11 ( )` should be used conditionally after checking `capabilities("X11")`.

Examples

```
## Not run:
if(.Platform$OS.type == "unix") { # Only on unix-alikes, possibly Mac,
## put something like this in your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::X11.options(width = 8, height = 6, xpos = 0,
                                                pointsize = 10))
}
## End(Not run)
```

X11Fonts	<i>X11 Fonts</i>
----------	------------------

Description

These functions handle the translation of a device-independent R graphics font family name to an X11 font description on Unix-alike platforms.

Usage

```
X11Font(font)

X11Fonts(...)
```

Arguments

<code>font</code>	a character string containing an X11 font description.
<code>...</code>	either character strings naming mappings to display, or new (named) mappings to define.

Details

These functions apply only to an [X11](#) device with `type = "Xlib"` – X11 (`type = "cairo"`) uses a different mechanism to select fonts.

Such a device is created with a default font (see the documentation for [X11](#)), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for `"family"` in [par](#) and for `"fontfamily"` in [gpar](#) in the **grid** package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to X11 fonts. A list of mappings is maintained and can be modified by the user.

The `X11Fonts` function can be used to list existing mappings and to define new mappings. The `X11Font` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: `"sans"` for a sans-serif font, `"serif"` for a serif font and `"mono"` for a monospaced font. Further mappings are provided for `"Helvetica"` (the device default), `"Times"`, `"CyrHelvetica"`, `"CyrTimes"` (versions of these fonts with Cyrillic support, at least on Linux), `"Arial"` (on some platforms including macOS) and `"Mincho"` (a CJK font).

matrix or data.frame with two or more columns: the first is assumed to contain the x values and the second the y values. *Note* that is also true if x has columns named "x" and "y"; these names will be irrelevant here.

In any other case, the x argument is coerced to a vector and returned as y component where the resulting x is just the index vector 1:n. In this case, the resulting xlab component is set to "Index" (if setLab is true as by default).

If x (after transformation as above) inherits from class "POSIXt" it is coerced to class "POSIXct".

Value

A list with the components

x	numeric (i.e., "double") vector of abscissa values.
y	numeric vector of the same length as x.
xlab	character(1) or NULL, the 'label' of x.
ylab	character(1) or NULL, the 'label' of y.

See Also

`plot.default`, `lines`, `points` and `lowess` are examples of functions which use this mechanism.

Examples

```
ff <- stats::fft(1:9)
xy.coords(ff)
xy.coords(ff, xlab = "fft") # labels "Re(fft)", "Im(fft)"

with(cars, xy.coords(dist ~ speed, NULL)$xlab ) # = "speed"

xy.coords(1:3, 1:2, recycle = TRUE) # otherwise error "lengths differ"
xy.coords(-2:10, log = "y")
##> xlab: "Index"  \\ warning: 3 y values <= 0 omitted ..
op <- options(warn = 2) # ==> warnings would be errors, we suppress the one "we know":
suppressWarnings(xy.coords(-2:10, log = "y"), classes="log_le_0") -> xy
options(op) # revert
stopifnot(is.list(xy), identical(1:13 + 0, xy$x),
          identical(c(rep(NA, 3), 1:10 + 0), xy$y))
```

xyTable

Multiplicities of (x,y) Points, e.g., for a Sunflower Plot

Description

Given (x,y) points, determine their multiplicity – checking for equality only up to some (crude kind of) noise. Note that this is special kind of 2D binning.

Usage

```
xyTable(x, y = NULL, digits)
```

Arguments

<code>x, y</code>	numeric vectors of the same length; alternatively other (x, y) argument combinations as allowed by <code>xyz.coords(x, y)</code> .
<code>digits</code>	integer specifying the significant digits to be used for determining equality of coordinates. These are compared after rounding them via <code>signif(*, digits)</code> .

Value

A list with three components of same length,

<code>x</code>	x coordinates, rounded and sorted.
<code>y</code>	y coordinates, rounded (and sorted within x).
<code>number</code>	multiplicities (positive integers); i.e., <code>number[i]</code> is the multiplicity of <code>(x[i], y[i])</code> .

Note

Missing values in the coordinates are counted towards the multiplicities. The sum of the multiplicities will equal the number of coordinates.

See Also

`sunflowerplot` which typically uses `xyTable()`; `signif`.

Examples

```
xyTable(iris[, 3:4], digits = 6)

## If missing coordinates exist, they are also counted
iris2 <- iris[1:10, 3:4]
iris2[4, 2] <- NA
iris2[c(3, 5), ] <- NA
xyTable(iris2)

## Discretized uncorrelated Gaussian:

xy <- data.frame(x = round(sort(stats::rnorm(100))), y = stats::rnorm(100))
xyTable(xy, digits = 1)
```

xyz.coords

Extracting Plotting Structures

Description

Utility for obtaining consistent x, y and z coordinates and labels for three dimensional (3D) plots.

Usage

```
xyz.coords(x, y = NULL, z = NULL,
           xlab = NULL, ylab = NULL, zlab = NULL,
           log = NULL, recycle = FALSE, setLab = TRUE)
```

Arguments

<code>x, y, z</code>	the x, y and z coordinates of a set of points. Both <code>y</code> and <code>z</code> can be left at <code>NULL</code> . In this case, an attempt is made to interpret <code>x</code> in a way suitable for plotting. If the argument is a formula <code>zvar ~ xvar + yvar</code> , <code>xvar</code> , <code>yvar</code> and <code>zvar</code> are used as x, y and z variables; if the argument is a list containing components <code>x</code> , <code>y</code> and <code>z</code> , these are assumed to define plotting coordinates; if the argument is a matrix or <code>data.frame</code> with three or more columns, the first is assumed to contain the x values, the 2nd the y ones, and the 3rd the z ones – independently of any column names that <code>x</code> may have. Alternatively two arguments <code>x</code> and <code>y</code> can be provided (leaving <code>z = NULL</code>). One may be real, the other complex; in any other case, the arguments are coerced to vectors and the values plotted against their indices.
<code>xlab, ylab, zlab</code>	names for the x, y and z variables to be extracted.
<code>log</code>	character, "x", "y", "z" or combinations. Sets negative values to <code>NA</code> and gives a warning of class "log_le_0".
<code>recycle</code>	logical; if TRUE, recycle (rep) the shorter ones of <code>x</code> , <code>y</code> or <code>z</code> if their lengths differ.
<code>setLab</code>	logical indicating if the resulting <code>xlab</code> and <code>ylab</code> should be constructed from the "kind" of (<code>x</code> , <code>y</code>); otherwise, the arguments <code>xlab</code> and <code>ylab</code> are used.

Value

A list with the components

<code>x</code>	numeric (i.e., double) vector of abscissa values.
<code>y</code>	numeric vector of the same length as <code>x</code> .
<code>z</code>	numeric vector of the same length as <code>x</code> .
<code>xlab</code>	character(1) or <code>NULL</code> , the axis label of <code>x</code> .
<code>ylab</code>	character(1) or <code>NULL</code> , the axis label of <code>y</code> .
<code>zlab</code>	character(1) or <code>NULL</code> , the axis label of <code>z</code> .

[xy.coords](#) for 2D.

Examples

```
xyz.coords(data.frame(10*1:9, -4), y = NULL, z = NULL)

xyz.coords(1:5, stats::fft(1:5), z = NULL, xlab = "X", ylab = "Y")

y <- 2 * (x2 <- 10 + (x1 <- 1:10))
xyz.coords(y ~ x1 + x2, y = NULL, z = NULL)

xyz.coords(data.frame(x = -1:9, y = 2:12, z = 3:13), y = NULL, z = NULL,
  log = "xy")
```

```
##> Warning message: 2 x values <= 0 omitted ...  
## Suppress this specific warning:  
suppressWarnings(xyz.coords(x = -1:9, y = 2:12, z = 3:13, log = "xy"),  
  classes = "log_le_0")
```

Chapter 5

The `graphics` package

<code>graphics-package</code>	<i>The R Graphics Package</i>
-------------------------------	-------------------------------

Description

R functions for base graphics

Details

This package contains functions for ‘base’ graphics. Base graphics are traditional S-like graphics, as opposed to the more recent [grid](#) graphics.

For a complete list of functions with individual help pages, use `library(help = "graphics")`.

Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

abline

*Add Straight Lines to a Plot***Description**

This function adds one or more straight lines through the current plot.

Usage

```
abline(a = NULL, b = NULL, h = NULL, v = NULL, reg = NULL,
       coef = NULL, untf = FALSE, ...)
```

Arguments

<code>a, b</code>	the intercept and slope, single values.
<code>untf</code>	logical asking whether to <i>untransform</i> . See ‘Details’.
<code>h</code>	the y-value(s) for horizontal line(s).
<code>v</code>	the x-value(s) for vertical line(s).
<code>coef</code>	a vector of length two giving the intercept and slope.
<code>reg</code>	an object with a <code>coef</code> method. See ‘Details’.
<code>...</code>	graphical parameters such as <code>col</code> , <code>lty</code> and <code>lwd</code> (possibly as vectors: see ‘Details’) and <code>xpd</code> and the line characteristics <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> .

Details

Typical usages are

```
abline(a, b, ...)
abline(h =, ...)
abline(v =, ...)
abline(coef =, ...)
abline(reg =, ...)
```

The first form specifies the line in intercept/slope form (alternatively `a` can be specified on its own and is taken to contain the slope and intercept in vector form).

The `h=` and `v=` forms draw horizontal and vertical lines at the specified coordinates.

The `coef` form specifies the line by a vector containing the slope and intercept.

`reg` is a regression object with a `coef` method. If this returns a vector of length 1 then the value is taken to be the slope of a line through the origin, otherwise, the first 2 values are taken to be the intercept and slope.

If `untf` is true, and one or both axes are log-transformed, then a curve is drawn corresponding to a line in original coordinates, otherwise a line is drawn in the transformed coordinate system. The `h` and `v` parameters always refer to original coordinates.

The [graphical parameters](#) `col`, `lty` and `lwd` can be specified; see [par](#) for details. For the `h=` and `v=` usages they can be vectors of length greater than one, recycled as necessary.

Specifying an `xpd` argument for clipping overrides the global `par("xpd")` setting used otherwise.

```

arrows

Add Arrows to a Plot

Description

Draw arrows between pairs of points.

Usage

```
arrows(x0, y0, x1 = x0, y1 = y0, length = 0.25, angle = 30,
       code = 2, col = par("fg"), lty = par("lty"),
       lwd = par("lwd"), ...)
```

Arguments

<code>x0, y0</code>	coordinates of points from which to draw.
<code>x1, y1</code>	coordinates of points to which to draw. At least one must be supplied
<code>length</code>	length of the edges of the arrow head (in inches).
<code>angle</code>	angle from the shaft of the arrow to the edge of the arrow head.
<code>code</code>	integer code, determining <i>kind</i> of arrows to be drawn.
<code>col, lty, lwd</code>	graphical parameters , possible vectors. NA values in <code>col</code> cause the arrow to be omitted.
<code>...</code>	graphical parameters such as <code>xpd</code> and the line characteristics <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> : see par .

Details

For each `i`, an arrow is drawn between the point `(x0[i], y0[i])` and the point `(x1[i], y1[i])`. The coordinate vectors will be recycled to the length of the longest.

If `code = 1` an arrowhead is drawn at `(x0[i], y0[i])` and if `code = 2` an arrowhead is drawn at `(x1[i], y1[i])`. If `code = 3` a head is drawn at both ends of the arrow. Unless `length = 0`, when no head is drawn.

The [graphical parameters](#) `col`, `lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

The direction of a zero-length arrow is indeterminate, and hence so is the direction of the arrowheads. To allow for rounding error, arrowheads are omitted (with a warning) on any arrow of length less than 1/1000 inch.

Note

The first four arguments in the comparable S function are named `x1`, `y1`, `x2`, `y2`.

[segments](#) to draw segments.

Examples

```
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main = "arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1) # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col = 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col = "pink")
```

assocplot	Association Plots
-----------	-------------------

Description

Produce a Cohen-Friendly association plot indicating deviations from independence of rows and columns in a 2-dimensional contingency table.

Usage

```
assocplot(x, col = c("black", "red"), space = 0.3,
          main = NULL, xlab = NULL, ylab = NULL)
```

Arguments

<code>x</code>	a two-dimensional contingency table in matrix form.
<code>col</code>	a character vector of length two giving the colors used for drawing positive and negative Pearson residuals, respectively.
<code>space</code>	the amount of space (as a fraction of the average rectangle width and height) left between each rectangle.
<code>main</code>	overall title for the plot.
<code>xlab</code>	a label for the x axis. Defaults to the name (if any) of the row dimension in <code>x</code> .
<code>ylab</code>	a label for the y axis. Defaults to the name (if any) of the column dimension in <code>x</code> .

Details

For a two-way contingency table, the signed contribution to Pearson's χ^2 for cell i, j is $d_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}}$, where f_{ij} and e_{ij} are the observed and expected counts corresponding to the cell. In the Cohen-Friendly association plot, each cell is represented by a rectangle that has (signed) height proportional to d_{ij} and width proportional to $\sqrt{e_{ij}}$, so that the area of the box is proportional to the difference in observed and expected frequencies. The rectangles in each row are positioned relative to a baseline indicating independence ($d_{ij} = 0$). If the observed frequency of a cell is greater than the expected one, the box rises above the baseline and is shaded in the color specified by the first element of `col`, which defaults to black; otherwise, the box falls below the baseline and is shaded in the color specified by the second element of `col`, which defaults to red.

A more flexible and extensible implementation of association plots written in the grid graphics system is provided in the function `assoc` in the contributed package **vcd** (Meyer, Zeileis, and Hornik 2006).

Axis

Generic Function to Add an Axis to a Plot

Description

Generic function to add a suitable axis to the current plot.

Usage

```
Axis(x = NULL, at = NULL, ..., side, labels = NULL)
```

Arguments

<code>x</code>	an object which indicates the range over which an axis should be drawn
<code>at</code>	the points at which tick-marks are to be drawn.
<code>side</code>	an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
<code>labels</code>	this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tick points. If this is specified as a character or expression vector, <code>at</code> should be supplied and they should be the same length.
<code>...</code>	arguments to be passed to methods and perhaps then to axis .

Details

This is a generic function. It works in a slightly non-standard way: if `x` is supplied and non-NULL it dispatches on `x`, otherwise if `at` is supplied and non-NULL it dispatches on `at`, and the default action is to call [axis](#), omitting argument `x`.

The idea is that for plots for which either or both of the axes are numerical but with a special interpretation, the standard plotting functions (including [boxplot](#), [contour](#), [coplot](#), [filled.contour](#), [pairs](#), [plot.default](#), [rug](#) and [stripchart](#)) will set up user coordinates and `Axis` will be called to label them appropriately.

There are "Date" and "POSIXt" methods which can pass an argument `format` on to the appropriate `axis` method (see [axis.POSIXct](#)).

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also

[axis](#) (which is eventually called from all `Axis()` methods) in package **graphics**.

axis

*Add an Axis to a Plot***Description**

Adds an axis to the current plot, allowing the specification of the side, position, labels, and other options.

Usage

```
axis(side, at = NULL, labels = TRUE, tick = TRUE, line = NA,
      pos = NA, outer = FALSE, font = NA, lty = "solid",
      lwd = 1, lwd.ticks = lwd, col = NULL, col.ticks = NULL,
      hadj = NA, padj = NA, gap.axis = NA, ...)
```

Arguments

side	an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
at	the points at which tick-marks are to be drawn. Non-finite (infinite, NaN or NA) values are omitted. By default (when <code>NULL</code>) tickmark locations are computed, see ‘Details’ below.
labels	this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tick points. (Other objects are coerced by as.graphicsAnnot() .) If this is not logical, <code>at</code> should also be supplied and of the same length. If <code>labels</code> is of length zero after coercion, it has the same effect as supplying <code>TRUE</code> .
tick	a logical value specifying whether tickmarks and an axis line should be drawn.
line	the number of lines into the margin at which the axis line will be drawn, if not <code>NA</code> .
pos	the coordinate at which the axis line is to be drawn: if not <code>NA</code> this overrides the value of <code>line</code> .
outer	a logical value indicating whether the axis should be drawn in the outer plot margin, rather than the standard plot margin.
font	font for text. Defaults to <code>par("font.axis")</code> .
lty	line type for both the axis line and the tick marks.
lwd, lwd.ticks	line widths for the axis line and the tick marks. Zero or negative values will suppress the line or ticks.
col, col.ticks	colors for the axis line and the tick marks respectively. <code>col = NULL</code> means to use <code>par("fg")</code> , possibly specified inline, and <code>col.ticks = NULL</code> means to use whatever color <code>col</code> resolved to.

<code>hadj</code>	adjustment (see <code>par("adj")</code>) for all labels <i>parallel</i> ('horizontal') to the reading direction. If this is not a finite value, the default is used (centring for strings parallel to the axis, justification of the end nearest the axis otherwise).
<code>padj</code>	adjustment for each tick label <i>perpendicular</i> to the reading direction. For labels parallel to the axes, <code>padj = 0</code> means left or bottom alignment, and <code>padj = 1</code> means right or top alignment (relative to the line). This can be a vector given a value for each string, and will be recycled as necessary. If <code>padj</code> is not a finite value (the default), the value of <code>par("las")</code> determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.
<code>gap.axis</code>	an optional (typically non-negative) numeric factor to be multiplied with the size of an 'm' to determine the minimal gap between labels that are drawn, see 'Details'. The default, <code>NA</code> , corresponds to 1 for tick labels drawn <i>parallel</i> to the axis and 0.25 otherwise, i.e., the default is equivalent to <pre>perpendicular <- function(side, las) { is.x <- (side %% 2 == 1) # is horizontal x-axis (is.x && (las %in% 2:3)) (!is.x && (las %in% 1:2)) } gap.axis <- if(perpendicular(side, las)) 0.25 else 1</pre> <code>gap.axis</code> may typically be relevant when <code>at = ..</code> tick-mark positions are specified explicitly.
<code>...</code>	other graphical parameters may also be passed as arguments to this function, particularly, <code>cex.axis</code> , <code>col.axis</code> and <code>font.axis</code> for axis annotation, i.e. tick labels, <code>mgp</code> and <code>xaxp</code> or <code>yaxp</code> for positioning, <code>tick</code> or <code>ttl</code> for tick mark length and direction, <code>las</code> for vertical/horizontal label orientation, or <code>fg</code> instead of <code>col</code> , and <code>xpd</code> for clipping. See par on these. Parameters <code>xaxt</code> (sides 1 and 3) and <code>yaxt</code> (sides 2 and 4) control if the axis is plotted at all. Note that <code>lab</code> will partial match to argument <code>labels</code> unless the latter is also supplied. (Since the default axes have already been set up by <code>plot.window</code> , <code>lab</code> will not be acted on by <code>axis</code> .)

Details

The axis line is drawn from the lowest to the highest value of `at`, but will be clipped at the plot region. By default, only ticks which are drawn from points within the plot region (up to a tolerance for rounding error) are plotted, but the ticks and their labels may well extend outside the plot region. Use `xpd = TRUE` or `xpd = NA` to allow axes to extend further.

When `at = NULL`, pretty tick mark locations are computed internally (the same way `axTicks(side)` would) from `par("xaxp")` or `"yaxp"` and `par("xlog")` (or `"ylog"`). Note that these locations may change if an on-screen plot is resized (for example, if the `plot` argument `asp` (see `plot.window`) is set.)

If `labels` is not specified, the numeric values supplied or calculated for `at` are converted to character strings as if they were a numeric vector printed by `print.default(digits = 7)`.

The code tries hard not to draw overlapping tick labels, and so will omit labels where they would abut or overlap previously drawn labels. This can result in, for example, every other tick being labelled. The ticks are drawn left to right or bottom to top, and space at least the size of an 'm', multiplied by `gap.axis`, is left between labels. In previous R versions, this applied only for labels

written *parallel* to the axis direction, hence not for e.g., `las = 2`. Using `gap.axis = -1` restores that (buggy) previous behaviour (in the perpendicular case).

If either `line` or `pos` is set, they (rather than `par("mgp")[3]`) determine the position of the axis line and tick marks, and the tick labels are placed `par("mgp")[2]` further lines into (or towards for `pos`) the margin.

Several of the graphics parameters affect the way axes are drawn. The vertical (for sides 1 and 3) positions of the axis and the tick labels are controlled by `mgp[2:3]` and `mex`, the size and direction of the ticks is controlled by `tck` and `tcl` and the appearance of the tick labels by `cex.axis`, `col.axis` and `font.axis` with orientation controlled by `las` (but not `srt`, unlike `S` which uses `srt` if `at` is supplied and `las` if it is not). Note that `adj` is not supported and labels are always centered. See [par](#) for details.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also

[Axis](#) for a generic interface.

[axTicks](#) returns the axis tick locations corresponding to `at = NULL`; [pretty](#) is more flexible for computing pretty tick coordinates and does *not* depend on (nor adapt to) the coordinate system in use.

Several graphics parameters affecting the appearance are documented in [par](#).

Examples

```
require(stats) # for rnorm
plot(1:4, rnorm(4), axes = FALSE)
axis(1, 1:4, LETTERS[1:4])
axis(2)
box() #- to make it look "as usual"

plot(1:7, rnorm(7), main = "axis() examples",
     type = "s", xaxt = "n", frame.plot = FALSE, col = "red")
axis(1, 1:7, LETTERS[1:7], col.axis = "blue")
# unusual options:
axis(4, col = "violet", col.axis = "dark violet", lwd = 2)
axis(3, col = "gold", lty = 2, lwd = 0.5)

# one way to have a custom x axis
plot(1:10, xaxt = "n")
axis(1, xaxp = c(2, 9, 7))

## Changing default gap between labels:
plot(0:100, type="n", axes=FALSE, ann=FALSE)
```

```

title(quote("axis(1, ..., gap.axis = f)," ~~ f >= 0))
axis(2, at = 5*(0:20), las = 1, gap.axis = 1/4)
gaps <- c(4, 2, 1, 1/2, 1/4, 0.1, 0)
chG <- paste0(ifelse(gaps == 1, "default: ", ""),
              "gap.axis=", formatC(gaps))
jj <- seq_along(gaps)
linG <- -2.5*(jj-1)
for(j in jj) {
  isD <- gaps[j] == 1 # is default
  axis (1, at=5*(0:20), gap.axis = gaps[j], padj=-1, line = linG[j],
        col.axis = if(isD) "forest green" else 1, font.axis= 1+isD)
}
mtext(chG, side=1, padj=-1, line = linG -1/2, cex=3/4,
      col = ifelse(gaps == 1, "forest green", "blue3"))
## now shrink the window (in x- and y-direction) and observe the axis labels drawn

```

axis.POSIXct

*Date and Date-time Plotting Functions***Description**

Add a date/time axis to the current plot of an object of class "POSIXt" or "Date", respectively.

Usage

```

axis.POSIXct(side, x, at, format, labels = TRUE, ...)
axis.Date(side, x, at, format, labels = TRUE, ...)

```

Arguments

side	see axis .
x, at	optional date-time or Date objects, or other types of objects that can be converted appropriately.
format	an optional character string specifying the label format, see strftime .
labels	either a logical value specifying whether annotations are to be made at the tick-marks, or a character vector of labels to be placed at the tick points specified by at.
...	further arguments to be passed from or to other methods, typically graphical parameters .

Details

If at is unspecified, axis.POSIXct and axis.Date work quite hard (from R 4.3.0 via [pretty](#) for [date-time](#) classes) to choose suitable time units (years, months, days, hours, minutes, or seconds) and a sensible label format based on the axis range. `par("lab")` controls the approximate number of intervals.

If at is supplied it specifies the locations of the ticks and labels. If the label format is unspecified, a good guess is made by looking at the granularity of at. Printing of tick labels can be suppressed with labels = FALSE.

The date-times for a "POSIXct" input are interpreted in the time zone give by the "tzzone" attribute if there is one, otherwise the current time zone.

The way the date-times are rendered (especially month names) is controlled by the locale setting of category "LC_TIME" (see [Sys.setlocale](#)).

Value

The locations on the axis scale at which tick marks were drawn.

See Also

[DateTimeClasses](#), [Dates](#) for details of the classes.

[Axis](#).

Examples

```
with(beaver1, {
  opar <- par(mfrow = c(3,1))

axis.POSIXct(3, CET, at="2022-10-01 12:10", col.axis = "violet")

```

axTicks

Compute Axis Tickmark Locations

Description

Compute pretty tickmark locations, the same way as **R** does internally. This is only non-trivial when **log** coordinates are active. By default, gives the `at` values which `axis(side)` would use.

Usage

```
axTicks(side, axp = NULL, usr = NULL, log = NULL, nintLog = NULL)
```

Arguments

<code>side</code>	integer in 1:4, as for <code>axis</code> .
<code>axp</code>	numeric vector of length three, defaulting to <code>par("xaxp")</code> or <code>par("yaxp")</code> depending on the <code>side</code> argument (<code>par("xaxp")</code> if <code>side</code> is 1 or 3, <code>par("yaxp")</code> if <code>side</code> is 2 or 4).

usr	numeric vector of length two giving user coordinate limits, defaulting to the relevant portion of <code>par("usr")</code> (<code>par("usr")[1:2]</code> or <code>par("usr")[3:4]</code> for side in (1,3) or (2,4) respectively).
log	logical indicating if log coordinates are active; defaults to <code>par("xlog")</code> or <code>par("ylog")</code> depending on side.
nintLog	(only used when <code>log</code> is true): approximate (lower bound for the) number of tick intervals; defaults to <code>par("lab")[j]</code> where <code>j</code> is 1 or 2 depending on side. Set this to <code>Inf</code> if you want the same behavior as in earlier R versions (than 2.14.x).

Details

The `axp`, `usr`, and `log` arguments must be consistent as their default values (the `par(. .)` results) are. If you specify all three (as non-NULL), the graphics environment is not used at all. Note that the meaning of `axp` differs significantly when `log` is TRUE; see the documentation on `par(xaxp = .)`.

`axTicks()` may be seen as an R implementation of the C function `CreateAtVector()` in `'.../src/main/plot.c'` which is called by `axis(side, *)` when no argument at is specified or directly by `axisTicks()` (in package **grDevices**).

The delicate case, `log = TRUE`, now makes use of `axisTicks` unless `nintLog = Inf` which exists for back compatibility.

Value

numeric vector of coordinate values at which axis tickmarks can be drawn. By default, when only the first argument is specified, these values should be identical to those that `axis(side)` would use or has used. Note that the values are decreasing when `usr` is ("reverse axis" case).

See Also

`axis`, `par`. `pretty` uses the same algorithm (but independently of the graphics environment) and has more options. However it is not available for `log = TRUE`.

`axisTicks()` (package **grDevices**).

Examples

```
plot(1:7, 10*21:27)
axTicks(1)
axTicks(2)
stopifnot(identical(axTicks(1), axTicks(3)),
           identical(axTicks(2), axTicks(4)))

## Show how axTicks() and axis() correspond :
op <- par(mfrow = c(3, 1))
for(x in 9999 * c(1, 2, 8)) {
  plot(x, 9, log = "x")
  cat(formatC(par("xaxp"), width = 5), "; ", T <- axTicks(1), "\n")
  rug(T, col = adjustcolor("red", 0.5), lwd = 4)
}
par(op)

x <- 9.9*10^(-3:10)
plot(x, 1:14, log = "x")
axTicks(1) # now length 7
```

```
axTicks(1, nintLog = Inf) # rather too many

## An example using axTicks() without reference to an existing plot
## (copying R's internal procedures for setting axis ranges etc.),
## You do need to supply _all_ of axp, usr, log, nintLog
## standard logarithmic y axis labels
ylims <- c(0.2, 88)
get_axp <- function(x) 10^c(ceiling(x[1]), floor(x[2]))
## mimic par("yaxis") == "i"
usr.i <- log10(ylims)
(aT.i <- axTicks(side = 2, usr = usr.i,
                 axp = c(get_axp(usr.i), n = 3), log = TRUE, nintLog = 5))
## mimic (default) par("yaxis") == "r"
usr.r <- extendrange(r = log10(ylims), f = 0.04)
(aT.r <- axTicks(side = 2, usr = usr.r,
                 axp = c(get_axp(usr.r), 3), log = TRUE, nintLog = 5))

## Prove that we got it right :
plot(0:1, ylims, log = "y", yaxs = "i")
stopifnot(all.equal(aT.i, axTicks(side = 2)))

plot(0:1, ylims, log = "y", yaxs = "r")
stopifnot(all.equal(aT.r, axTicks(side = 2)))
```

barplot

Bar Plots

Description

Creates a bar plot with vertical or horizontal bars, stacked or side by side.

Usage

```
barplot(height, ...)
```

Default S3 method:

```
barplot(height, width = 1, space = NULL,
        names.arg = NULL, legend.text = NULL, beside = FALSE,
        horiz = FALSE, density = NULL, angle = 45,
        col = NULL, border = par("fg"),
        main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
        xlim = NULL, ylim = NULL, xpd = TRUE, log = "",
        axes = TRUE, axisnames = TRUE,
        cex.axis = par("cex.axis"), cex.names = par("cex.axis"),
        inside = TRUE, plot = TRUE, axis.lty = 0, offset = 0,
        add = FALSE, ann = !add && par("ann"), args.legend = NULL,
        orderH = c("none", "incr", "decr"),
        panel.first = NULL, panel.last = NULL,
        ...)
```

S3 method for class 'formula'

```
barplot(formula, data, subset, na.action,
        horiz = FALSE, xlab = NULL, ylab = NULL, ...)
```

Arguments

<code>height</code>	either a vector or matrix of values describing the bars which make up the plot. If <code>height</code> is a vector, the plot consists of a sequence of rectangular bars with heights given by the values in the vector. If <code>height</code> is a matrix and <code>beside</code> is <code>FALSE</code> then each bar of the plot corresponds to a column of <code>height</code> , with the values in the column giving the heights of stacked sub-bars making up the bar. If <code>height</code> is a matrix and <code>beside</code> is <code>TRUE</code> , then the values in each column are juxtaposed rather than stacked.
<code>width</code>	optional vector of bar widths. Re-cycled to length the number of bars drawn. Specifying a single value will have no visible effect unless <code>xlim</code> is specified.
<code>space</code>	the amount of space (as a fraction of the average bar width) left before each bar. May be given as a single number or one number per bar. If <code>height</code> is a matrix and <code>beside</code> is <code>TRUE</code> , <code>space</code> may be specified by two numbers, where the first is the space between bars in the same group, and the second the space between the groups. If not given explicitly, it defaults to <code>c(0, 1)</code> if <code>height</code> is a matrix and <code>beside</code> is <code>TRUE</code> , and to 0.2 otherwise.
<code>names.arg</code>	a vector of names to be plotted below each bar or group of bars. If this argument is omitted, then the names are taken from the <code>names</code> attribute of <code>height</code> if this is a vector, or the column names if it is a matrix.
<code>legend.text</code>	a vector of text used to construct a legend for the plot, or a logical indicating whether a legend should be included. This is only useful when <code>height</code> is a matrix. In that case given legend labels should correspond to the rows of <code>height</code> ; if <code>legend.text</code> is true, the row names of <code>height</code> will be used as labels if they are non-null.
<code>beside</code>	a logical value. If <code>FALSE</code> , the columns of <code>height</code> are portrayed as stacked bars, and if <code>TRUE</code> the columns are portrayed as juxtaposed bars.
<code>horiz</code>	a logical value. If <code>FALSE</code> , the bars are drawn vertically with the first bar to the left. If <code>TRUE</code> , the bars are drawn horizontally with the first at the bottom.
<code>density</code>	a vector giving the density of shading lines, in lines per inch, for the bars or bar components. The default value of <code>NULL</code> means that no shading lines are drawn. Non-positive values of <code>density</code> also inhibit the drawing of shading lines.
<code>angle</code>	the slope of shading lines, given as an angle in degrees (counter-clockwise), for the bars or bar components.
<code>col</code>	a vector of colors for the bars or bar components. By default, "grey" is used if <code>height</code> is a vector, and a gamma-corrected grey palette if <code>height</code> is a matrix; see grey.colors .
<code>border</code>	the color to be used for the border of the bars. Use <code>border = NA</code> to omit borders. If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
<code>main, sub</code>	main title and subtitle for the plot.
<code>xlab</code>	a label for the x axis.
<code>ylab</code>	a label for the y axis.
<code>xlim</code>	limits for the x axis.
<code>ylim</code>	limits for the y axis.
<code>xpd</code>	logical. Should bars be allowed to go outside region?
<code>log</code>	string specifying if axis scales should be logarithmic; see plot.default .
<code>axes</code>	logical. If <code>TRUE</code> , a vertical (or horizontal, if <code>horiz</code> is true) axis is drawn.

<code>axisnames</code>	logical. If TRUE, and if there are <code>names.arg</code> (see above), the other axis is drawn (with <code>lty = 0</code>) and labeled.
<code>cex.axis</code>	expansion factor for numeric axis labels (see <code>par('cex')</code>).
<code>cex.names</code>	expansion factor for axis names (bar labels).
<code>inside</code>	logical. If TRUE, the lines which divide adjacent (non-stacked!) bars will be drawn. Only applies when <code>space = 0</code> (which it partly is when <code>beside = TRUE</code>).
<code>plot</code>	logical. If FALSE, nothing is plotted.
<code>axis.lty</code>	the graphics parameter <code>lty</code> (see <code>par('lty')</code>) applied to the axis and tick marks of the categorical (default horizontal) axis. Note that by default the axis is suppressed.
<code>offset</code>	a vector indicating how much the bars should be shifted relative to the x axis.
<code>add</code>	logical specifying if bars should be added to an already existing plot; defaults to FALSE.
<code>ann</code>	logical specifying if the default annotation (<code>main</code> , <code>sub</code> , <code>xlab</code> , <code>ylab</code>) should appear on the plot, see <code>title</code> .
<code>args.legend</code>	list of additional arguments to pass to <code>legend()</code> ; names of the list are used as argument names. Only used if <code>legend.text</code> is supplied.
<code>orderH</code>	a string, one of "none", "incr", "decr" (possibly abbreviated). When (as per default) <code>beside</code> is false, and stacked bars are drawn and <code>orderH</code> is not "none", it indicates how the stacks should be ordered, each via <code>order(height[...], decreasing = <L>)</code> , where <code><L></code> is TRUE or FALSE when <code>orderH</code> is "decr" or "incr", respectively.
<code>formula</code>	a formula where the y variables are numeric data to plot against the categorical x variables. The formula can have one of three forms: $y \sim x$ $y \sim x_1 + x_2$ $\text{cbind}(y_1, y_2) \sim x$ (see the examples).
<code>data</code>	a data frame (or list) from which the variables in formula should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.
<code>panel.first</code>	an 'expression' to be evaluated after the plot axes are set up but before any plotting takes place. This can be useful for drawing background grids. Note that this works by lazy evaluation: passing this argument from other functions may well not work since it may be evaluated too early.
<code>panel.last</code>	an expression to be evaluated after plotting has taken place but before the axes and title are added. See the comments about <code>panel.first</code> .
<code>...</code>	arguments to be passed to/from other methods. For the default method these can include further arguments (such as <code>axes</code> , <code>asp</code> and <code>main</code>) and graphical parameters (see <code>par</code>) which are passed to <code>plot.window()</code> , <code>title()</code> and <code>axis</code> .

Value

A numeric vector (or matrix, when `beside = TRUE`), say `mp`, giving the coordinates of *all* the bar midpoints drawn, useful for adding to the graph.

If `beside` is true, use `colMeans(mp)` for the midpoints of each *group* of bars, see example.

Author(s)

R Core, with a contribution by Arni Magnusson, and `orderH` by François Rebaudo, see also Fig.~3 in [doi:10.1111/eea.12693](https://doi.org/10.1111/eea.12693).

barplot(mydat, col=myCol, orderH = "incr", main= "orderH = 'incr'")

```

box

Draw a Box around a Plot

Description

This function draws a box around the current plot in the given color and line type. The `bty` parameter determines the type of box drawn. See [par](#) for details.

Usage

```
box(which = "plot", lty = "solid", ...)
```

Arguments

<code>which</code>	character, one of "plot", "figure", "inner" and "outer".
<code>lty</code>	line type of the box.
<code>...</code>	further graphical parameters , such as <code>bty</code> , <code>col</code> , or <code>lwd</code> , see par . Note that <code>xpd</code> is not accepted as clipping is always to the device region.

Details

The choice of colour is complicated. If `col` was supplied and is not NA, it is used. Otherwise, if `fg` was supplied and is not NA, it is used. The final default is `par("col")`.

References

Becker RA, Chambers JM, Wilks AR (1988). *The New S Language*. Chapman and Hall/CRC, London. ISBN 053409192X.

See Also

[rect](#) for drawing of arbitrary rectangles.

Examples

```
plot(1:7, abs(stats::rnorm(7)), type = "h", axes = FALSE)
axis(1, at = 1:7, labels = letters[1:7])
box(lty = '1373', col = 'red')
```

boxplot

Box Plots

Description

Produce box-and-whisker plot(s) of the given (grouped) values.

Usage

```

boxplot(x, ...)

## S3 method for class 'formula'
boxplot(formula, data = NULL, ..., subset, na.action = NULL,
        xlab = mklab(y_var = horizontal),
        ylab = mklab(y_var != horizontal),
        add = FALSE, ann = !add, horizontal = FALSE,
        drop = FALSE, sep = ".", lex.order = FALSE)

## Default S3 method:
boxplot(x, ..., range = 1.5, width = NULL, varwidth = FALSE,
        notch = FALSE, outline = TRUE, names, plot = TRUE,
        border = par("fg"), col = "lightgray", log = "",
        pars = list(boxwex = 0.8, staplewex = 0.5, outwex = 0.5),
        ann = !add, horizontal = FALSE, add = FALSE, at = NULL)

```

Arguments

<code>formula</code>	a formula, such as <code>y ~ grp</code> , where <code>y</code> is a numeric vector of data values to be split into groups according to the grouping variable <code>grp</code> (usually a factor). Note that <code>~ g1 + g2</code> is equivalent to <code>g1:g2</code> .
<code>data</code>	a <code>data.frame</code> (or list) from which the variables in <code>formula</code> should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.
<code>na.action</code>	a function which indicates what should happen when the data contain <code>NA</code> s. The default is to ignore missing values in either the response or the group.
<code>xlab, ylab</code>	x- and y-axis annotation, since R 3.6.0 with a non-empty default. Can be suppressed by <code>ann=FALSE</code> .
<code>ann</code>	logical indicating if axes should be annotated (by <code>xlab</code> and <code>ylab</code>).
<code>drop, sep, lex.order</code>	passed to split.default , see there.
<code>x</code>	for specifying data from which the boxplots are to be produced. Either a numeric vector, or a single list containing such vectors. Additional unnamed arguments specify further data as separate vectors (each corresponding to a component boxplot). NA s are allowed in the data.
<code>...</code>	For the <code>formula</code> method, named arguments to be passed to the default method. For the default method, unnamed arguments are additional data vectors (unless <code>x</code> is a list when they are ignored), and named arguments are arguments and graphical parameters to be passed to bxp in addition to the ones given by argument <code>pars</code> (and override those in <code>pars</code>). Note that <code>bxp</code> may or may not make use of graphical parameters it is passed: see its documentation.
<code>range</code>	this determines how far the plot whiskers extend out from the box. If <code>range</code> is positive, the whiskers extend to the most extreme data point which is no more than <code>range</code> times the interquartile range from the box. A value of zero causes the whiskers to extend to the data extremes.
<code>width</code>	a vector giving the relative widths of the boxes making up the plot.
<code>varwidth</code>	if <code>varwidth</code> is <code>TRUE</code> , the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.

notch	if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See <code>boxplot.stats</code> for the calculations used.
outline	if outline is not true, the outliers are not drawn (as points whereas S+ uses lines).
names	group labels which will be printed under each boxplot. Can be a character vector or an expression (see <code>plotmath</code>).
boxwex	a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.
staplewex	staple line width expansion, proportional to box width.
outwex	outlier line width expansion, proportional to box width.
plot	if TRUE (the default) then a boxplot is produced. If not, the summaries which the boxplots are based on are returned.
border	an optional vector of colors for the outlines of the boxplots. The values in border are recycled if the length of border is less than the number of plots.
col	if col is non-null it is assumed to contain colors to be used to colour the bodies of the box plots. By default they are in the background colour.
log	character indicating if x or y or both coordinates should be plotted in log scale.
pars	a list of (potentially many) more graphical parameters, e.g., boxwex or outpch; these are passed to <code>bxp</code> (if plot is true); for details, see there.
horizontal	logical indicating if the boxplots should be horizontal; default FALSE means vertical boxes.
add	logical, if true add boxplot to current plot.
at	numeric vector giving the locations where the boxplots should be drawn, particularly when add = TRUE; defaults to 1 : n where n is the number of boxes.

Details

The generic function `boxplot` currently has a default method (`boxplot.default`) and a formula interface (`boxplot.formula`).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see [factor](#)).

Missing values are ignored when forming boxplots.

Value

List with the following components:

stats	a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.
n	a vector with the number of (non-NA) observations in each group.
conf	a matrix where each column contains the lower and upper extremes of the notch.
out	the values of any data points which lie beyond the extremes of the whiskers.
group	a vector of the same length as out whose elements indicate to which group the outlier belongs.
names	a vector of names for the groups.

Examples

```
## boxplot on a formula:
boxplot(count ~ spray, data = InsectSprays, col = "lightgray")
# *add* notches (somewhat funny here <--> warning "notches .. outside hinges"):
boxplot(count ~ spray, data = InsectSprays,
        notch = TRUE, add = TRUE, col = "blue")

boxplot(decrease ~ treatment, data = OrchardSprays, col = "bisque",
        log = "y")
## horizontal=TRUE, switching y <--> x :
boxplot(decrease ~ treatment, data = OrchardSprays, col = "bisque",
        log = "x", horizontal=TRUE)

rb <- boxplot(decrease ~ treatment, data = OrchardSprays, col = "bisque")
title("Comparing boxplot()s and non-robust mean +/- SD")
mn.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, mean)
sd.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, sd)
xi <- 0.3 + seq(rb$n)
points(xi, mn.t, col = "orange", pch = 18)
arrows(xi, mn.t - sd.t, xi, mn.t + sd.t,
       code = 3, col = "pink", angle = 75, length = .1)

## boxplot on a matrix:
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100),
            `5T` = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(mat) # directly, calling boxplot.matrix()

## boxplot on a data frame:
df. <- as.data.frame(mat)
par(las = 1) # all axis labels horizontal
boxplot(df., main = "boxplot(*, horizontal = TRUE)", horizontal = TRUE)

## Using 'at = ' and adding boxplots -- example idea by Roger Bivand :
boxplot(len ~ dose, data = ToothGrowth,
        boxwex = 0.25, at = 1:3 - 0.2,
        subset = supp == "VC", col = "yellow",
        main = "Guinea Pigs' Tooth Growth",
        xlab = "Vitamin C dose mg",
        ylab = "tooth length",
        xlim = c(0.5, 3.5), ylim = c(0, 35), yaxs = "i")
```

```

boxplot(len ~ dose, data = ToothGrowth, add = TRUE,
        boxwex = 0.25, at = 1:3 + 0.2,
        subset = supp == "OJ", col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
      fill = c("yellow", "orange"))

## With less effort (slightly different) using factor *interaction*:
boxplot(len ~ dose:supp, data = ToothGrowth,
        boxwex = 0.5, col = c("orange", "yellow"),
        main = "Guinea Pigs' Tooth Growth",
        xlab = "Vitamin C dose mg", ylab = "tooth length",
        sep = ":", lex.order = TRUE, ylim = c(0, 35), yaxs = "i")

## more examples in help(bxp)

```

boxplot.matrix	<i>Draw a Boxplot for each Column (Row) of a Matrix</i>
----------------	---

Description

Interpreting the columns (or rows) of a matrix as different groups, draw a boxplot for each.

Usage

```

## S3 method for class 'matrix'
boxplot(x, use.cols = TRUE, ...)

```

Arguments

x	a numeric matrix.
use.cols	logical indicating if columns (by default) or rows (use.cols = FALSE) should be plotted.
...	Further arguments to <code>boxplot</code> .

Value

A list as for `boxplot`.

Author(s)

Martin Maechler, 1995, for S+, then R package **sfsmisc**.

See Also

`boxplot.default` which already works nowadays with `data.frames`; `boxplot.formula`, `plot.factor` which work with (the more general concept) of a grouping factor.

Examples

```

## Very similar to the example in ?boxplot
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100),
            T5 = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(mat, main = "boxplot.matrix(..., main = ...)",
        notch = TRUE, col = 1:4)

```

bxp

*Draw Box Plots from Summaries***Description**

bxp draws box plots based on the given summaries in `z`. It is usually called from within `boxplot`, but can be invoked directly.

Usage

```
bxp(z, notch = FALSE, width = NULL, varwidth = FALSE,
    outline = TRUE, notch.frac = 0.5, log = "",
    border = par("fg"), pars = NULL, frame.plot = axes,
    horizontal = FALSE, ann = TRUE,
    add = FALSE, at = NULL, show.names = NULL,
    panel.first = NULL, panel.last = NULL, ...)
```

Arguments

<code>z</code>	a list containing data summaries to be used in constructing the plots. These are usually the result of a call to <code>boxplot</code> , but can be generated in any fashion.
<code>notch</code>	if <code>notch</code> is <code>TRUE</code> , a notch is drawn in each side of the boxes. If the notches of two plots do not overlap then the medians are significantly different at the 5 percent level.
<code>width</code>	a vector giving the relative widths of the boxes making up the plot.
<code>varwidth</code>	if <code>varwidth</code> is <code>TRUE</code> , the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
<code>outline</code>	if <code>outline</code> is not true, the outliers are not drawn.
<code>notch.frac</code>	numeric in (0,1). When <code>notch = TRUE</code> , the fraction of the box width that the notches should use.
<code>border</code>	character or numeric (vector), the color of the box borders. Is recycled for multiple boxes. Is used as default for the <code>boxcol</code> , <code>medcol</code> , <code>whiskcol</code> , <code>staplecol</code> , and <code>outcol</code> options (see below).
<code>log</code>	character, indicating if any axis should be drawn in logarithmic scale, as in <code>plot.default</code> .
<code>frame.plot</code>	logical, indicating if a ‘frame’ (box) should be drawn; defaults to <code>TRUE</code> , unless <code>axes = FALSE</code> is specified.
<code>horizontal</code>	logical indicating if the boxplots should be horizontal; default <code>FALSE</code> means vertical boxes. See ‘Note’.
<code>ann</code>	a logical value indicating whether the default annotation (title and x and y axis labels) should appear on the plot.
<code>add</code>	logical, if true <i>add</i> boxplot to current plot.
<code>at</code>	numeric vector giving the locations where the boxplots should be drawn, particularly when <code>add = TRUE</code> ; defaults to <code>1:n</code> where <code>n</code> is the number of boxes.
<code>show.names</code>	Set to <code>TRUE</code> or <code>FALSE</code> to override the defaults on whether an x-axis label is printed for each group.

- `panel.first` a ‘function’ (not an ‘expression’!) that is called without arguments after the plot axes are set up but before any plotting takes place. This can be useful for drawing background grids.
- `panel.last` a ‘function’ (not an ‘expression’!) that is called after plotting has taken place but before the axes and title are added.
- `pars, ...` [graphical parameters](#) (etc) can be passed as arguments to this function, either as a list (`pars`) or normally(`...`), see the following. (Those in `...` take precedence over those in `pars`.)
- `xaxt`, `yaxt`, `las`, `cex.axis`, `gap.axis`, and `col.axis` are passed to [axis](#), and `main`, `cex.main`, `col.main`, `sub`, `cex.sub`, `col.sub`, `xlab`, `ylab`, `cex.lab`, and `col.lab` are passed to [title](#).
- In addition, `axes` is accepted (see [plot.window](#)), with default `TRUE`.
- The following arguments (or `pars` components) allow further customization of the boxplot graphics. Their defaults are typically determined from the non-prefixed version (e.g., `boxlty` from `lty`), either from the specified argument or `pars` component or the corresponding `par` one.
- boxwex:** a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower. The default depends on `at` and typically is 0.8.
- staplewex, outwex:** staple and outlier line width expansion, proportional to box width; both default to 0.5.
- boxlty, boxlwd, boxcol, boxfill:** box outline type, width, color, and fill color (which currently defaults to `col` and will in future default to `par("bg")`).
- medlty, medlwd, medpch, medcex, medcol, medbg:** median line type, line width, point character, point size expansion, color, and background color. The default `medpch = NA` suppresses the point, and `medlty = "blank"` does so for the line. Note that `medlwd` defaults to $3 \times$ the default `lwd`.
- whisklty, whisklwd, whiskcol:** whisker line type (default: `"dashed"`), width, and color.
- staplelty, staplelwd, staplecol:** staple (= end of whisker) line type, width, and color.
- outlty, outlwd, outpch, outcex, outcol, outbg:** outlier line type, line width, point character, point size expansion, color, and background color. The default `outlty = "blank"` suppresses the lines and `outpch = NA` suppresses points.

Value

An invisible vector, actually identical to the `at` argument, with the coordinates ("x" if horizontal is false, "y" otherwise) of box centers, useful for adding to the plot.

Note

When `add = FALSE`, `xlim` now defaults to `xlim = range(at, *) + c(-0.5, 0.5)`. It will usually be a good idea to specify `xlim` if the "x" axis has a log scale or `width` is far from uniform.

If `horizontal = TRUE`, the "y" axis is the horizontal axis and the "x" axis is the vertical axis. Graphical parameters `xlim/ylim` and `xaxs/yaxs` are reversed in this case. Other axis related parameters treat the vertical axis as "y" and the horizontal axis as "x".

```

cdplot

Conditional Density Plots

Description

Computes and plots conditional densities describing how the conditional distribution of a categorical variable y changes over a numerical variable x .

Usage

```

cdplot(x, ...)

## Default S3 method:
cdplot(x, y,
       plot = TRUE, tol.ylab = 0.05, ylevels = NULL,
       bw = "nrd0", n = 512, from = NULL, to = NULL,
       col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
       yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), weights = NULL, ...)

## S3 method for class 'formula'
cdplot(formula, data = list(),
       plot = TRUE, tol.ylab = 0.05, ylevels = NULL,
       bw = "nrd0", n = 512, from = NULL, to = NULL,
       col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
       yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...,
       subset = NULL, weights = NULL)

```

Arguments

<code>x</code>	an object, the default method expects a single numerical variable (or an object coercible to this).
<code>y</code>	a "factor" interpreted to be the dependent variable
<code>formula</code>	a "formula" of type $y \sim x$ with a single dependent "factor" and a single numerical explanatory variable.
<code>data</code>	an optional data frame.
<code>plot</code>	logical. Should the computed conditional densities be plotted?
<code>tol.ylab</code>	convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.
<code>ylevels</code>	a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.
<code>bw, n, from, to, ...</code>	arguments passed to density
<code>col</code>	a vector of fill colors of the same length as <code>levels(y)</code> . The default is to call gray.colors .

<code>border</code>	border color of shaded polygons.
<code>main, xlab, ylab</code>	character strings for annotation
<code>yaxlabels</code>	character vector for annotation of y axis, defaults to <code>levels(y)</code> .
<code>xlim, ylim</code>	the range of x and y values with sensible defaults.
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.
<code>weights</code>	numeric. A vector of frequency weights for each observation in the data. If NULL all weights are implicitly assumed to be 1.

Details

`cdplot` computes the conditional densities of x given the levels of y weighted by the marginal distribution of y . The densities are derived cumulatively over the levels of y .

This visualization technique is similar to spinograms (see [spineplot](#)) and plots $P(y|x)$ against x . The conditional probabilities are not derived by discretization (as in the spinogram), but using a smoothing approach via [density](#).

Note, that the estimates of the conditional densities are more reliable for high-density regions of x . Conversely, they are less reliable in regions with only few x observations.

Value

The conditional density functions (cumulative over the levels of y) are returned invisibly.

     xlab = "Temperature", ylab = "Conditional failure probability")
lines(53:81, 1 - cdens[[1]](53:81), col = 2)
```

clip

*Set Clipping Region***Description**

Set clipping region in user coordinates.

Usage

```
clip(x1, x2, y1, y2)
```

Arguments

`x1, x2, y1, y2` user coordinates of clipping rectangle

Details

How the clipping rectangle is set depends on the setting of `par("xpd")`: this function changes the current setting until the next high-level plotting command resets it.

Clipping of lines, rectangles and polygons is done in the graphics engine, but clipping of text is if possible done in the device, so the effect of clipping text is device-dependent (and may result in text not wholly within the clipping region being omitted entirely).

Exactly when the clipping region will be reset can be hard to predict. `plot.new` always resets it. Functions such as `lines` and `text` only reset it if `par("xpd")` has been changed. However, functions such as `box`, `mtext`, `title` and `plot.dendrogram` can manipulate the `xpd` setting.

Value

Invisible NULL.

See Also

`par`

Examples

```
x <- rnorm(1000)
hist(x, xlim = c(-4,4))
usr <- par("usr")
clip(usr[1], -2, usr[3], usr[4])
hist(x, col = 'red', add = TRUE)
clip(2, usr[2], usr[3], usr[4])
hist(x, col = 'blue', add = TRUE)
do.call("clip", as.list(usr)) # reset to plot region
```

contour

*Display Contours***Description**

Create a contour plot, or add contour lines to an existing plot.

Usage

```
contour(x, ...)

## Default S3 method:
contour(x = seq(0, 1, length.out = nrow(z)),
        y = seq(0, 1, length.out = ncol(z)),
        z,
        nlevels = 10, levels = pretty(zlim, nlevels),
        labels = NULL,
        xlim = range(x, finite = TRUE),
        ylim = range(y, finite = TRUE),
        zlim = range(z, finite = TRUE),
        labcex = 0.6, drawlabels = TRUE, method = "flattest",
        vfont, axes = TRUE, frame.plot = axes,
        col = par("fg"), lty = par("lty"), lwd = par("lwd"),
        add = FALSE, ...)
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a list, its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively. If the list has component <code>z</code> this is used for <code>z</code> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>nlevels</code>	number of contour levels desired iff <code>levels</code> is not supplied.
<code>levels</code>	numeric vector of levels at which to draw contour lines.
<code>labels</code>	a vector giving the labels for the contour lines. If <code>NULL</code> then the levels are used as labels, otherwise this is coerced by as.character .
<code>labcex</code>	<code>cex</code> for contour labelling. This is an absolute size, not a multiple of <code>par("cex")</code> .
<code>drawlabels</code>	logical. Contours are labelled if <code>TRUE</code> .
<code>method</code>	character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the 'Details' section.
<code>vfont</code>	if <code>NULL</code> , the current font family and face are used for the contour labels. If a character vector of length 2 then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a font index (see text for more information). The default is <code>NULL</code> on graphics devices with high-quality rotation of text and <code>c("sans serif", "plain")</code> otherwise.

<code>xlim, ylim, zlim</code>	x-, y- and z-limits for the plot.
<code>axes, frame.plot</code>	logical indicating whether axes or a box should be drawn, see <code>plot.default</code> .
<code>col</code>	colour(s) for the lines drawn.
<code>lty</code>	line type(s) for the lines drawn.
<code>lwd</code>	line width(s) for the lines drawn.
<code>add</code>	logical. If TRUE, add to a current plot.
<code>...</code>	additional arguments to <code>plot.window</code> , <code>title</code> , <code>Axis</code> and <code>box</code> , typically graphical parameters such as <code>cex.axis</code> .

Details

`contour` is a generic function with only a default method in base R.

The methods for positioning the labels on contours are "simple" (draw at the edge of the plot, overlaying the contour line), "edge" (draw at the edge of the plot, embedded in the contour line, with no labels overlapping) and "flattest" (draw on the flattest section of the contour, embedded in the contour line, with no labels overlapping). The second and third may not draw a label on every contour line.

For information about vector fonts, see the help for [text](#) and [Hershey](#).

Notice that `contour` interprets the `z` matrix as a table of $f(x[i], y[j])$ values, so that the `x` axis corresponds to row number and the `y` axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional textual layout.

Vector (of length > 1) `col`, `lty`, and `lwd` are applied along `levels` and recycled, see the Examples.

Alternatively, use `contourplot` from the **lattice** package where the `formula` notation allows to use vectors `x`, `y`, and `z` of the same length.

There is limited control over the axes and frame as arguments `col`, `lwd` and `lty` refer to the contour lines (rather than being general [graphical parameters](#)). For more control, add contours to a plot, or add axes and frame to a contour plot.

par(opar)

```

Description

Convert between graphics coordinate systems.

Usage

```
grconvertX(x, from = "user", to = "user")
grconvertY(y, from = "user", to = "user")
```

Arguments

<code>x, y</code>	numeric vector of coordinates.
<code>from, to</code>	character strings giving the coordinate systems to convert between.

Details

The coordinate systems are

"user" user coordinates.

"inches" inches.

"device" the device coordinate system.

"ndc" normalized device coordinates.

"nfc" normalized figure coordinates.

"npc" normalized plot coordinates.

"nic" normalized inner region coordinates. (The 'inner region' is that inside the outer margins.)

"lines" lines of margin (based on `mex`).

"chars" lines of text (based on `cex`).

(These names can be partially matched.) For the 'normalized' coordinate systems the lower left has value 0 and the top right value 1.

Device coordinates are those in which the device works: they are usually in pixels where that makes sense and in big points (1/72 inch) otherwise (e.g., [pdf](#) and [postscript](#)).

Value

A numeric vector of the same length as the input.

Examples

```
op <- par(omd=c(0.1, 0.9, 0.1, 0.9), mfrow = c(1, 2))
plot(1:4)
for(tp in c("in", "dev", "ndc", "nfc", "npc", "nic", "lines", "chars"))
  print(grconvertX(c(1.0, 4.0), "user", tp))
par(op)
```

Description

This function produces two variants of the **conditioning** plots discussed in the reference below.

Usage

```
coplot(formula, data, given.values, panel = points, rows, columns,
       show.given = TRUE, col = par("fg"), pch = par("pch"),
       bar.bg = c(num = gray(0.8), fac = gray(0.95)),
       xlab = c(x.name, paste("Given :", a.name)),
       ylab = c(y.name, paste("Given :", b.name)),
       subscripts = FALSE,
       axlabels = function(f) abbreviate(levels(f)),
       number = 6, overlap = 0.5, xlim, ylim, ...)
co.intervals(x, number = 6, overlap = 0.5)
```

Arguments

- | | |
|--------------|---|
| formula | <p>a formula describing the form of conditioning plot. A formula of the form $y \sim x \mid a$ indicates that plots of y versus x should be produced conditional on the variable a. A formula of the form $y \sim x \mid a * b$ indicates that plots of y versus x should be produced conditional on the two variables a and b.</p> <p>All three or four variables may be either numeric or factors. When x or y are factors, the result is almost as if <code>as.numeric()</code> was applied, whereas for factor a or b, the conditioning (and its graphics if <code>show.given</code> is true) are adapted.</p> |
| data | a data frame containing values for any variables in the formula. By default the environment where <code>coplot</code> was called from is used. |
| given.values | <p>a value or list of two values which determine how the conditioning on a and b is to take place.</p> <p>When there is no b (i.e., conditioning only on a), usually this is a matrix with two columns each row of which gives an interval, to be conditioned on, but is can also be a single vector of numbers or a set of factor levels (if the variable being conditioned on is a factor). In this case (no b), the result of <code>co.intervals</code> can be used directly as <code>given.values</code> argument.</p> |
| panel | a <code>function(x, y, col, pch, ...)</code> which gives the action to be carried out in each panel of the display. The default is <code>points</code> . |
| rows | the panels of the plot are laid out in a <code>rows by columns</code> array. <code>rows</code> gives the number of rows in the array. |
| columns | the number of columns in the panel layout array. |
| show.given | logical (possibly of length 2 for 2 conditioning variables): should conditioning plots be shown for the corresponding conditioning variables (default TRUE). |
| col | a vector of colors to be used to plot the points. If too short, the values are recycled. |
| pch | a vector of plotting symbols or characters. If too short, the values are recycled. |

<code>bar.bg</code>	a named vector with components "num" and "fac" giving the background colors for the (shingle) bars, for numeric and factor conditioning variables respectively.
<code>xlab</code>	character; labels to use for the x axis and the first conditioning variable. If only one label is given, it is used for the x axis and the default label is used for the conditioning variable.
<code>ylab</code>	character; labels to use for the y axis and any second conditioning variable.
<code>subscripts</code>	logical: if true the panel function is given an additional (third) argument <code>subscripts</code> giving the subscripts of the data passed to that panel.
<code>axlabels</code>	function for creating axis (tick) labels when x or y are factors.
<code>number</code>	integer; the number of conditioning intervals, for a and b, possibly of length 2. It is only used if the corresponding conditioning variable is not a factor .
<code>overlap</code>	numeric < 1; the fraction of overlap of the conditioning variables, possibly of length 2 for x and y direction. When <code>overlap < 0</code> , there will be <i>gaps</i> between the data slices.
<code>xlim</code>	the range for the x axis.
<code>ylim</code>	the range for the y axis.
<code>...</code>	additional arguments to the panel function.
<code>x</code>	a numeric vector.

Details

In the case of a single conditioning variable `a`, when both `rows` and `columns` are unspecified, a ‘close to square’ layout is chosen with `columns >= rows`.

In the case of multiple `rows`, the *order* of the panel plots is from the bottom and from the left (corresponding to increasing `a`, typically).

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus `plot` and `boxplot` are not panel functions.

The rendering of arguments `xlab` and `ylab` is not controlled by `par` arguments `cex.lab` and `font.lab` even though they are plotted by `mtext` rather than `title`.

Value

`co.intervals(., number, .)` returns a $(\text{number} \times 2)$ [matrix](#), say `ci`, where `ci[k, ]` is the [range](#) of `x` values for the `k`-th interval.

Examples

```
## Tonga Trench Earthquakes
coplot(lat ~ long | depth, data = quakes)
given.depth <- co.intervals(quakes$depth, number = 4, overlap = .1)
coplot(lat ~ long | depth, data = quakes, given.values = given.depth, rows = 1)

## Conditioning on 2 variables:
ll.dm <- lat ~ long | depth * mag
coplot(ll.dm, data = quakes)
coplot(ll.dm, data = quakes, number = c(4, 7), show.given = c(TRUE, FALSE))
coplot(ll.dm, data = quakes, number = c(3, 7),
       overlap = c(-.5, .1)) # negative overlap DROPS values

## given two factors
Index <- seq_len(nrow(warpbreaks)) # to get nicer default labels
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       show.given = 0:1)
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       col = "red", bg = "pink", pch = 21,
       bar.bg = c(fac = "light blue"))

## Example with empty panels:
with(data.frame(state.x77), {
  coplot(Life.Exp ~ Income | Illiteracy * state.region, number = 3,
        panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...))
  ## y ~ factor -- not really sensible, but 'show off':
  coplot(Life.Exp ~ state.region | Income * state.division,
        panel = panel.smooth)
})
```

curve

Draw Function Plots

Description

Draws a curve corresponding to a function over the interval `[from, to]`. `curve` can plot also an expression in the variable `xname`, default `'x'`.

Usage

```
curve(expr, from = NULL, to = NULL, n = 101, add = FALSE,
      type = "l", xname = "x", xlab = xname, ylab = NULL,
      log = NULL, xlim = NULL, ...)

## S3 method for class 'function'
plot(x, y = 0, to = 1, from = y, xlim = NULL, ylab = NULL, ...)
```

Arguments

<code>expr</code>	The name of a function, or a call or an expression written as a function of <code>x</code> which will evaluate to an object of the same length as <code>x</code> .
<code>x</code>	a ‘vectorizing’ numeric R function.
<code>y</code>	alias for <code>from</code> for compatibility with <code>plot</code>

<code>from, to</code>	the range over which the function will be plotted.
<code>n</code>	integer; the number of x values at which to evaluate.
<code>add</code>	logical; if <code>TRUE</code> add to an already existing plot; if <code>NA</code> start a new plot taking the defaults for the limits and log-scaling of the x-axis from the previous plot. Taken as <code>FALSE</code> (with a warning if a different value is supplied) if no graphics device is open.
<code>xlim</code>	<code>NULL</code> or a numeric vector of length 2; if non- <code>NULL</code> it provides the defaults for <code>c(from, to)</code> and, unless <code>add = TRUE</code> , selects the x-limits of the plot – see plot.window .
<code>type</code>	plot type: see plot.default .
<code>xname</code>	character string giving the name to be used for the x axis.
<code>xlab, ylab, log, ...</code>	labels and graphical parameters can also be specified as arguments. See ‘Details’ for the interpretation of the default for <code>log</code> . For the "function" method of <code>plot</code> , <code>...</code> can include any of the other arguments of <code>curve</code> , except <code>expr</code> .

Details

The function or expression `expr` (for `curve`) or function `x` (for `plot`) is evaluated at `n` points equally spaced over the range `[from, to]`. The points determined in this way are then plotted.

If either `from` or `to` is `NULL`, it defaults to the corresponding element of `xlim` if that is not `NULL`.

What happens when neither `from/to` nor `xlim` specifies both x-limits is a complex story. For `plot(<function>)` and for `curve(add = FALSE)` the defaults are `(0, 1)`. For `curve(add = NA)` and `curve(add = TRUE)` the defaults are taken from the x-limits used for the previous plot. (This differs from versions of R prior to 2.14.0.)

The value of `log` is used both to specify the plot axes (unless `add = TRUE`) and how ‘equally spaced’ is interpreted: if the x component indicates log-scaling, the points at which the expression or function is plotted are equally spaced on log scale.

The default value of `log` is taken from the current plot when `add = TRUE`, whereas if `add = NA` the x component is taken from the existing plot (if any) and the y component defaults to linear. For `add = FALSE` the default is `" "`

This used to be a quick hack which now seems to serve a useful purpose, but can give bad results for functions which are not smooth.

For expensive-to-compute expressions, you should use smarter tools.

The way `curve` handles `expr` has caused confusion. It first looks to see if `expr` is a [name](#) (also known as a symbol), in which case it is taken to be the name of a function, and `expr` is replaced by a call to `expr` with a single argument with name given by `xname`. Otherwise it checks that `expr` is either a [call](#) or an [expression](#), and that it contains a reference to the variable given by `xname` (using `all.vars`): anything else is an error. Then `expr` is evaluated in an environment which supplies a vector of name given by `xname` of length `n`, and should evaluate to an object of length `n`. Note that this means that `curve(x, ...)` is taken as a request to plot a function named `x` (and it is used as such in the `function` method for `plot`).

The `plot` method can be called directly as `plot.function`.

Value

A list with components `x` and `y` of the points that were drawn is returned invisibly.

Warning

For historical reasons, `add` is allowed as an argument to the `"function"` method of `plot`, but its behaviour may surprise you. It is recommended to use `add` only with `curve`.

Examples

```
plot(qnorm) # default range c(0, 1) is appropriate here,
            # but end values are -/+Inf and so are omitted.
plot(qlogis, main = "The Inverse Logit : qlogis()")
abline(h = 0, v = 0:2/2, lty = 3, col = "gray")

curve(sin, -2*pi, 2*pi, xname = "t")
curve(tan, xname = "t", add = NA,
      main = "curve(tan) --> same x-scale as previous plot")

op <- par(mfrow = c(2, 2))
curve(x^3 - 3*x, -2, 2)
curve(x^2 - 2, add = TRUE, col = "violet")

## simple and advanced versions, quite similar:
plot(cos, -pi, 3*pi)
curve(cos, xlim = c(-pi, 3*pi), n = 1001, col = "blue", add = TRUE)

chippy <- function(x) sin(cos(x)*exp(-x/2))
curve(chippy, -8, 7, n = 2001)
plot (chippy, -8, -5)

for(ll in c("", "x", "y", "xy"))
  curve(log(1+x), 1, 100, log = ll, sub = paste0("log = '", ll, "'"))
par(op)
```

dotchart

Cleveland's Dot Plots

Description

Draw a Cleveland dot plot.

Usage

```
dotchart(x, labels = NULL, groups = NULL, gdata = NULL, offset = 1/8,
         ann = par("ann"), xaxt = par("xaxt"), frame.plot = TRUE, log = "",
         cex = par("cex"), pt.cex = cex,
         pch = 21, gpch = 21, bg = par("bg"),
         color = par("fg"), gcolor = par("fg"), lcolor = "gray",
         xlim = range(x[is.finite(x)]),
         main = NULL, xlab = NULL, ylab = NULL, ...)
```

Arguments

<code>x</code>	either a vector or matrix of numeric values (NAs are allowed). If <code>x</code> is a matrix the overall plot consists of juxtaposed dotplots for each row. Inputs which satisfy <code>is.numeric(x)</code> but not <code>is.vector(x) is.matrix(x)</code> are coerced by <code>as.numeric</code> , with a warning.
<code>labels</code>	a vector of labels for each point. For vectors the default is to use <code>names(x)</code> and for matrices the row labels <code>dimnames(x)[[1]]</code> .
<code>groups</code>	an optional factor indicating how the elements of <code>x</code> are grouped. If <code>x</code> is a matrix, <code>groups</code> will default to the columns of <code>x</code> .
<code>gdata</code>	data values for the groups. This is typically a summary such as the median or mean of each group.
<code>offset</code>	offset in inches of <code>ylab</code> and <code>labels</code> .
<code>ann</code>	a <code>logical</code> value indicating whether the default annotation (title and x and y axis labels) should appear on the plot.
<code>xaxt</code>	a string indicating the x-axis style; use "n" to suppress and see also <code>par("xaxt")</code> .
<code>frame.plot</code>	a logical indicating whether a box should be drawn around the plot.
<code>log</code>	a character string indicating if one or the other axis should be logarithmic, see <code>plot.default</code> .
<code>cex</code>	the character size to be used. Setting <code>cex</code> to a value smaller than one can be a useful way of avoiding label overlap. Unlike many other graphics functions, this sets the actual size, not a multiple of <code>par("cex")</code> .
<code>pt.cex</code>	the <code>cex</code> to be applied to plotting symbols. This behaves like <code>cex</code> in <code>plot()</code> .
<code>pch</code>	the plotting character or symbol to be used.
<code>gpch</code>	the plotting character or symbol to be used for group values.
<code>bg</code>	the background color of plotting characters or symbols to be used; use <code>par(bg=*)</code> to set the background color of the whole plot.
<code>color</code>	the color(s) to be used for points and labels.
<code>gcolor</code>	the single color to be used for group labels and values.
<code>lcolor</code>	the color(s) to be used for the horizontal lines.
<code>xlim</code>	horizontal range for the plot, see <code>plot.window</code> , for example.
<code>main</code>	overall title for the plot, see <code>title</code> .
<code>xlab, ylab</code>	axis annotations as in <code>title</code> .
<code>...</code>	<code>graphical parameters</code> can also be specified as arguments.

Value

This function is invoked for its side effect, which is to produce two variants of dotplots as described in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.

Examples

```
dotchart(VADeaths, main = "Death Rates in Virginia - 1940")

op <- par(xaxs = "i") # 0 -- 100%
dotchart(t(VADeaths), xlim = c(0,100), bg = "skyblue",
         main = "Death Rates in Virginia - 1940", xlab = "rate [ % ]",
         ylab = "Grouping: Age x Urbanity . Gender")
par(op)
```

filled.contour	<i>Level (Contour) Plots</i>
----------------	------------------------------

Description

This function produces a contour plot with the areas between the contours filled in solid color (Cleveland calls this a level plot). A key showing how the colors map to *z* values is shown to the right of the plot.

Usage

```
filled.contour(x = seq(0, 1, length.out = nrow(z)),
              y = seq(0, 1, length.out = ncol(z)),
              z,
              xlim = range(x, finite = TRUE),
              ylim = range(y, finite = TRUE),
              zlim = range(z, finite = TRUE),
              levels = pretty(zlim, nlevels), nlevels = 20,
              color.palette = function(n) hcl.colors(n, "YlOrRd", rev = TRUE),
              col = color.palette(length(levels) - 1),
              plot.title, plot.axes, key.title, key.axes, key.border = NULL,
              asp = NA, xaxs = "i", yaxs = "i", las = 1,
              axes = TRUE, frame.plot = axes, ...)

.filled.contour(x, y, z, levels, col)
```

Arguments

<i>x</i> , <i>y</i>	locations of grid lines at which the values in <i>z</i> are measured. These must be in ascending order. (The rest of this description does not apply to <code>.filled.contour</code> .) By default, equally spaced values from 0 to 1 are used. If <i>x</i> is a list, its components <i>x</i> \$ <i>x</i> and <i>x</i> \$ <i>y</i> are used for <i>x</i> and <i>y</i> , respectively. If the list has component <i>z</i> this is used for <i>z</i> .
---------------------	---

<code>z</code>	a numeric matrix containing the values to be plotted.. Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>xlim</code>	<code>x</code> limits for the plot.
<code>ylim</code>	<code>y</code> limits for the plot.
<code>zlim</code>	<code>z</code> limits for the plot.
<code>levels</code>	a set of levels which are used to partition the range of <code>z</code> . Must be strictly increasing (and finite). Areas with <code>z</code> values between consecutive levels are painted with the same color.
<code>nlevels</code>	if <code>levels</code> is not specified, the range of <code>z</code> , values is divided into approximately this many levels.
<code>color.palette</code>	a color palette function to be used to assign colors in the plot.
<code>col</code>	an explicit set of colors to be used in the plot. This argument overrides any palette function specification. There should be one less color than levels
<code>plot.title</code>	statements which add titles to the main plot.
<code>plot.axes</code>	statements which draw axes (and a <code>box</code>) on the main plot. This overrides the default axes.
<code>key.title</code>	statements which add titles for the plot key.
<code>key.axes</code>	statements which draw axes on the plot key. This overrides the default axis.
<code>key.border</code>	color for the border of the key <code>rect()</code> angles.
<code>asp</code>	the y/x aspect ratio, see <code>plot.window</code> .
<code>xaxs</code>	the <code>x</code> axis style. The default is to use internal labeling.
<code>yaxs</code>	the <code>y</code> axis style. The default is to use internal labeling.
<code>las</code>	the style of labeling to be used. The default is to use horizontal labeling.
<code>axes, frame, plot</code>	logicals indicating if axes and a box should be drawn, as in <code>plot.default</code> .
<code>...</code>	additional graphical parameters , currently only passed to <code>title()</code> .

Details

The values to be plotted can contain NAs. Rectangles with two or more corner values are NA are omitted entirely: where there is a single NA value the triangle opposite the NA is omitted.

Values to be plotted can be infinite: the effect is similar to that described for NA values.

`.filled.contour` is a ‘bare bones’ interface to add just the contour plot to an already-set-up plot region. It is intended for programmatic use, and the programmer is responsible for checking the conditions on the arguments.

Note

`filled.contour` uses the `layout` function and so is restricted to a full page display.

The output produced by `filled.contour` is actually a combination of two plots; one is the filled contour and one is the legend. Two separate coordinate systems are set up for these two plots, but they are only used internally – once the function has returned these coordinate systems are lost. If you want to annotate the main contour plot, for example to add points, you can specify graphics commands in the `plot.axes` argument. See the examples.

  plot.axes = {})
```

fourfoldplot

Fourfold Plots

Description

Creates a fourfold display of a 2 by 2 by k contingency table on the current graphics device, allowing for the visual inspection of the association between two dichotomous variables in one or several populations (strata).

Usage

```
fourfoldplot(x, color = c("#99CCFF", "#6699CC"),
             conf.level = 0.95,
             std = c("margins", "ind.max", "all.max"),
             margin = c(1, 2), space = 0.2, main = NULL,
             mfrow = NULL, mfcoll = NULL)
```

Arguments

<code>x</code>	a 2 by 2 by k contingency table in array form, or as a 2 by 2 matrix if k is 1.
<code>color</code>	a vector of length 2 specifying the colors to use for the smaller and larger diagonals of each 2 by 2 table.
<code>conf.level</code>	confidence level used for the confidence rings on the odds ratios. Must be a single nonnegative number less than 1; if set to 0, confidence rings are suppressed.
<code>std</code>	a character string specifying how to standardize the table. Must match one of "margins", "ind.max", or "all.max", and can be abbreviated to the initial letter. If set to "margins", each 2 by 2 table is standardized to equate the margins specified by <code>margin</code> while preserving the odds ratio. If "ind.max" or "all.max", the tables are either individually or simultaneously standardized to a maximal cell frequency of 1.
<code>margin</code>	a numeric vector with the margins to equate. Must be one of 1, 2, or <code>c(1, 2)</code> (the default), which corresponds to standardizing the row, column, or both margins in each 2 by 2 table. Only used if <code>std</code> equals "margins".
<code>space</code>	the amount of space (as a fraction of the maximal radius of the quarter circles) used for the row and column labels.
<code>main</code>	character string for the fourfold title.
<code>mfrow</code>	a numeric vector of the form <code>c(nr, nc)</code> , indicating that the displays for the 2 by 2 tables should be arranged in an <code>nr</code> by <code>nc</code> layout, filled by rows.
<code>mfcoll</code>	a numeric vector of the form <code>c(nr, nc)</code> , indicating that the displays for the 2 by 2 tables should be arranged in an <code>nr</code> by <code>nc</code> layout, filled by columns.

Details

The fourfold display is designed for the display of 2 by 2 by k tables.

Following suitable standardization, the cell frequencies f_{ij} of each 2 by 2 table are shown as a quarter circle whose radius is proportional to $\sqrt{f_{ij}}$ so that its area is proportional to the cell frequency. An association (odds ratio different from 1) between the binary row and column variables is indicated by the tendency of diagonally opposite cells in one direction to differ in size from those in the other direction; color is used to show this direction. Confidence rings for the odds ratio allow a visual test of the null of no association; the rings for adjacent quadrants overlap if and only if the observed counts are consistent with the null hypothesis.

Typically, the number k corresponds to the number of levels of a stratifying variable, and it is of interest to see whether the association is homogeneous across strata. The fourfold display visualizes the pattern of association. Note that the confidence rings for the individual odds ratios are not adjusted for multiple testing.

frame

*Create / Start a New Plot Frame***Description**

This function (`frame` is an alias for `plot.new`) causes the completion of plotting in the current plot (if there is one) and an advance to a new graphics frame. This is used in all high-level plotting functions and also useful for skipping plots when a multi-figure region is in use.

Usage

```
plot.new()
frame()
```

Details

The new page is painted with the background colour (`par("bg")`), which is often transparent. For devices with a *canvas* colour (the on-screen devices `X11`, `windows` and `quartz`), the window is first painted with the canvas colour and then the background colour.

There are two hooks called `"before.plot.new"` and `"plot.new"` (see [setHook](#)) called immediately before and after advancing the frame. The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, `get` is called on it from within the **graphics** namespace.)

See Also

`plot.window`, `plot.default`.

grid	<i>Add Grid to a Plot</i>
------	---------------------------

Description

`grid` adds an `nx` by `ny` rectangular grid to an existing plot.

Usage

```
grid(nx = NULL, ny = nx, col = "lightgray", lty = "dotted",
     lwd = par("lwd"), equilogs = TRUE, nintLog = NULL)
```

Arguments

<code>nx, ny</code>	number of cells of the grid in x and y direction. When <code>NULL</code> , as per default, the grid aligns with the tick marks on the corresponding <i>default</i> axis (i.e., tick-marks as computed by <code>axTicks</code>). When <code>NA</code> , no grid lines are drawn in the corresponding direction.
<code>col</code>	character or (integer) numeric; color of the grid lines.
<code>lty</code>	character or (integer) numeric; line type of the grid lines.
<code>lwd</code>	non-negative numeric giving line width of the grid lines.
<code>equilogs</code>	logical, only used when <i>log</i> coordinates and alignment with the axis tick marks are active. Setting <code>equilogs = FALSE</code> in that case gives <i>non equidistant</i> tick aligned grid lines.
<code>nintLog</code>	one or two integers (or <code>NULL</code>), passed to <code>axTicks()</code> when <code>nx</code> or <code>ny</code> are to be determined; effective only with log coordinates.

Value

A list of the x ("`atx`") and y ("`aty`") coordinates at which the grid lines were drawn is returned invisibly.

Note

If more fine tuning is required, use `abline` (`h = .`, `v = .`) directly.
